France might be quoted in a different sense. Her reputation for design and colour, based largely on the past, is upheld by her present skill and refined taste. All French manufacturers do not produce beautiful things by any means, and yet a Frenchman selling in London, the merit of whose goods is quite unknown, will generally, almost always, obtain an entry to the buyer, and receive greater consideration for his wares than the manufacturer or merchant of any other nationality. Helped by his country's known character for refined goods of artistic manufacture, his battle in selling is more than half won by the readiness and courtesy with which he is received by the possible purchaser and by the popular prejudice in favour of his goods. If any proof were needed that this is so, I will here mention the fact that I have frequently seen English-made silks, both cheap and pretty, that have been unsaleable to the English distributor until they have been sold to a Paris house, which has then offered them here under French names at a higher price, and sold them with success. A good reputation is a valuable asset for a nation as for an individual. Does this country possess one in connection with the manufacture of silk goods? In my opinion, it not only has an old-established reputation for honesty in the quality of the goods it manufactures, but it is rapidly building up the still more valuable and lasting one of purity and originality in design and unique taste in the selection and blending of colours; art, in fact, has stepped in to robe our industry with her unfathomable beauties and inextinguishable fame. The movement was begun by William Morris, who included the weaving of decorative silks in his multifarious and wonderful works of art, and by my father, Benjamin Warner, who devoted his whole life to the manufacture of silks and velvets chiefly for furniture and hangings for church purposes, and brocades for Court gowns. He was the only man I ever met who combined an absolute knowledge of the construction of the most complicated fabrics with a sound knowledge of design and an inborn taste for colour.

The splendid pioneer work which these two renowned art-craftsmen—unfortunately now no longer with us—initiated is now being energetically followed up by an increasing number of able and devoted workers, who are daily bringing fame as well as prosperous trade to the artistic section of our silk manufacture, which must and does reflect beneficially on all other branches of silk manufacture in this country. Whether realised or recognised, it matters little—the waves of good influence, like those of bad, spread far and wide, and however unsusceptible we may be to our surroundings, the far-reaching effect of good work remains. Silk does not stand alone in its artistic development. All our industries where art is applied are advancing to a higher standard of excellence, and in almost every industry and handicraft one finds beautiful work being done which is unsurpassed by foreign productions. As an example, I would mention the decoration and furnishing of rooms which is now being done with such exquisite taste by several firms in this country. The display made by these firms at Brussels in 1910 was dignified, classical and beautiful. At one bound it established the character of English decorative art as being higher than it has stood since the days of the Adam Brothers and Chippendale, and quite on a level with, although different from, the best work of the French. Not only has that display brought good business from all parts of the world

Hosted by Google

to those enterprising exhibitors, but it has raised the whole decorative and furnishing trade in this country to a higher plane. Nor does their good influence on our productions end there, for in their efforts to improve, other industries, such as those of metalwork for stoves, brackets for lighting and other fittings, carpets, tapestries, and printed textiles, wall-papers, etc., are stimulated to create better work, and these industries in turn re-act in a similar way on those closely associated with them.

The Brussels Exhibition, just mentioned, recalls the magnificent display of British silks which our manufacturers very pluckily made there. As a demonstration of our ability to make lovely silks of all kinds, it was an immense success, and nothing to equal it of purely British origin had ever been seen before. Some praise of it appeared in the British press, but the real spontaneous and most valuable appreciation came from foreign experts, French, German, Belgian, and others, either casual visitors to the Exhibition, or members of the international jury, whose generous testimony to its sterling qualities I delight in recognising here. Seventeen firms participated in the first display, which was so disastrously destroyed by fire, and in the reconstituted British section nine firms again came forward with extensive and equally meritorious exhibits.

To our King and Queen, patrons of the Silk Association, and ever ready to forward the interests of the British industry, this display at Brussels, synchronising with the all-round improvement in home silk manufacture, must have brought much satisfaction. It affords a practical demonstration that their royal patronage, so readily and continually given, has been attended by definite and beneficial results, and it will be equally gratifying to other enthusiastic workers in the cause of British silks, such as the Duchess of Sutherland, who so kindly placed Stafford House at the disposal of the Silk Association for the Silk Exhibition of 1894, and to the Hon. Mrs. Percy Mitford, who for thirty years has worked strenuously and unceasingly in advocating the use of silks of home manufacture.

The recent history of the silk industry and its present condition having been amply considered, let us now turn our attention to the all-important phase of it—its future.

I have no apology to make, but it almost seems out of place to talk about the future; it is the fashion nowadays to disown posterity, to speak of it in a mean spirit, to cast it aside as having no claim upon us. We forget that to a past generation we are posterity materialised, and that all our privileges and blessings are the direct and immediate outcome not only of the toil, suffering and sacrifice of our predecessors, but of their care, thought and interest in what to them was the future. "Let futurity shift for itself," or "Posterity has done nothing for us; why should we do anything for posterity?" are expressions now heard every day. Such egoism, revolting and unnatural in the individual, will result in national ruin if put into practice. Besides this, we must ever remember that we can no more sever ourselves from posterity than we can cut adrift from the past; everything we do, wise or foolish, will affect the future. The warp in the loom is eternal in its length; it is at present our privilege to weave upon it, and we make good or bad work according to our ability or our determination, but at least it is our duty to leave the loom at last so that those who come after us may do better than us. Bad or indifferent work is mostly the result of ignorance or inefficiency due to the lack of education. Proper education in the silk industry means a thorough training in applied science and art for all those who are later on to control and guide it. A complete course of tuition in the technicalities of silk spinning, dyeing, weaving and finishing, supplies the knowledge of the composition and properties of yarns, such as their strength, nerve, and lustre, which is necessary in determining their adaptability to the various types of cloth, the selection of appropriate dyes for certain classes of silks, either pure or weighted, the knowledge of the manipulation of the warp and weft threads to obtain certain effects in cloth structure, either old or original, the application of design to a suitable make of cloth, the construction of the loom for all classes of plain weaving and for all types of design and processes necessary for the treatment of the cloth when woven.

The training in applied art provides the teaching of drawing of natural forms, particularly of plants and flowers, animals and the human figure, an introduction at least to the bearing of architecture upon design, the study of the recognised styles of design of past periods, and a training in the blending of colours.

The science training provides the body or fabric, the art training the soul or character by which it becomes known, or an individuality which distinguishes it from anything that has ever been made before.

Technical training alone may suffice for the initial stages of silk preparation, but in all its

Hosted by Google

higher branches science and art must go hand in hand, not in dilettante fashion but strenuously, if we mean to establish our silk industry on a firm and indestructible basis. In the past, fifty years ago, whatever the desire, there was not the opportunity for this training; to-day there is much opportunity, but, if anything, we have not fully awakened to the desirability of it. If we had, I am confident that the widest and most complete provision would speedily be made. If we were only as convinced of the vital need of these aids to our industry as we ought to be, and agitate with the same strength and fervency as we do in connection with such questions as the misdescription of goods or national insurance, they would soon be forthcoming.

Two years ago a Departmental Committee was appointed to consider and report upon the functions and constitution of the Royal College of Art, and its relation to the schools of art in London and throughout the country.

The investigations of that Committee led not only to the discovery of the existence of extraordinary conditions in our system of applied art training, but verified in a striking manner many of the objections and complaints that for years have been lodged against the methods of art teaching in our schools.

As the Committee's report has probably not been generally read. I will quote some extracts from it. The first is a very important one, being a clear recognition that handicraft, however meritorious or interesting, must give way to the claims of the manufacturer, upon whom rests the responsibility of maintaining our trade both at home and abroad, and that he can only compete successfully when, through his designer, who is both technically and artistically trained, his goods have superior merit. The report says:

"So far as the principal industries of this country are concerned, the methods of handicraft have long been replaced by those of the factory. It is the factory which supplies the innumerable articles of personal wear and domestic plenishing, constituting the staple of that section of British trade at home and abroad which can be regarded as in any way dependent upon Art. Form and pattern of one kind and another are an important element in the competition between manufacturers of such wares, and tend to become even more important as the differences in mechanical efficiency between trade rivals grow less and less. But they must be form and pattern which are capable of being impressed upon the goods by processes subject to definite mechanical limitations which have to be learned, so that the designer who controls them must study the conditions of the textile power-loom rather than of the embroidery frame."

My next quotation will show you how lamentably the students turned out by the Royal College of Art have failed to bring to the industries the artistic influence which it is their function to provide, and as a consequence much of our designing work is done by foreign designers.

"It might be expected that the College of Art, if the students fulfilled these conditions, would exercise that influence over the artistic trades of the country which it was founded to exercise, and that the designers, who have passed through its course and have obtained the hall-mark of its Associateship, would be eagerly snapped up by business men. All the evidence which we have been able to collect from many and diverse sources of information has brought us to the regrettable conclusion that this is not in fact the case. The needs of the industries are met in various ways. Many designs are supplied by architects or other artists who have turned their attention to industrial art. Many are purchased, especially in the textile centres in and about Manchester and Bradford, from French designers. Thus the Calico Printers' Association, who spend £37,000 a year in designs, maintain sixteen designers in full work in Paris, as well as thirty-eight in England. Designs prepared in England supply the Indian market, those from Paris the markets of England, Europe, and America. The Wall Paper Manufacturers' Combine prefer German designs for technical adaptability, French designs for artistic skill. Of the firms which employ regular designers, some train them in their own drawing offices, others find a supply in the local schools of art. Very few of them ever think of looking to the Royal College, and although some who have tried the experiment have been repaid, we find the opinion widely held that the type of designer turned out by the College is, from the manufacturing standpoint, 'unemployable.' 'For any effect the Royal College of Art has on the designing world, you may take it that it has none at all,' said one witness; or, as Dr. Garnett more sympathetically put it, 'The Royal College of Art, as a college to command the confidence of the trades, has to do a good deal more to win its way.'"

The complaint set out is by no means confined to the Royal College of Art, but is also met with in many provincial towns where industries require the aid of practical and artistic designers. This often arises from a lack of sympathy and co-operation between those who control the administration of art culture and those who are engaged in the manufactures and need the product of the art schools. It also, in part, arises from a deeply-rooted prejudice on the part of many art teachers to machinery and machine-made goods. They know that the mass of gaudy, cheap, horrible rubbish seen in the

Hosted by Google

shops and bazaars to-day is machine-made, which, of course, it is, and therefore they have a horror of machinery, and resent the application of their talents to preparing their students in any way to provide for its requirements.

As a matter of fact, machinery will produce the most beautiful designs as easily as the most detestable, and the refusal of art school teachers to recognise this fact has placed a very heavy handicap on our industries. The report deals with it as follows:—

"We cannot resist the conclusion that the failure of the College to influence manufacturers rests upon something more fundamental than can be explained away as the result of mere prejudice. There is undeniably at present a real want of sympathy between the aims of art and the aims of commerce. This is not in the least because there is any essential difficulty in finding artistic expression through the medium of a machine. As a witness who had had experience as head of the design studio of more than one great distributing house, and been himself exceptionally successful in the training of designers, put it to us, the requirements of a machine are, as a rule, 'by no means unæsthetic,' and, in fact, design for handicraft, just as much as design for manufacture, has to accommodate itself in a greater or less degree to the limitations and conditions imposed by the appliances used. A hand loom or a potter's wheel is, after all, although it allows the hand to contribute more, no less a machine than is a power loom. The same witness's main criticism of the students from the College was that they had acquired a theory and an ideal which 'it was very difficult to knock out of them.' The training of designers in the past has no doubt been too abstract in character, and has taken too little account either of the conditions of machinery or those of material, or of the economics of production. Some of us are disposed to hold that the real problem lies primarily not in any supposed barrier against the production of beautiful things by machinery, for there is none, but in the fact that the public, which the manufacturers serve, does not, for whatever reason, purchase beautiful things, the fault being attributable in varying degrees to the taste of the purchasers themselves, to the taste of the manufacturers, and to the taste of the retail salesmen, with whom, rather than with the purchaser, the actual choice between this pattern and that is supposed to rest. But the soundness of this view must lack proof until the College has provided the manufacturers with designers equally competent from the technical and from the artistic standpoint, and until the manufacturers and the public have shown a deliberate preference for the baser sort of design."

You will notice that part of this quotation dwells on a very important feature of our industrial problem—viz., the taste of the manufacturer, of the purchasing public, and of the retail salesman, who stands between the two. The whole thing summarised amounts to this—that if the manufacturer is able and willing to produce articles of real artistic merit, and the public are desirous of purchasing them, the retailer has it in his power to render abortive the aims of the one and the desires of the other.

It is a very serious matter, and we may well ask the question if the retailer exercises his power in such a way as to check the production and use of artistic goods. It is a very difficult question to answer, but, on the whole, I should say he does not. In many cases the retailer buys with taste and skill, based on some artistic leaning, if not on actual training; in others he rejects beautiful patterns and favours bizarre and *outré* productions. In this matter I think the whole three hang together —I mean the manufacturer, the retailer, and the consumer. All of them equally require a thorough artistic training, which at present but few of them get. The influence of the one reacts upon the other, and as a general upward tendency in the direction of art culture prevails, our production of silk as well as of other things will improve.

The report goes on to say:—

"It is in any case admitted that there is a demand, and perhaps a growing demand, for beautiful goods from a certain limited public, and that individual manufacturers may quite possibly find it to their profit to make a corner in this specialised trade, but this consideration leaves the great mass of textile and other manufacturers, upon which the economic question turns, wholly unaffected. Were all causes of reproach against the Royal College of Art removed, it is not to be expected that a sudden revolution in taste will be worked, or that better-class design will win the confidence of the manufacturers and the appreciation of the public in a day."

Exactly so. Art education, although it but touches the merest fringe of the people, is having an immense influence in the direction of a demand for better things. Remember that art training in connection with our industries does not date back many years. In 1851 it stood almost at zero, and although since then we have accomplished much, the great mass of the population remains untouched by any direct art training, and in its choice of what is good or bad has nothing to guide it but the influence of its surroundings, which in all honesty we cannot claim as providing in the main an atmosphere

Hosted by Google

of artistic thought and leaning. The following quotation from the report is most interesting:—

"As a first step to employment, the students must obviously be equipped to be competent component parts of the industrial machine, as well as artists. Hitherto 'art schools have been occupied in one direction, and the trades in another.' When that unhappy condition ceases to obtain, it will be possible to decide how far the efficiency of the industrial machine is compatible with the cultivation of art. A good illustration of the present divergence between the commercial and artistic attitudes towards design is afforded by the controversy upon 'styles,' which has more than once been argued before us. The luxury of an age which has absorbed archæology, rather than art, desires rooms decorated and upholstered in the historical manners of certain English or Italian or French periods. The work is highly skilled, and demands both erudition and adaptability. The producers complain that the public which they serve will have 'styles,' and that the Royal College of Art students have a wholly negligible knowledge of the history of design. The artist, on the other hand, dislikes the reproduction of 'styles.' For him the study of historic ornaments is rightly an invaluable discipline, provided that it leads not to archæology, but to the formation of a personal style of his own, based upon tradition, but representing an advance upon tradition, and giving expression to his own sense of beauty and fitness rather than to that of the conjured ghost of a bygone century."

To the manufacturers of decorative work of all kinds, and to decorative textiles in particular, this question of styles is an all-important one, and will probably remain so as long as the world lasts. Archæology is therefore of vital necessity to all who are engaged in the trades of building, decoration, and furniture. If we fail at all, it is in the insufficiency of our knowledge of it. Why, then, should our art schools, which are founded and maintained by the State for the express object of assisting the manufacturers of this country by means of art training, ignore it? And yet it is ignored. In fact, it is banned in most of our schools, and, as a result, so-called art students, imperfectly taught in drawing and absolutely uncultured in design, seek in vain for employment in trade *ateliers*. All they have acquired in design is a wretched mixture of poorly-drawn plant form of a semi-conventional nature, with a dash of mediævalism, introducing a meaningless wooden bird or animal, the latter probably the result of badly-directed museum study, the whole thing useless, impossible, and inapplicable for reproduction in any form whatever. Please do not misunderstand me. I do not ask that originality should be discouraged; on the contrary, there is now, as there ever will be, a great opening for new work of distinguished merit, which surely cannot be hindered by a knowledge of historical ornament. But we know that the great mass of art students are not gifted in this direction, and it is therefore little short of criminal to stunt their prosperity by denying them a training which, next to drawing, is the most valuable they can acquire. Really it would be a good thing if most of the schools would concentrate on drawing and leave designing alone. Here and there fortunately we find schools where training is conducted on more practical lines, and in active sympathy with the needs of the industries, and whose work is kept in close touch with the technical side of manufacture. Macclesfield and Bradford are invaluable aids to the silk industry through their art and technical schools, and owing to their direct influence much of the advance in the excellence of silk and other textile production is attributable. Whilst this is generally recognised, much remains to be accomplished. This the report deals with as follows:—

"If the training of designers is to be kept in close relation to the industries, it must in the main be carried on in the actual centres where those industries are located, and where alone the necessary equipment can, without reasonable expense, be made available. There are established and well-equipped schools in most of the great manufacturing centres, and we would urge that each of these should be encouraged to specialise in the needs of its dominant industry, and to obtain the position of a provincial college, to which industrial students might be drawn from the whole area over which the industry is spread, and in which they might receive an advanced training in design with a direct application to the special needs of the special industry. Thus Manchester, Bradford, Kidderminster, Macclesfield, and Stoke-on-Trent would become seats of great monotechnics serving respectively the needs of the cotton, woollen, carpet, weaving, silk and pottery trades, and we would particularly dwell upon the importance of treating the scientific and artistic aspects of technical instruction in two departments of a single college, and thus breaking down the isolation in which a school of art too often stands at present in relation to other educational institutions in its locality."

Following this, let me quote the first two recommendations of the committee:—

"1.—That the training of designers for the manufacturing industries should be specialised, and should be undertaken by provincial colleges of art, each of which, while continuing to provide a general education in art, should devote special attention to the needs of the dominant industry in its locality, and to this end should take steps to associate with its work representative manufacturers and artisans belonging to the industry."

Hosted by Google

"2.—That these provincial colleges should be conducted as departments of colleges which deal with the scientific as well as the artistic sides of the dominant industries in their localities."

To all engaged in the artistic industries, and in silk manufacture in particular, these recommendations are the embodiment of their desire, long and eagerly sought for, to provide education in its most practical form for its most vital needs. If adopted, they will result in the uplifting of our whole industrial attainment to a standard dreamt of, perhaps, but hitherto unapproached by anything attempted or achieved in the past.

If we have a duty remaining, it is to see that these valuable recommendations are carried into effect, and not left unrealised. The vital need at the moment is that our industry should be raised and left no longer entangled in the weeds of past inefficiency, technical or artistic.

I cannot close my paper without referring in all gratitude to the inspiration and example which the long and precious life and high character of our revered chairman, Sir George Birdwood, have set us. His efforts on behalf of the Kashmir Silk Industry date back as far as the year 1861, when he was the first to call attention to the possibility of sericulture in that province of India, which led to its development under the enthusiastic guidance of the late Sir Thomas Wardle. His unflagging interest in the British Silk Industry, his conviction of its present technical and artistic merits, and abounding faith in its future, his great knowledge and abilities in connection with a vast range of subjects, particularly those of a refined and sumptuary nature, and his graceful and learned speeches on all topics, appeal to us and incite our warmest admiration.

To recall Shakespeare's words :—

"He was a scholar and a ripe and good one,
Exceeding wise, fair spoken and persuading."

Or to quote Browning :—

"One who never turned his back, but marched breast forward,
Never doubted clouds would break,
Never dreamed, though right were worsted, wrong would triumph,
Held we fall to rise, are baffled to fight better,
Sleep to wake.

"No, at noonday in the bustle of man's worktime,
Greet the unseen with a cheer,
Bid him forward, breast and back as either should be,
'Strive and thrive' cry 'Speed—fight on, fare ever,
There as here!'"

DISCUSSION.

The Chairman (Sir George Birdwood) said :—I am in the chair this evening, not only because Mr. Frank Warner's subject is silk, but because he is his revered father's son, and has so worthily followed in his father's footsteps in devoting himself to the promotion of the great revival of the silk manufactures of this country after their collapse between 1860 and 1870, until now, alike in artistry and quality, they equal, and, I will be bold to say, surpass, the silk stuffs produced anywhere else in the world. Owing to my connection, through the India Office, with International Exhibitions, I became acquainted with the late Mr. Warner, as with the late Sir Thomas Wardle, so far back as 1871; and from that year the personal friendship between the three of us grew closer and stronger to the last days of their strenuous, straightforward, and most lovable lives. There was another tie between the late Mr. Warner and myself, in that we were both of French descent —he in the direct line of his paternal ancestry. He used to say that, so far as he had traced his forefathers back, they had always been engaged in the silk industry. He himself was born in 1828, and, on the death of his father in 1839, he had at once, as a boy of eleven, to take full charge of the business of the family, consisting of the widowed mother and his five sisters, all directly dependent on him. I could cite from my personal knowledge of the history of our leading London firms, several instances of family businesses being in this way suddenly thrust upon mere boys, and by them transformed into great business houses; another notable one being that of Messrs. Henry Sotheran and Co., which fell into the hands of the late Mr. Henry Sotheran when he was ten years old. And what a test and proof of the highest character, and capacity, and how inspiring a national glory that such triumphs of moral and intellectual worth should be commonplaces of the industrial history of this country! The late Mr. Warner had also other special qualifications for facing so successfully so adverse a fate, in his remarkably refined artistic taste, both in respect of design and colour, inborn of generations of experience in the manufacture of silks; and, again, in a natural modesty that always left him in imperfect content with his work, and intent only on its further improvement. He instantly removed himself from the school he was attending at the time of his father's death, and began to practise himself in designing for silk fabrics, and in card-cutting, and in plain and figured weaving; while, later on, he studied of evenings at the Spitalfields School of Design, one of the first to be established in this country under the direction of the Victoria and Albert Museum, that glorious memorial of the genius of Sir Henry Cole. This practical training in the mechanical and artistic technicalities of his work was one of the secrets of the late Mr. Warner's success in life, not only as a manufacturer of silks of supreme artistic merit, but also as a trader in them. When he,

Hosted by Google

a boy of eleven years, started in life, our "silk manufacturers," as they called themselves, were merely employers of designers, and card-cutters, and weavers; and it was he who changed all this; and so thoroughly that, on the collapse of the silk industry of this country between 1860 and 1870, he forthwith took to manufacturing silk for himself, and from the very outset of the reform he then carried through, it became a source of assured profit to himself, and a timely boon to all the remaining weavers of Spitalfields. It is no exaggeration on my part to say, that no silken textiles, of such excellency in design, colour, structure, and substance, were ever produced in this country before Mr. Warner took the manufacture of them into his own hands; and that to-day the silk manufactures of the United Kingdom are not to be surpassed—and I rejoice to add that the same may be said of our textile manufactures generally, including carpets, and of our porcelain and pottery, and gold and silversmithing—by those of any country of Europe and the Americas. Mr. Warner's efforts were at first restricted to decorative fabrics, but later on they were extended to dress brocades of the richest and noblest types, and with the same creditable and remunerative results; and it was the sumptuous silks Mr. Warner exhibited at Manchester in 1887 that led to the founding in that year of The Silk Association of Great Britain and Ireland, with Sir Thomas Wardle as its first President. Except Mr. Warner's silks, there were no other British silks at that time to give the necessary impulse —*i.e.* the quickening of the enthusiasm of Sir Thomas Wardle and his circle—for the establishment of the Association. The late Mr. Warner was, indeed, one of the great "Captains of Industry" who in our day have given the name of England its most beneficent and enduring titles to fame throughout the commerce of the civilised world. It would be all-sufficient for me to say of the lecturer of this evening, that he is the worthy—I will emphasise it—the brilliantly worthy son of his worthy and worshipful father; but it will be as well to add that he was not only trained to a practical knowledge of the manufacture of silks, but was instructed in the theory of their manufacture, and in the principles of political economy generally at Lyons itself, the very best school of industrial and commercial philosophy in Europe; that he entered the business of his house in 1881; that since 1893–4 he, in the manufacturing department, with his elder brother, Mr. Alfred Warner, in the commercial, have held the entire direction of it; and that, on the death of Sir Thomas Wardle in 1909, he, after a brief tenure of the office by Mr. Boden, succeeded, in 1910, to the Presidency of the Silk Association of Great Britain and Ireland. Indeed, by general and expert education, and matured experience, and wide knowledge of the world wherewith he is preoccupied, and sound judgment, and enthusiasm in his work, and by the subsidiary accomplishments that contribute so much to the perfection of achievement in all great undertakings, there could be no one more competent than Mr. Frank Warner to appear before the Royal Society of Arts on the subject of this evening's paper.

The history of the silk industry of this country is comprehensively outlined in Sir Henry Trueman Wood's paper "Industrial England in 1754" (the year of the founding of the Royal Society of Arts), read before us on April 20th, 1910; while the most interesting details of that stimulating history are to found in Vol. XV.—entitled, "The History of the Walloon and Huguenot Church at Canterbury," and dated 1890—of the publications of The Huguenot Society of London, which have been most courteously placed at my disposal for the purposes of this paper by Colonel Duncan G. Pitcher, formerly of the 3rd Bombay Cavalry, and presently the able Secretary of the Huguenot Society of London. But here I need no more than remind you that England owed her first introduction to the arts and crafts of weaving generally to the Netherlands artisans who were encouraged to settle in this country by Edward III. [1327–99]; that two centuries later an equally warm welcome was extended to the Protestant refugees from France and Flanders by Edward VI. [1547–53], who in 1550 granted them the privilege, still enjoyed by them, to worship in the Western Crypt of Canterbury Cathedral, and by Queen Elizabeth [1553–1603]; that these immigrants were not only weavers of brocades and damasks, and other silken tissues of both high and low grades, but of woollen stuffs of all sorts, "sayes," "bayes," carpets, arras, and other tapestries; and, moreover, included in their number workers in Spanish leather; and in brass in its various applications; and makers of bricks, tiles, and delft; and of paper; and guns and gunpowder; and that it was through the skill, and industry, and high virility of men—who had sacrificed everything on earth, the better as they, in their heresy, mistakenly thought, to serve Heaven—operating uninterruptedly, all through the reigns of Edward VI., Queen Mary, Queen Elizabeth, and James I. [1603–25]—no less than to the contemporary enterprise of the East India Company, and the prowess of our navigators, and naval commanders, that this country, step by step, throughout the seventeenth century, secured that position of industrial, commercial, and maritime supremacy we have ever since maintained, under every strain and stress, unimpaired. By the end of the seventeenth century, 1688–99, the French silks of Spitalfields had become famous throughout the United Kingdom. But, all the same, this now naturalised French industry suffered from the very first from the importations of Chinese and Indian silks, and, still more, of Indian "chintzes" ["painted," cf. *cheetah*], by the East India Company. The silks of India and China were far richer than ours, and the flowered calicoes [so called from Calicut, their first place of export] much cheaper; and, as Sir Henry Trueman Wood has told us, Queen Mary herself [the wife of the Dutch conqueror of England] had a great love for these

Hosted by Google

lovely "painted" cottons from Sadras and Masulipatam; and so, from about 1689-1714, the silk looms of Sandwich and Winchelsea began to be more and more concentrated in Spitalfields, until by 1837, none were, so far as I have ascertained, left in Kent. The commercial policy of universal "Free Trade," adopted by us in 1846, which in the process of the suns raised the British Empire to the greatness and glory it attained under the sceptre of Queen Victoria, at once filled Spitalfields with dismay, and indeed disaster, but, as I have already indicated, thanks to the late Mr. Warner, never drove it to despair; and to-day, chiefly through his intelligence, sagacity, courage, and steadfast endurance, and the discovery by Lord Masham in 1891 of a way of spinning Indian "chasum," as it is so absurdly designated, the manufacture of silk throughout this country has become established on so firm a foundation that, to all outward seeming, it should never again be seriously shaken.

The secret of this great retrieval is that of all human retrievals—the resolute rising of wise and brave men superior to every fate of evil; and it was simply in this heroical way that the more notable of our silk manufacturers, quietly, patiently, and determinedly facing the stark competition to which they have been exposed ever since 1843, by restricting the output of their looms to the production of the highest and costliest denomination of silks—in a word, by specialising in excellency, absolute excellency, in material, and tissue, and colour, and decoration—have at last brought them to a pitch of perfection, where only the gorgeous and resplendent rolls of the deftly-sleided silks from off the looms of Lyons can be set beside them on any equality of footing. This is the redeeming spirit that in every age has inspired the men who have been the makers of human civilisation; and happily it is the spirit that still animates Englishmen in whatsoever they do, be it on the battlefield, or at the cricket pitch. "Play up and play the game" in every struggle of life; and long though the struggle continue, in the end we shall always come out of it with enhanced reputation, joyfully bringing the recaptured "Ashes" with us!

Apart from the controversy between "Free Trade" and "Tariff Reform," the immediate practical problem before the silk manufacturers of the United Kingdom is that of the arrangement of some *modus vivendi* between them and our great distributing houses—our Whiteleys, and our Harrods. I do not ask the manufacturers, or the distributors, to be influenced by any sentimental motives in coming to some such understanding as I am here suggesting, and for years past have publicly advocated. Sentiment, if yielded to in business matters, will only lead you astray—the desire to please each other, the desire to please our Colonies, whose people are far too level-headed to reciprocate such nonsense. Our distributors must stand by the multitude of their buyers, by the poor men like myself. But our distributors should not ignore our manufacturers; and if the latter are not set aside, as men hopeless to bargain with, our manufacturers will soon show that they can make low-priced goods as well as high-priced goods, and far better goods than any foreigner can supply at the same prices. It is in this way that I would have our manufacturers meet our distributors—who at present are the backbone of our Free Trade commercial system—and it is in such an understanding as this, that, in my conviction, both our distributors and our manufacturers will, in the result, find their exceeding great reward; and the people of Great Britain and Ireland an enhanced stability in the main sources of all that makes for our national security and peace, and prosperity, and happiness.

MR. E. W. COX congratulated the author on his most excellent paper, and said he was sure silk manufacturers agreed that they owed him a debt of gratitude for the very efficient manner in which he had demonstrated that within the last decade the silk industry of the country had not only continued in existence, but had made a certain amount of progress. The old question, "Oh! do you make silk in England?" seemed to have lost its point, thanks very much to the work of the President of the Silk Association, whose exhibit at the Brussels Exhibition was the delight and admiration of all the jurors. Personally, as a wholesale distributor, he naturally had to seek the whole world over for goods for his customers, but underneath that trade instinct he possessed a trait which was not very prevalent among some of their friends, namely patriotism. If this country was in a position to manufacture the beautiful silk goods that were exhibited on the walls, the manufacturers ought to be encouraged. He was happy to say that only during the present week he had had delivered to his firm a most excellent sample of English-made goods of the latest patterns, whose colourings were equal to any to be obtained on the Continent, while the price compared most favourably with that of the foreign article. He hoped the Silk Association would induce the manufacturers to do something to show that they really existed; in particular, he hoped they would exhibit at the forthcoming Exhibition. The day was past for hiding their light under a bushel; and the idea that they would have their goods copied before they were properly launched in the market was dead and buried. Those who visited that Exhibition would, he was sure, see an admirable example of what British silk manufacturers could do. Personally, he was of the opinion that there was not a single article at present made of silk that could not be manufactured in this country, although there was no doubt that some of the manufacturers did not know what their mills could produce and had produced in days gone by. He recently had access to a book which contained patterns of manufactures of British silks from 1830 to 1848, and among them was a certain design which took his fancy. He went to

Hosted by Google

the supposed manufacturer, who, however, said in reply to his inquiry that his firm had never made such an article. That particular manufacturer subsequently discovered the old patterns, which had been stored away in a loft, and as a result he had an excellent season's business, through making silk articles of that particular pattern.

MR. F. BENNETT-GOLDNEY, M.P., thought that the Chairman's and the author's remarks were absolutely true, that it was possible to produce at the present time in this country silks and velvets as beautiful as any which had been produced in any other part of Europe. He was glad to think that the Chairman had paid such a kindly tribute to the author's father, who did so much to restore the silk industry in England when it was all but driven out for good. It said a great deal for the strength of the industry that such beautiful silks and velvets as were exhibited on the walls of the theatre were still produced in England—he was almost going to say under a Radical Government, but he must not introduce politics. At the same time he thought it behoved everybody interested in the silk industry to think out things very closely for themselves, so that in the future they might find not only the silk but other industries receiving that kind of protection under which it throve so well. He thought the nation was to be congratulated upon the revival of art as applied to the domestic decoration of the present day. A great debt of gratitude was due to those who distributed the goods as well as to the manufacturers, and the author and other manufacturers were among the first to recognise that obligation. He was delighted to see present a gentleman who had done a very great deal to train the rich purchaser, both on this side of the Atlantic and on the other, in the right direction in connection with the buying of beautiful fabrics and in choosing beautiful colours for their decorations; he referred to Mr. Allom, whose name he believed would eventually be coupled with names as familiar to people to-day as those of the brothers Adam and other eighteenth century masters. As one who had something to do fairly often with the choosing of fabrics, he was very pleased to notice, as the years rolled on, that even in the great emporiums one or two good patterns were now and then found. If he went to Tottenham Court Road, he was now always able to find one good pattern in a shop, and if he inquired where it came from he was always told that it was of English manufacture, and the work of Messrs. Warner. There was one piece of advice he would like to give, which was of even more importance, he thought, than anything that could be said to the manufacturer and distributor. If the rich purchasers of to-day would insist, as many of them in England were doing, upon having English silks, English velvets, and English woven goods, it would not only increase the commerce of the country and its prosperity, but it would enable the manufacturers to hold their own against any foreign competition, wherever it might come from. Really the purchaser was the crux of the problem, and it was therefore a very pleasing thing to notice that so many ladies were present at the meeting. If English ladies only knew that English silks wore a great deal better than foreign silks, and that English silks were now even exported to Paris for the best millinery and the best dresses, they would know that they were in the fashion if they bought English silks, and at the same time they would be doing a patriotic service.

MR. J. H. MURGATROYD (Halifax) desired to add his testimony to the very accurate details given by the author as to the business of silk spinning by machinery, the particular trade which he represented. The service Mr. Warner had rendered to the industry by reading his present paper was only one of the many efforts he had made in the interests of the silk industry of Great Britain and Ireland; and on behalf of the silk-spinning industry he thanked him very much indeed for his work on their behalf.

MR. A. J. SOLLY (Congleton), as a silk spinner, thanked the author for the masterly and interesting manner in which he had described not only the practical but the artistic part of the silk industry. He was glad to say that the silk-spinning trade had not lost ground. Personally, he was the last survivor of a firm started by his grandfather in 1783 for throwing and weaving silk, and latterly silk spinning, and he was glad to say that during the last year his firm had spun more silk than in any year in its previous history. Nevertheless, that did not represent the position which he considered the industry ought to occupy. It only meant that British silk spinners had the leavings of a demand which in the past year was greater than ever before. They now held the same position as a silk-spinning industry that they held thirty years ago, but during that time—it might be under Protection, and it certainly was owing to cheaper labour—an enormous industry had grown up abroad, which was at least ten or twenty times the size of the industry in this country. He was not one of those who thought that the struggles of those connected with the silk industry in this country would be lessened in the future. Even now they were faced with very serious competition from Japan, which had already beaten them in some neutral markets, such as India and the Far East; and without being pessimistic he thought British manufacturers would have a great struggle with the Japanese in the future, perhaps far greater than they had had with the Continental spinners in the past. To face that it would be necessary to rely not on the artificial help but the friendly help of the Government, and the good sense and friendly help of the workpeople and the trades unions. Greater freedom was required from unintelligent legislation, and more freedom was required in connection with labour. He did not think any Government, either Conservative or Radical, had sufficiently

Hosted by Google

understood the processes of manufacture for which it had legislated, and he very greatly regretted that Sir William Priestly, one of the Vice-Presidents of the Silk Association, had not yet been able to secure the object of his ambition in going into Parliament, namely, the foundation of a Ministry of Commerce. The present Insurance Act would tell very hardly on a trade like the silk industry, which depended so much on female labour, and this was another argument in support of his contention that more intelligent legislation was required on questions connected with the trade of the country. He pleaded also for greater intelligence on the part of their customers, the ladies and the public in general. He hoped that those who bought silks in this country would lose the prejudice, which still lingered to a certain extent, in favour of French or Italian silks; and he also hoped that when they paid for silk they would see they got it, and would not be put off with material made of inflammable wood-pulp or with a silk dress made of tin. He hoped that there was a bright future in store for the silk industry, but he could not share the view of some gentlemen who had lately spoken in public, that its condition was at present as rosy or as satisfactory as had been stated. A speaker had recently been reported as saying that the silk trade of Macclesfield was booming as never before. Personally, he lived in the next town to Macclesfield, and knew that during the past six months the weaving trade in Macclesfield had been worse than at any time during the past ten years; and at the present moment not one in ten of the manufacturers knew what would happen in the next few months, owing to the present unfortunate labour troubles and the rumours of war, which were very disastrous to a trade connected with a luxury.

Mr. Charles C. Allom thought that the paper was one of immense value, and that it would serve as a work of reference in the future to all connected with the silk industry in this country. Apart from the Chairman's illuminating remarks, he thought Mr. Bennett-Goldney had referred to one of the most important points connected with the question, namely, the education of their patrons. There was no better customer for the silk industry than a lady, but her custom depended upon whether the goods were new and of the latest type of fashion. It was not much good preparing goods of wonderful artistic merit if the ladies of the present day simply went in for materials that were apparently quite new. He was afraid that ladies required to learn more of the artistic value of silk goods; when they did so a greater encouragement would be given to the art side of the industry. So far as the actual technical side went, there was not the smallest doubt that this country stood second to none in the world, but it was a most remarkable thing that hardly any of the designs were the direct outcome of British art. The author largely owed his success to the fact that he knew what the taste of the well-to-do public was, and the patterns which were most popular related mainly to styles of the past. Mr. Warner had, with great power of selection, shown specimens at the meeting of the wonderful work of the past generation. There was a silk shown which passed as Adams' silk, but which certainly was never known in the days of the Adams; and there were many others that had their origin in Mr. Morris's studio; but on looking at all the specimens he thought that Mr. Morris could not hold his place amongst the many other beautiful patterns that were exhibited.

Mr. W. R. Fox said it was in recognition of the great services which the author, and his father before him, had rendered to the industry that he was elected straight on to the Court of the Weavers' Company, an honour he was sure all would agree in thinking was thoroughly deserved.

The Chairman remarked that it was entirely owing to the energy of the author that when the British Section at the Brussels Exhibition was destroyed by fire, it was immediately rebuilt; as a matter of fact, Mr. Warner began to rebuild the section the very next morning.

A resolution of thanks to Mr. Warner for his paper was then carried unanimously.

Mr. Frank Warner, in reply, thanked the Chairman for the very kind remarks he had made with regard to himself, but even more he desired sincerely to thank him for his kind references to his father. He assured the Chairman that the family felt that their father should ever be recognised, and the kind words which had been spoken by the Chairman would have a new measure of happiness for himself and his family. It would have given some spice and flavour to the proceedings if his paper had been criticised, but as it had not it was only possible for him to thank all the speakers for the many kind things they had said, not only in connection with his own private work, but also the work of the British Silk Association. In conclusion, he wished to express the hope that all present would as heartily support the forthcoming Exhibition as they had supported him that evening.

JAPANESE VEGETABLE ISINGLASS.

Japanese isinglass, or agar-agar, is made from six kinds of seaweed, the best qualities of which are found on the coasts of the Provinces of Izu, Tosa, and Sado, and are known as Izu, Nanbu, Misaki, Onikusa, Egokusa, and Hirakusa. At the close of summer the seaweed is bought up by wholesale dealers in Osaka, and stored there in "go-downs" until sold to the manufacturers. The manufacture of vegetable isinglass, as its Japanese name, "Kanten" (cold climate), would imply, can take place only in the autumn and winter, as warmth and rain spoil the product. The process is simple, and the utensils employed are primitive. The factories are situated at Ibaraki, in the mountains between Osaka and Kyoto, and at Nishinomiya, between Osaka and Kobe. The process of manufacture, according to the United

Hosted by Google

States Consul at Kobe, may be described as follows:—The seaweed is first crushed, each kind separately, to remove shells or other adhering matter, and then washed clean with water. The washed seaweed is placed on a mat and dried until its colour becomes white by the action of the sun, frost, and dew. This operation takes place during September and October, and when bleached the weight of the seaweed is decreased nearly one half. After bleaching, the six kinds of seaweed—in the proportion of Izu, 4; Egokusa, 4; Misaki, 3; Hirakusa, 3; Nanbu, 4; and Onikusa, 2—are all put together in a boiler and cooked for about fourteen hours, until they have become soluble. The liquid is then strained through a sack and a box with a bamboo sieve on one side, from which it runs into a container. From the container the liquid is ladled into trays about three and a half feet long and three inches deep. After remaining in the trays about twelve hours, these are placed on a low stand, and the isinglass is cut into strips three inches wide and fourteen inches long, with a knife and ruler. These strips are then put into a long closed wooden box (the ends of which are three inches square, one end being open and one filled in with a wire sieve) and pushed through the sieve end in the form of long fine strips. The isinglass is then placed on a low stand, which is covered with a clean mat, and dried in the sun during the day and frozen during the night for two or three weeks during the months of January and February, being watered at midnight. The quality of the isinglass depends upon the weather during this time, the best being made when it is clear and cold, the poorest when it is warm and rainy. When the isinglass is bleached sufficiently it is compressed and packed in Japanese matting, tied with straw rope. The very best quality is all exported to China, the No. 1 quality that is shipped to America being equal to the No. 2 that goes to China.

THE PREPARATION OF WEST-PHALIAN HAMS.

Westphalian ham, more or less famous throughout the world as a German table delicacy, is given its peculiar piquant taste by the use of juniper berries in smoking the meat. The juniper shrub is indigenous to north-western Germany, and so plentiful, especially in Westphalia, that to its presence is due the growth, during the past centuries, of two principal industries, the distillation of gin and the preparation of hams. According to the most authoritative information obtainable, Westphalian hams are prepared in the following manner. The carcasses are cut in such a way as to retain the whole ham bone, together with the hip. The hams are then rubbed thoroughly with a solution of one hundred pounds of salt to one pound of saltpetre, when they are placed on cement floors, or in vats, and thickly covered with salt. They are allowed to lie in this solution for a period of two weeks, and then placed in another receptacle with a 22 per cent. solution of brine. They remain in this solution for a period of eighteen days, their position being changed from day to day so that the hams at the bottom are brought to the top. At the expiration of eighteen days they are removed from the brine and packed one upon the other in a cool dry cellar for four weeks, during which time they are supposed to ripen, that is, to become tender and take on colour. They are then cleaned with a stiff brush in lukewarm water and allowed to soak in fresh water for twelve hours. They are then ready for the smoke-house. The smoke-houses consist sometimes of two, and sometimes of three stories, the fire being kindled in the lowest, and the meat hung in the second and third, to which the smoke ascends through holes in the flooring. Westphalian hams are invariably smoked over a bright fire made of beechwood only, except that juniper twigs and berries are constantly thrown on the fire. Beechwood sawdust is thrown over the fire in case it becomes too strong. The smoking process requires on an average about eight days.

THE POTATO-FLOUR INDUSTRY OF GERMANY.

The great bulk of the so-called potato flour (kartoffelmehl) that is sold retail in Germany for cooking purposes, is simply finely ground and sifted potato starch. There is, however, a flour obtained by grinding and bolting dried potatoes, that is a comparatively new product. In 1901, when the potato crop of the country reached the enormous total of 53 million tons, efforts were made to discover practical and economical methods of preserving the potatoes, so that the surplus could be stored and utilised in supplying future demands. Prizes were offered, and a number of processes were submitted, in the more important of which the potatoes are treated by steam, forming what are called "kartoffelflocken," or potato flakes, which can be used for cattle food, for distilling alcohol, for making starch, and for other purposes for which potatoes are used, or they can be ground and bolted for human consumption. In the Tätosin process for the production of flakes, the raw potatoes are washed in a washing machine commonly used in distilleries or starch factories, and then conveyed to a steamer erected over the drying apparatus, where they are cooked by means of low-pressure steam, as if the potatoes were to be used for cattle food. The American Consul at Berlin states that the drying apparatus proper consists of two smooth hollow cast-iron revolving drums about 4 feet long and 2 feet in diameter, each with a clearance of about ·039 inch. The drums are supported upon a cast-iron framework, on the top of which there is an iron hopper fitted at the bottom with emasculators or crushers. The drums are heated by steam led through a pipe passing through their axes. The interiors of the drums are ridged longitudinally. Condensed water is taken from the drums by small pipes, and returned

Hosted by Google

to the boilers. The potatoes, after being steamed, are allowed to fall into the hoppers and through the emasculators, where they are reduced to pulp, and in this shape are forced on to the drying drum. The drums turn in opposite directions at five revolutions a minute. The heat drives off the moisture of the potato pulp, leaving a firm mass that is scraped off by means of knives set parallel to the main axes of the drums. The dried mass falls into a spiral transporter fitted with revolving arms, where it is broken into flakes and conveyed to the packing room. In other processes of preserving potatoes used in Germany, the tubers are cut into discs or small pieces and dried by hot air. The method described above is, however, that most in use. At present there are four hundred and thirty-six plants established in Germany for drying potatoes, with an estimated production annually of about 135,000 tons. In the production of ground potato flour the potato flakes are ground and bolted. There are but few concerns that manufacture the flour, each having its own process. The flour is a yellowish-white product, rich in carbo-hydrates. According to experiments made by the "Institut für Gärungs-Gewerbe" in Berlin, the principal constituents of the flour are—water 10·69 per cent., protein 6·59 per cent., fatty substances 0·23 per. cent., non-nitrogenous substances 78·73 per cent., raw fibre 1·18 per cent., and ashes 2·58 per cent. The flour is used principally by bakers for adding to rye and wheat flour in making bread. The proportion for wheat bread is 5 to 10 per cent. of the ground potato flour, and for rye bread the amount can be increased to 15 per cent. It is claimed that the addition of the ground potato flour to the rye or wheat flour, gives the bread a good flavour, makes it more digestible, and keeps it fresh for a comparatively long time. Ground potato flour in Germany is known to the trade as "Walzmehl," "Kartoffel Walzmehl," and "Fiddichower Walzmehl."

EMPIRE NOTES.

British Naturalisation.—In the King's Speech it is stated that a Bill will be introduced to give effect to the unanimous recommendation by the last Imperial Conference, for the amendment and consolidation of the law relating to British nationality. The draft of the proposed measure has been sent by the Colonial Office to the Governments of the Oversea Dominions. The main provisions are that an alien may apply for naturalisation as a British subject if he has lived for five years continuously within His Majesty's territory, is a person of good character, possesses an adequate knowledge of the English language, or of any other language recognised in any dominion as on an equality with English, and is prepared to take the oath of allegiance. The proposed law, however, will only become operative after the local legislatures of the self-governing dominions have adopted it. The ordinary right to be called a British subject applies to everyone born within His Majesty's allegiance, or who, at birth, was the child of a British subject, on the paternal side, or was born on a British ship whether in foreign or territorial waters.

The Australian Commonwealth Bureau of Statistics.—An interesting statement has been made by the Commonwealth Statistician in regard to labour statistics. He says: "Considerable progress has now been made in connection with the organisation of the labour and industrial branch of the Commonwealth Bureau of Census and Statistics. This branch is being established with a view to supplying prompt and accurate information as to wages, hours of labour, conditions of employment, prices, unemployment, cost of production, and numerous other matters peculiarly of labour and industrial interest. Agents of the new labour branch have now been appointed in more important industrial centres of the Commonwealth, and the cordial support and co-operation of a majority of the trades unions and other labour organisations have been obtained. Steps are also being taken to obtain much more complete information from manufacturers and others than has hitherto been available, and the systematic collection of returns as to retail prices throughout the Commonwealth is now being initiated. Such questions as unemployment, strikes and lockouts, the natural wealth and its distribution, the cost of living, house rent, and the working of the various laws more directly affecting labour, are receiving special attention. A considerable amount of organising work yet remains to be carried out, but it is hoped to complete the main features of the scheme during the current year. Individual persons, companies, and organisations furnishing returns in connection with the scheme are protected by the fact that all the information is treated as strictly confidential, and the particulars given will be grouped together for publication in general form for allied trades." The question of publishing the returns in a suitable periodical is under consideration. The system instituted should prove of great utility to manufacturers and employers of labour as well as to employees.

A Valuable Queensland Fruit.—Among the indigenous fruits of Queensland, the paw-paw is rapidly gaining popularity. It is a species of tree melon, and the flavour is delightfully refreshing, though quite different from the melons known in this country. On being cut, the rind is found to be thinner than that of the ordinary tree melon. The flesh is either pink or yellow, and in the centre are many small round black seeds. It rivals in flavour the durian and the mangosteen of other and tropical countries. The leaf is said to have the effect of causing tough beef-steak or other meat to become tender, when wrapped in it. The paw-paw has for many years been the source of the pepsin used in pepsin tablets and pepsin gum. Real pepsin is obtained from the stomachs

Hosted by Google

of ruminant animals, while the product of the paw-paw is a papoid compound possessing practically the same qualities as pepsin. The substance is obtained from the fruit just before it reaches maturity, when four longitudinal cuts are made through the skin. When this is done there oozes out a quantity of white juice resembling milk-weed in appearance. After this liquid has been collected in receptacles, it is distilled, and the residue, a white powder, remains. An eminent Queensland physician has discovered that an ointment made from this fruit possesses medicinal healing qualities. It has proved valuable as a cure for burns, scalds, and other injuries of the skin.

Australia's Trade with India.—Australia has in India a most profitable oversea market for some of the natural products of the country. Trade has been encouraged and followed up assiduously for a number of years, and at the present time business is on a sound footing with every prospect of further development. Australia has by far the largest share in the supply of horses for India. Out of a total of 7,552 horses, valued at £220,166, imported into India during 1910, 6,179, valued at £181,491, came from Australia. Most of the rest (881, valued at £19,041) came from Asiatic Turkey, by way of ports in the Red Sea and Persian Gulf; 67, valued at £1,340, came from New Zealand; the remainder (365) from Great Britain and other countries. The exports of timber from Australia to India were valued at 328,387, consisting mainly of railway sleepers, valued at £289,007. Most of this trade is done by West Australia, which is stated to be pushing the business very energetically. The value of the fruits and vegetables imported from Australia was £5,520, and of grain and pulse, £5,171; of coal, £27,842; of wool and woollen goods, £22,520; and of tallow, 5,210. During the year Australia purchased from India a considerable quantity of jute and jute bags.

Canadian Mining.—The Department of Mines at Ottawa has recently issued a report, in which it is shown that the mineral production of Canada for the year 1910 was 16 per cent. above that of 1909, and was the largest increase in any one year since 1886, the first year in which statistics of the whole of Canada were collected by that department. The progress that has been made in the interval may be judged from the fact that, while in 1886 the value of the mineral production was 10,221,225 dollars, the value in 1901 was 106,823,623 dollars. From 1886 to 1896 the returns showed an increase of over 100 per cent., but in the latter year the Yukon district began to contribute largely to the gold production, so that during the next five years a further increase of 200 per cent. above the returns of 1896 was recorded. The next three years indicated a slight falling off, but from 1904 the production rapidly increased to the present high standard. The production of metalliferous products in 1910 was valued at 49,428,873 dollars, being 46 per cent. of the total mineral output, and an increase in value over the previous year of 5,282,032 dollars, or nearly 12 per cent. The value of non-metalliferous products (excluding structural material and clay) in 1910 was 37,757,158 dollars, being 35 per cent. of the total mineral output, and an increase of 6,615,907 dollars, or 21 per cent. in value over 1909. The value of production of clay, lime, stone, and other structural materials in 1910 was 19,627,592 dollars, or 18 per cent. of the total production, and an increase of 3,094,243 dollars over 1909. Amongst the most important minerals giving the above returns, coal occupies first place, contributing about 29 per cent., followed by silver, which yielded 16 per cent. of the total production.

Canada's Telegraphs.—The telegraph systems of Canada are worked almost exclusively by public corporations, and the central Government operates only a small percentage. In point of fact, the Government's mileage is only 150¼, against 155,000 owned and worked by the corporations. The Government lines are not competitive with the others; they are run through sparsely settled districts, and are not intended as revenue earners, their object being to supply cheap and efficient communication to the settlers who are developing new lands for agricultural and commercial enterprise. When a railway enters one of these districts, the Government either transfers or sells its line. In cases where messages have to pass over Government and other lines, special arrangements are made to reduce to a minimum the double cost of the double transmission, and the harmonious co-operation between the Government and the railways enables the settlers, who are on the outskirts of Canadian civilisation, to secure, at practically minimum rates, inter-communication with the centres of commerce. An interesting fact in connection with Canada's telegraph systems is that no charge is made for names and addresses. By this means, full and complete direction is obtained.

The Reconstruction of the Welland Canal.—An important announcement has been made at Ottawa to the effect that the Government has decided to reconstruct the Welland Canal. The depth of this waterway is to be increased to 22 feet, thus giving a depth sufficient for navigation from the head of Lake Superior to within 100 miles of Montreal. When this alteration is complete it will enable Canada to compete successfully with the new Erie Canal on which the United States is spending some hundred million dollars. The approximate cost of the undertaking to the Canadian Government will be somewhere in the neighbourhood of £6,000,000 sterling. The chief object in deepening the Canal is to facilitate the east to west traffic in grain and merchandise. It will also considerably cheapen the cost of transportation of wheat from the western plains to Montreal. It is also proposed to deepen and widen the last 100 miles, so that it will be possible to bring grain direct from

Hosted by Google

the Great Lake ports right into Montreal. The latter project, however, is not contemplated immediately. Transportation experts have advised the Government that the reconstruction of the Welland Canal is more important than the Georgian Bay Canal scheme. Work will be commenced on the Welland Canal during this year.

South Africa and Immigration.—Much hostile criticism has been levelled at the Union Government on account of its apparent apathy on the question of immigration. Critics are of the opinion that South Africa should inaugurate a policy on similar lines to that of Canada or Australia. But all who are acquainted with South Africa must realise that a general indiscriminate policy would not be to the best interests of that country. Colonel Leuchars, Minister of Commerce and Industries, in a recent speech on the subject, said that the conditions in South Africa were so utterly different from those of Canada or Australia, that the same conditions of immigration would be impossible in that country. Dealing, however, with the need in South Africa for white people, he said that since the last census the Government had been most anxious about the small increase of the white population and the large increase in the coloured. But he wanted to encourage the right class of men, with a certain amount of capital, for which purpose a Land Settlement Bill would be introduced giving the Government similar powers to that of the Natal Act. This measure, since the delivery of Colonel Leuchars' speech, has been adopted by the South African Parliament, and a loan of five millions is to be raised in order to give it effect.

CORRESPONDENCE.

THE TRAINING OF CRAFTSMEN, DESIGNERS, AND TEACHERS OF DESIGN.

With reference to the article on the above subject in the *Journal* of the 16th inst., it appears to me that several points are mentioned which require elucidation. The new Board of Education regulations are evidently meant, as the article suggests, to check the flowing tide of students, artists and craftsmen who are taking to the teaching profession as a means of livelihood; and also to render the training of the teacher such as to ensure that only keen and able students shall survive the tests.

Whether the new curriculum is a good one can only be judged by experience; that it is a stiff one, can hardly be disputed. One can only ask whether the art teacher's salary is to be raised proportionately with the status of the teacher's qualifications? The present condition of the art teaching profession is economically wrong. There are many skilled and able artists and craftsmen teaching at an absurdly inadequate wage, because a market for modern art and craft work hardly exists, and they have to accept a scale of remuneration which is in no way commensurate with their ability. Educational authorities have reaped the benefit of this economic condition. They are well aware that for any decent posts, however low the salary, a crowd of excellent candidates will apply. The art teaching profession at present consists of free lances and orthodoxly trained art teachers, and it would be interesting to know the opinion of educational authorities as to which class the more efficiently fills the needs of art education. It would seem that they consider that a teacher should be trained along fixed lines; that art—that is, beauty, fitness, design, construction and expression—can only be developed by the student of pedagogy and the historic styles, the "great reality" being that no amount of excellent teaching will produce vitality. The only way to put life into art is to create a demand for that which is right by doing that which is vital, that which is *needed;* and apprenticing the beginners to the "master-builders" who are responsible for such public work. We have been too content to subsidise our educational institutions, when what is really needed to-day is the subsidising of organised work. To *do* that which is vital has ever been the only way of gaining true knowledge. The whole world of art to-day suffers from one thing only—the lack of opportunity. Subsidise the right opportunities, and systems of training may take care of themselves. I, for one, would cry a truce to all theories. Let us have work.

I might ask, by the way, how, under the new regulations, will teachers be found to fill the numerous posts for elementary art teaching? Will the *fully* qualified teachers be expected to take such posts at the present rate of salary? With respect to the younger generation of craftsmen who are being launched on the world, I have always understood, from those in close connection with our technical institutions, that the trouble is that their general taste and desire to do the best work is far too high for the labour market requirements, and it generally results in the youth degenerating into something little better than the ordinary trade worker.

There are many other points which I am tempted to question in relation to our educational systems, but the bedrock of our difficulties is the need of vital work, on a large scale.

DUDLEY HEATH.

GENERAL NOTES.

THE CONSUMPTION OF MEAT IN ITALY.—The consumption of meat in Italy has risen, during the last seven years, nearly fifty per cent.—that is to say, from twenty-one kilograms per head of the population in 1903, to thirty kilograms per

Hosted by Google

head in 1910. The increased demand for meat, on the one hand, and the falling off in the number of cattle raised, are no doubt the principal reasons for the high prices of meat in Italy at the present time.

THE GROWTH OF CANADIAN TRADE. — The monthly reports of the Department of Trade and Commerce of Canada are amongst the most exhaustive of their kind published by any Government. Although they consist almost entirely of statistical tables, they illustrate very strikingly the rapid growth of the trade of the Dominion. The exports of coal do not increase very rapidly, being only 1,826,339 tons in 1910, but copper shows a big rise in the last twenty years from 10,994,498 lbs. in 1891 to 57,536,116 lbs. in 1910. The export of salted fish varies somewhat, but at 773,401 cwts. is much what it was in the 'nineties. The export of canned lobsters is less than it was ten years ago, but canned salmon amounted to 34,656,097 lbs. last year. The export of pines has fallen off very considerably, and of spruce and other deals to some extent, but planks and boards show increases. The value of furs, dressed and undressed, amounts this year to $4,277,744. The export of bacon and hams, and butter, and in a less degree cheese, show remarkable decreases. In 1903 the export of hams amounted to 141,956,909 lbs., last year to 58,874,525; of butter, taking the same year, 34,128,944 lbs., but last year only 4,615,380; of cheese, in 1903, 229,099,925 lbs., last year only 180,859,886. The export of apples has increased considerably, and while in 1900 the export of these was only 16,844,650 bushels, last year it was 49,741,350 bushels. Perhaps the most remarkable increase of all is in wood-pulp. The figures only go back to 1890, when the total value of wood-pulp exported was $168,180, last year it was $5,204,597.

THE PITH-GRASS INDUSTRY OF FORMOSA.—In Formosa pith grass is found in the prefectures of Shinchiku, Toyen, Taihoku, Giran, Taito, Karenko, Ako, and Taichu. The total production annually in these districts is stated to be between 225,000 and 300,000 pounds, but actually it amounts to a little less than that. The districts where the grass is grown are situated in the savage territory, hence production is not only limited, but gathering the grass is a hazardous occupation. Formosa pith grass is divided into two kinds, high and low hill products, which are again subdivided into seven grades, according to quality. There are twenty pith-paper manufacturers in the town of Shinchiku, and one or two in Daitotei. The former town has naturally enjoyed a monopoly of the trade. Moreover, because of its nearness to the district of production, it has greater advantage in selecting materials than other districts. This condition assisted the growth of the trade, and gave a living to hundreds of native workmen. Formerly the pith-paper sent to Japan was used mostly for artificial flowers, but recently it has been employed in the manufacture of picture cards. In foreign countries, especially in France, it is utilised in fashioning hats and ladies' bonnets. In America it is used in artificial-flower making. Chinese girls are adepts in flower making, and produce such artistic creations that the practised eye cannot detect the artificiality. Lately the pith-paper market has been much disturbed by attempts on the part of a company to control the local production, and by the introduction of an imitation paper. The total export of pith grass from Formosa in 1910 was 30,000 pounds.

COTTON-GROWING IN THE DOMINICAN REPUBLIC. —Although the cultivation of cotton in Santo Domingo is a new industry, the fibre is already assuming importance as a factor of agricultural wealth and as an article of export. About three years ago seed imported from the United States was distributed by the Government among the small planters of the provinces of Monte Cristi and Santiago, and the success attained recently led many of the more important agriculturists to abandon other products for this more remunerative one. This was aided also by failure in the tobacco crop. The Government continues active in stimulating the cultivation of cotton by the distribution of seed, literature dealing with the subject, and personal demonstration when practicable. Indications point to the district known as the "Cibas," particularly in the provinces of Monte Cristi and Santiago, as that most adapted to cotton production. Here there is a geological composition best suited to the cultivation of cotton. Rainfall in the northern part of this district is not very plentiful, and it is thought that this will eventually necessitate moving towards the east. The variety of cotton produced is sea-island mixed with an indigenous kind of seed. Gins are in operation in Monte Cristi and Puerto Plata.

THE PRODUCTION OF ALCOHOL FROM HENEQUEN WASTE.—An invention, which will be of great interest to the planters of henequen or sisal hemp in particular, as well as of practical utility to the world at large, has lately been patented by a native of Tabasco, Mexico, but resident for some years in Yucatan, for utilising the residue of the maguey, after the fibre has been taken, for the manufacture of alcohol. In the process of extracting the fibre the "flesh" of the leaf is scraped off by machinery, and this, with the exception of a small portion used in the manufacture of packing-paper, has been, heretofore, simply thrown on the rubbish heap. It has been found, after years of experiment, that this waste, together with the juice which escapes during extraction of the fibre, will produce, according to the American Consul at Tapachula, a good, merchantable alcohol. The raw material is placed in tanks with water and allowed to ferment for two days, after which it passes into a specially-arranged still. For some time the spirit produced was unsatisfactory, both as to taste and colour, but the late tests, made in the presence of some three hundred of the most prominent business men of Yucatan,

Hosted by Google

were said to be entirely creditable to the inventor. With the immense territory devoted to the culture of the henequen plant in the peninsula of Yucatan, and the yearly increase in the number of acres planted in that State, there should, it is said, be a practically unlimited supply of the raw material. At the same time the multiplicity of uses to which alcohol is now put ensures a constant demand.

The Production of White Arsenic in Spain.—In north-western Spain there are several mines of arsenic pyrites from which white arsenic is now being manufactured. The principal mine, the San José, is situated near Castro del Rey, where the following method of manufacturing the arsenic is employed. The first operation after the pyrites are mined is the thorough pulverization of the ore in a crushing machine, which reduces the lumps of mineral to the size of one-fifth of a cubic inch. It is then passed into the furnaces. The latter consist of a revolving cylinder twenty-nine feet in length and five feet in diameter, whose interior is protected by refractory bricks laid in the form of a spiral, so that the mineral may pass slowly along its entire length and be continually exposed to the action of the heat. One of the ends of the cylinder fits into the fire pit and the other end into a condensing chamber, which, in turn, is connected with a series of ten other chambers arranged in zigzag fashion, which completes the required system of accumulation. During the operation the gases given off pass through the series of chambers, each of which is divided into various compartments, and are thereby condensed, depositing upon the walls of the compartments the white powdery substance called arsenic floss. This article is then gathered from the various chambers, but in its actual state is not marketable on account of its colour, which is dark grey. In order to whiten and refine the powder it is necessary to subject it to another treatment, the result of which is pure white arsenic. This is then pulverized, sifted, and packed for exportation.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

February 28.—H. A. Roberts, M.A., Secretary of the Cambridge University Appointments Board, "Education in Science as a Preparation for Industrial Work." Principal Sir Henry A. Miers, M.A., D.Sc., F.R.S., will preside.

March 6.—T. Thorne Baker, "Some Modern Problems of Illumination: The Measurement and Comparison of Light Sources." James Swinburne, F.R.S., will preside.

March 13.—Professor Ernest A. Gardner, M.A., "Greek Sculpture."

March 20.—F. Martin Duncan, "The Work of the Marine Biological Association." P. Chalmers Mitchell, D.Sc., LL.D., F.R.S., will preside.

March 27.—Theodore E. Salvesen, "The Whaling Industry of To-day."

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

March 14.—E. A. Gait, I.C.S., C.I.E., Census Commissioner for India, "The Indian Census of 1911."

April 25.—Sir John O. Miller, K.C.S.I., "The Central Provinces."

May 16.—Neville Priestley, Managing Director, South Indian Railway, "Indian Railways."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

March 26.—Leonard Lovegrove, "British North Borneo."

May 7.—Alan Burgoyne, M.P., "Colonial Vine Culture."

May 21.—The Hon. J. G. Jenkins, "Australian Railways."

Cantor Lectures.

Monday evenings, at 8 o'clock:—

Luther Hooper, "The Loom and Spindle: Past, Present, and Future." Three Lectures.

Syllabus.

Lecture I.—February 26.—*Primitive Looms and Spindles: Prehistoric, Ancient, and Modern.*—The loom and spindle almost universal—Modern spinning and weaving machinery all constructed on ancient principles—Traces of prehistoric spinning and weaving—Simplicity of primitive tools and appliances—The simple textures of prehistoric cloth—The simplest loom and its essential parts—Modern and prehistoric webs compared—The spindle of all time—Advantages of *distaff and spindle* spinning—Modern distaff spinners—Spinning wheels—Peculiarity of primitive and ancient European looms—Greek and Egyptian methods of weaving—Egyptian, Persian, Roman, Brussels, and modern French and English tapestries.

Lecture II.—March 4.—*The Handloom for Automatic Weaving, Plain and Ornamental, and the Modern Spindle.*—Leonardo da Vinci's sketch of the spinning wheel *flier* and *bobbin* attachment—Its general adoption in Europe for hand spinning—Varieties of the motion developed—Inventors of spinning machinery—Hargreave's *Jenny*, Arkwright's *Waterframe*, Crompton's *Mule*, and others—Weaving in ancient China—Horizontal looms—Indian looms—Old English and other looms for silk weaving—Chinese silk loom—Invention of satin weaving—Looms for weaving small designs—Double *harness* weaving—Long- and short-eyed *leashes*—Chinese *draw-loom*—The *comber board*, its great importance—The *pulley box*—The tail of the loom—The *simple*—The *tie-up* of the design—The *divided* comber board and other arrangements for *tissue* weaving—European draw-looms—Examples of draw-loom woven textiles of various periods.

Hosted by Google

Lecture III.—March 11.—*The Modern Loom for Plain and Ornamental Weaving and its Future Development.*—Eighteenth century inventions compared with those of earlier periods—The drawboy—The drawboy machine—The Jacquard machine or *draw-engine*—Kay's *fly shuttle*, its great utility and unexpected value—The first power-looms—Application of steam power to the loom—General adoption of the factory system in textile industries—Comparison of hand and power-looms as regards quality and speed of weaving—The effect of machine weaving on the workers—Defects of the power-loom—Electricity as applied to the loom—The loom of the future.

Noel Heaton, B.Sc., F.C.S., "Materials and Methods of Decorative Painting." Three Lectures.

March 18, 25, April 1.

Howard Lectures.

Monday evenings, at 8 o'clock :—

Captain H. R. Sankey, R.E., M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

April 29, May 6, 13, 20.

Dates to be hereafter announced :—

Charles C. Allom, "The Development of Artistic Skill in the Applied Arts."

Ernest Kilburn Scott, Assoc.M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere."

E. D. Morel, "British Rule in Nigeria."

Gordon Craig, "Art of the Theatre." Miss Ellen Terry will preside.

George Fletcher, "Technical Education in Ireland."

William Burton, M.A., F.C.S., "Ancient Egyptian Ceramics."

MEETINGS FOR THE ENSUING WEEK.

Monday, February 26...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Luther Hooper, "The Loom and Spindle : Past, Present and Future." (Lecture I.—Primitive weaving appliances—Prehistoric, ancient and modern.)

Farmers' Club, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mr. J. Sadler, "Milk Standards."

Post Office Electrical Engineers, Institution of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 5 p.m. Mr. B. O. Anson, "Machine Switching in Telephony."

Surveyors, 12, Great George-street, S.W., 5 p.m. Mr. L. S. Wood, "The Tendency towards Uniformity in Compensation for Agricultural Improvements."

Geographical, Burlington-gardens, W., 8.30 p.m. Mr. A. J. Sargent, "The Economic Geography of the Tyne."

Sanitary Engineers, Institute of, Caxton Hall, Westminster, S.W., 8 p.m. Professor Henry Adams, "Sanitary Building Construction."

Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Mr. F. C. Eden, "Hopes and Fears for Architecture."

Tuesday, February 27...Sociological, at the Royal Society of Arts, John-st., Adelphi, W.C., 8.15 p.m. Mr. W. T. Layton, "Economic Effects of the Rise in Prices."

Royal Institution, Albemarle-street, W., 3 p.m. Professor E. G. Coker, "Optical Determination of Stress, and some applications to Engineering Problems." (Lecture I.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on Mr. F. Shelford's paper, "Some Features of the West African Government Railways." 2. Professor John Goodman, "Roller and Ball Bearings," and "The Testing of Anti-Friction Bearing Metals."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Ven. Archdeacon Barnett, "Hong-Kong's part in China's Reform."

Optical Society, in the Rooms of the Chemical Society, Burlington House, W., 8 p.m. Annual Meeting.

Wednesday, February 28...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. H. A. Roberts, "Education in Science as a Preparation for Industrial Work."

Geological, Burlington House, W., 8 p.m. 1. Mr. L. J. Wills, "Late Glacial and post-Glacial Changes in the Lower Dee Valley." 2. Messrs. E. B. Bailey and M. Macgregor, "The Glen Orchy Anticline (Argyllshire)."

King's College, Strand, W.C., 5 p.m. (Lectures on Christian Art.) Mr. O. M. Dalton, "Minor Christian Arts."

Imperial Mission, Caxton Hall, Westminster, S.W., 8 p.m. Mr. C. Bright, "Inter-Imperial Cable Communications : A Non-party Question."

Royal Society of Literature, 20, Hanover-square, W., 5 p.m. Mr. C. E. Wade, "Nicholas Amhurst (1697–1742)."

Thursday, February 29...Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Child Study, 90, Buckingham Palace-road, S.W., 7.30 p.m. Mr. W. H. Winch, "Inductive *versus* Deductive Methods of Teaching : an Experimental Research."

Royal Institution, Albemarle-st, W., 3 p.m. Professor C. Oman, "Wellington's Army." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. H. E. Corke, "Wild Flowers."

Friday, March 1...Fine Art Trade Guild, at the Royal Society of Arts, John-street, Adelphi, W.C., 7 p.m. Lecture on "Engraving."

Royal Institution, Albemarle-street, W., 9 p.m. Dr. W. J. S. Lockyer, "The Total Solar Eclipse in the South Pacific, April, 1911."

African Society, Connaught Rooms, Great Queen-street, W.C., 8 p.m. Major E. A. Stanton, "The Anglo-Egyptian Sudan."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. H. J. F. Gourley, "The Design and Construction of Masonry Dams."

Saturday, March 2...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Molecular Physics." (Lecture II.)

Correction.—Mr. Cecil Thomas desires that the following correction be made in his paper on "Gem Engraving," published in the *Journal* of the 16th inst.:—On p. 364, col. 2, ll. 22, 23, delete the words "once belonging to Lotharius."

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,093. VOL. LX.

FRIDAY, MARCH 1, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 4th, 8 p.m. (Cantor Lecture.) LUTHER HOOPER, "The Loom and Spindle: Past, Present, and Future." (Lecture II.)

WEDNESDAY, MARCH 6th, 8 p.m. (Ordinary Meeting.) T. THORNE BAKER, "Some Modern Problems of Illumination: The Measurement and Comparison of Light Sources." JAMES SWINBURNE, F.R.S., will preside.

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, February 26th, MR. LUTHER HOOPER delivered the first lecture of his course on "The Loom and Spindle: Past, Present, and Future."

The lectures will be published in the *Journal* during the summer recess.

PROCEEDINGS OF THE SOCIETY.

TWELFTH ORDINARY MEETING.

Wednesday, February 28th, 1912; SIR HENRY A. MIERS, M.A., D.Sc., F.R.S., Principal of the University of London, in the chair.

The following candidates were proposed for election as members of the Society:—

Armstrong, Donald, Lieutenant (U.S. Army), Fort Williams, Maine, U.S.A.

Armstrong, Francis Tuttle, 565, West 113th-street, New York City, New York, U.S.A.

Engineer, Dhunjibhoy Temulji, Grant-road, Bombay, India.

Frere, Miss C. F., 67, Westbourne-terrace, W.

Gaye, William Charles, H.H. the Nizam's Guaranteed State Railway, Secunderabad, Deccan, India.

Mohammad, Professor Khwaja Dil, M.A., Islamia College, Lahore, India.

Napier, Robert West, 26, Bruntsfield-place, Edinburgh.

Pillow, Mrs. Margaret Eleanor, "The Grange," Thorpe-road, Norwich.

Tok, Maung Po, Tharrawaddy, Burma.

Traill, George, "Colwyn," Redington-road, West Heath, Hampstead, N.W.

Worth, Joseph Henry, Tongku, North China.

The following candidates were balloted for and duly elected members of the Society:—

Brown, Frank Percival, A.R.C.A., Halford House, Richmond, Surrey.

Buckley, John, "Arncliffe," Chartfield-avenue, Putney, S.W.

Hayward, Miss Florence, 4937, McPherson-avenue, St. Louis, Missouri, U.S.A.

Higgs, Arthur King, 95, High-street, Cheltenham.

Jhalawar, His Highness the Raj Rana of (Sir Bhawani Singh, K.C.S.I.), Kothi-gardens, Jhalrapatan, Rajputana, India.

Wakefield, Captain Edward William, Strickland-gate House, Kendal, Westmoreland.

The paper read was—

EDUCATION IN SCIENCE AS A PREPARATION FOR INDUSTRIAL WORK.

By H. A. ROBERTS, M.A.,

Secretary to the University of Cambridge Appointments Board.

I have had some difficulty in choosing a name for this paper. There has been much recent discussion of this and kindred matters, but this discussion has been confined, as a rule, to the question of the training and employment of industrial chemists or of engineers. I desire to survey a somewhat wider field; to inquire into the attitude of the industrial world to the educated man; into the question of the supply of persons of a high rank of intelligence; and into the effect of higher education, and particularly of education in science, on a young man's fitness for industrial purposes.

Hosted by Google

Incidentally, questions relating to the industrial chemist and the engineer, and to the condition of their earlier employment, will appear. The question, too, of how far academic ability is an earnest of success in practical life will inevitably be raised.

The class of students under consideration is of a somewhat high order of ability, and the question at once arises as to the numbers in which they are produced. Are there enough of them? Every practical man and every professor will tell you, No. Not enough, at all events, to meet the almost overwhelming demands of a great industrial community of the present day. Can we, then, increase the supply by means, for example, of the scholarship ladder? A Mendelian with whom I discussed this question was inclined to pessimism. "We are all such mongrels now," he said; and he was inclined to believe that society as a whole, in this country, had been so shaken, sifted, and sorted, that there was little chance of new combinations coming to light. He thought, however, that it was possible that some good old stocks, which had sunk to apparent decay in the devitalising circumstances of town life, might be really unimpaired, and under proper conditions might again be productive of ability. If that is so, the future becomes immensely more hopeful. The determination of this and kindred questions is urgent, and it is the imperative duty of students of genetics to endeavour to give us a clear lead.

Whatever be the truth, it is now demonstrated that there does exist a certain reserve of ability in those strata of society in which economic opportunity has as yet been scarce. Such evidence as is available at present suggests that this reserve is not nearly so great as popular imagination figures it. For example, the profitable expenditure of scholarship money, whether from old endowments or from the rates, undoubtedly has a limit which we appear to have reached and even overstepped. Experience may improve the methods of selection, and so increase the supply of good material. But it is important to administer the available funds wisely, and to give the really able a full measure of help, at the expense of those whose training will be less profitable to the community. I would further plead that a good store of physical energy is of the utmost importance for students of this type; the strain they have to undergo is heavy. How far the higher equipment should be carried is, even from the point of view of the student, a nice question. The years spent in attempting to acquire technical knowledge which is beyond the real limit of his ability may be positively harmful to him. For it must be remembered that on rather lower levels it is easier to achieve a relative success. To aim high is to incur risks; they are not *always* worth taking.

I will illustrate my meaning by some remarks made by a man of business who is also a man of science. He was discussing with me the question of employing the university-trained chemist. "It," said he, "I take a boy from a technical school, he is mere hands to me. If he is unsatisfactory or untrustworthy, I can dismiss him, and no one else will have him for similar purposes. If he is a good boy, he will finally arrive at a stipend not very different from that at which a university man would expect to start, and it will satisfy him. If he is a *very* good boy, he may attain £400 or £500 a year, or more, and a position of considerable responsibility. He will not then be so good as a man of better brains and wider training, but he will be a very effective man, all the same."

The explanation of the employment of the graduate in commerce may be put in a very few words. It arises from the tendency to the formation of great organisations and the use of capital in the mass. We have commenced the era of "Trusts" in some form or another. The old family business, small enough to be officered by a few sons and nephews, no longer occupies the whole field. In the great organisations there is room for the educated man, as a servant, it is true, but as a servant profitable both to himself and his employers. A friend of mine was asked by the parent of an able young graduate: "What guarantee have I that if my son comes to you, and is fitted for your purpose, he will receive his deserts?" The answer was: "We have a vast capital invested; we must earn our dividends. To do so we must have the best ability we can command, and it is to our interest to pay well to retain it." Moreover, even in the family businesses, sons and nephews do not among themselves always run to the necessary ability or industry, or there are not enough of them. In any case, it is the undoubted fact that these businesses are tending no longer to breed in, but to ask for new blood. I used to hear the objection: "But how shall I take a man into my business, a stranger to me, and recommended by strangers to me?" I think that by careful and responsible recommendation we are in a fair way to overcome that undoubted difficulty.

Hosted by Google

Modern business, moreover, is said to require more imagination, more adaptability, and a wider outlook than was once the case. More than one business man has been critical in my hearing of the traditional view that the only way to become a practical man of affairs is to enter an office early in life, at fifteen or at latest sixteen, and has pointed out that the best years of growth of the mind and of the imagination are thus devoted to routine alone. Is this not too greatly to glorify routine, even business routine, and to regard its attainment as a dark mystery—a *hocus pocus* beyond the grasp of a man of good intelligence at the age of twenty-two? There is another point, too. Many City houses take their employees—I mean those who will, in the course of things, occupy reasonably good positions—from the great London schools at the age of eighteen or nineteen. By so doing they cut out automatically the boys of best ability. There are, I am aware, great difficulties in the way of introducing them at a later stage, but they are difficulties which it is important to overcome.

Anyhow, the tendency to the employment of the more highly educated man is there. In a paper which I read before the British Association in 1904, I pointed out the growing diversity of employment of graduates, and I stated, as the result of examination of the records of a particular college, that in 1865–70, only 3·3 per cent. of graduates adopted a commercial life; in 1885–90 this percentage had risen to 11·5; while of the students matriculating in 1900 and 1901 no fewer than 21 per cent. were destined for commerce on either its administrative or technical side. This drift and its significance was clearly apprehended by the far-sighted men of eminence, in the university or the world of affairs, who gave us our Appointments Board in 1902.

Further, an undoubted change of feeling is taking place towards what must, after all, be the chief concern of an industrial community. I am still sometimes depressed when I tell the head-master of a public school that a favourite pupil has gone into the service of a great commercial house, and he replies, "I hoped he was destined for a more distinguished career"; or when a professional parent tells me that his son will be wasted in business, since (astounding statement) "Anyone can make money." I would earnestly plead for some attention on the part of educators to the ethics of earning an adequate income.

Hazlitt satirically depicts what I may call the nineteenth century attitude:—

"*On the Disadvantages of Intellectual Superiority.*—It is astonishing how soon a fellow without education will learn to cheat. He is impervious to any ray of liberal knowledge: his understanding is 'not pierceable by power of any star,' but it is porous to all sorts of tricks, chicanery, stratagems, and knavery by which anything can be got. . . . I think it is a rule that men in business should not be taught other things. Anyone will be almost sure to make money who has no other idea in his head. A college education or intense study of abstract truth will not enable a man to drive a bargain, to overreach another, or even to guard himself from being overreached. As Shakespeare says that 'to have a good face is the effect of study, but reading and writing come by nature,' so it might be argued that to be a knave is the gift of fortune, but to play the fool to advantage it is necessary to be a learned man. Many a man has been hindered from pushing his fortune in the world by an early cultivation of his moral sense, and has repented of it at leisure during the rest of his life. A shrewd man said of my father, that he would not send a son of his to school to him on any account, for that by teaching him to speak the truth, he would disqualify him from getting his living in the world!"

Contrast this with Lecky's finely expressed view ("History of European Morals," Vol. I. pp. 137–8. Longmans, 1902) that veracity is the special virtue of an industrial nation, and, indeed, constitutes the chief moral superiority of nations pervaded by a strong industrial spirit. To illustrate the new attitude, I will quote from a lecture recently given at Cambridge by the managing director of a great manufacturing business:—

"Cambridge has trained for the nation a large share of her statesmen, her thinkers, her historians, her teachers, her military and civic leaders; and it is from no lack of appreciation, either of these things or of the contemplative life which is fostered here, that I refer to another avenue of effective life. I feel so sure that industrial affairs also have a large influence upon the progress of the race and the nation that I call for the aid of educated men.

"The door does not lead to a field of assured success, but as a rule it has rich rewards both for men with and without capital, varying according to the power and fitness of the individual. It does not present a satisfactory opening for those who have no capacity to work with other men, nor for those who do not enjoy dealing with life in all its forms. It carries with it an infinite variety of occupation, a chance to pursue and develop scientific thoughts.

"I have not, as a rule, found that the men who interest me are absorbed in the idea of making money for themselves. The remuneration is simply a useful detail. Their minds run in rather an undefined way toward playing the game successfully.

"I can only indicate briefly some of the

Hosted by Google

opportunities for a wholesome life in the field under review:—

"An intimate touch with the life of plain people.

"Contact with the grind and sweat of labour.

"A study of the skilful and of the dull worker.

"A frank understanding of the problems faced by a workman's family on an inadequate income.

"Dealing generally with the hopefulness of youth, tempered by the squalor of the improvident.

"Lending a hand in creating work for labour that otherwise will slip away and become unfit for any employment."

I come now to the question of a scientific education as a preparation for affairs. "Science" has been so frequently advocated as an educational panacea that it is as well to examine how far the facts justify this. Perhaps it will lead to clear expression if I state my own conclusions. Number 2 has been arrived at in contradiction to my own previous prejudice. They are:—

(1) That the essential of education for practical affairs is that it should not be an education of "snippets," but should proceed along one main line. A young man should have a "file to bite."

(2) That so far as general affairs are concerned —those which require no special technical knowledge—the scientific education, carried far enough, is as good as any other, but does not appear to be better. But that a minimum of science should be included in every education. This minimum should be something more than that indicated by a late headmaster of a great public school, who wanted his boys taught "as much science as a gentleman ought to know."

(3) That there is, nevertheless, a vast area of possible employment in industry for which a scientific education is *essential*, and that therefore the boy who receives, and is fitted for, a scientific education has exceptional opportunities.

We are making no attempt to decide on broad lines the educational courses in our secondary schools; we merely introduce more subjects in response to popular clamour. Yet we are spending millions on equipment on no considered plan. Provided the machines and buildings are large enough, or expensive enough, and run enough energy to waste each day, we are satisfied. Yet this question of curricula, as every teacher knows, cries for solution; and the schoolmaster, the very man who knows the properties of his raw material, will certainly not have much say in the solution of it. While large sums are lavished on buildings and plant, we keep the pay of our teachers at a level which is absolutely scandalous. I think that if all governing bodies, all State officials concerned, and all benefactors to education, had so much knowledge of science as would enable them, say, to understand what they read in the daily press, or the general drift of a lawsuit in which a scientific question is involved, we should be able to write on the walls of our schools and universities, "Men, not bricks and mortar" I turn to another aspect of the same question. It has been well said that "the ignorant always believe in the false prophet." A man of business ought to be able to form some judgment, from his own knowledge, of the qualifications of any "expert" appointed by him. I have in mind a recent instance in which a mistake made in such a matter is likely to prove disastrous. The right advice was, in this case, particularly easy to get, as there are two or three men whose names and work are well known, any one of whom could have helped the firm in question to make a suitable choice.

I will now deal with my second conclusion. A combination-room story, at my expense, states that I received a telegram in the following words: "Please send traffic officer at once; classic or moral science man preferred." The story, though not accurate, was well founded. I had received a long letter very much to that effect. It is interesting to study the kind of degree taken by about fifty Cambridge men employed in commerce by five or six great organisations. The men are nearly all well under thirty years of age.

I have included in the list every graduate known to me as employed in the houses concerned, in order to avoid any suggestion of selection. 19 graduated in classics, 5 in history, 5 in law, 1 in theology, 4 in modern languages, 8 in mathematics, 5 in engineering, and 8 in natural sciences. They were 52 in all, four of them graduating in more than one subject. The classical ability shows up extremely well, but it must be remembered, in counting heads, that graduates in science have, as a rule, more specialised careers in view.*

Now, this is a peculiarly efficient group of men for their purpose. Two of them only, after a trial, thought themselves unfit for commercial work; a number, with good fortune, it is true, are already occupying positions of high responsibility. Here, then, is an interesting means of considering whether academic ability has any relation to ability for affairs. Speaking generally, the men were chosen with the highest degrees that could be got, consistent with

* It should be observed that the supply of material in law and modern languages is also limited. The degree in theology is, of course, an accident.

Hosted by Google

a good manner, a good physique, a certain abundant energy and versatility, as shown by their other interests besides their "work." They were also known to have got on well with their fellows. All these latter qualities were important, but it is believed by experience of these and other cases, covering a fairly wide field, that the factor of academic ability is also important; and, in fact, forty-four of the men fall academically into the First Class or the upper part of the Second. The exceptions are mainly mathematical or engineering students, but the extremely keen competition in these subjects at Cambridge may account for this. It will be seen that this result is in accord with the analysis made at the Galton Laboratory of the class lists in *Literae humaniores* at Oxford, which proves (I quote from memory) that the successful in after-life were mainly distributed over the First and Second Classes, with a slight, but not an overwhelming, preponderance in favour of the first; the proportion of successful men in the lower classes was much less. The careers were, however, as was to be expected from the dates of the class lists, mainly professional.

But an education in science leads to wide opportunities. There is not only the general world of affairs, now to some extent open at university age to a boy of ability, whatever his training may be, literary or scientific, but there is the whole field of technical industry, engineering, and agriculture; there are the scientific departments in India, in some self-governing colonies, in the Crown colonies, and other possibilities too long to enumerate. Yet I cannot satisfy myself that the outcome of the scientific education is at present all it should be; indeed, I think I detect many a case of undeveloped ability, a want of power of expression, above all, which points to a serious defect. The public schools do not turn out enough students of science. The others turn out many, but they seem to be specialised much too early; they are good examinees. I believe that those of real originality suffer less under the system than the rest. But it is given to few of us to be original. If these boys had a reasonable literary bias, and in consequence could think clearly and express themselves clearly in terms of their mother tongue at least, they might be very effective material for the world's purposes. But they are apt to be diffident and tongue-tied, or if not unsure, then too sure of themselves. Both types are common, and they are associated in my mind with the question and answer: "Do you write a fair English essay?" "Ah, I am afraid that is my weak point." I do not think that a training in English would be sufficient in itself; there ought to be an adequate study of at least one difficult foreign language.

Here is a rather brilliant little group of twelve young Cambridge men employed in technical industry. All are, as far as I can tell, likely to rise to considerable distinction. I have chosen them as being employed on the administrative rather than the technical side. It will be observed that eight are First Class men, two graduated in the Second Class, and two in the Third. Their scientific qualifications are about equally divided between pure science and engineering. In several cases there is strongly marked literary power. Of the others, all with one exception have had a good literary basis to their education; for they come either from public schools in which a high literary standard is set, or from a few other large schools of which the same is true. I call to mind two or three other cases in which the ability as recorded by academic performance is equal to the best shown above, and in which there was no fault to find with character; but in some indefinite way the men did not seem broad enough for a career of organisation, and, looking at the early records, I have suspected that the chemical laboratory replaced the Latin grammar at too early a stage.

I now come to the question of the training of young men who aim definitely at a career on the technical, as opposed to the administrative, side of industry. In a general way, the sound opinion seems fortunately to be gaining ground with rapidity. It is that, whatever else is omitted, the training in pure science should be as complete as possible, and that it certainly is not complete without a reasonable amount of research. The latter is especially valuable in developing manipulative skill and self-reliance, and I am inclined to attach the greatest importance to the research period. This, of course, involves a university course of four and, if possible, five years. It is therefore most desirable that the "assisted" student should not have his university career cut too short. If, in consequence, the less able students find their way to the more strictly technical schools, they will actually profit in the long run. Here they will prove capable students, and will become valuable parts of the industrial machine, satisfactory to themselves and to others. The grading of ability is thus of supreme importance. The advantage of examination records for public purposes, or for those who are disposing of public funds, is

Hosted by Google

that they are absolutely impartial. That is the reason why, in spite of the acknowledged imperfection of the system, it is difficult to displace. But in the determining of how far a given student should be encouraged and assisted to proceed, it is, I think, most desirable that the opinions of the professors, and others who know best the quality of his mind, should be taken into account.

After a five years' course in a university, the student may have reached the age of twenty-three or twenty-four without having as yet earned a penny. That state of things has not unnaturally evoked criticism, and there have been attempts in high quarters to reduce the age at which a boy enters the university. May I state how I think the matter stands? In the first place you have the almost unanimous opinion of university authorities, that in point of age and mental capacity the earliest profitable age for entry is about eighteen. It may be that boys are at an earlier stage not sufficiently hardened to go through what is, in the case of the industrious student, a very strenuous college course. The relative tenderness of boys at the earlier age, or at least their want of the necessary development fully to profit by their work, is certainly borne in on me at the Appointments Board. I find that, judging by collateral evidence of capacity, a man entering at the earlier age usually graduates in a class at least one, sometimes two, lower than he should; and this is a severe handicap to him in starting his career.

In considering, too, the age at which a man may be supposed to begin work of the highest technical kind, we may compare our own practice with that of our two greatest industrial rivals—Germany and the United States. In these nations the training is considerably longer, and is seldom finished before twenty-seven or twenty-eight, very much as is the case with us in medicine. Here, at least, is an American statement:—"I told my son, when he started in his profession at the age of twenty-nine, after a long training, that he represented an investment of £6,000." It is certainly possible to go on too long, and I know of students who by doing so have missed their market. But I suggest that at the age of twenty-three or twenty-four we have arrived at what is, in our own experience, the ideal age for undertaking the strenuous and taxing work of industrial chemistry.

The catalogue of "what every industrial chemist ought to know" is truly formidable. Here is a list, taken from a discussion published in the *Journal of The Society of Chemical Industry**:—French and German; mathematics, at least up to the elements of the differential and integral calculus; a complete course of laboratory work in inorganic, analytical, physical and organic chemistry; physics; a knowledge of fuel and fuel economy, steam-raising plant, steam-engines, gas-producers, gas and oil engines, electrical generators and motors; water purification, and metallurgy; furnace construction, the general principles of machinery and engineering drawing; business methods and costs of all kinds; economics; a knowledge in particular of the chemical markets, and a knowledge of all the important printed research on his subject. As to the last, of course, the really important thing is to teach the student where and how to look for his knowledge, and, above all, how to judge of its importance. It is obvious that all this knowledge cannot be acquired in four or five years, and we must be grateful that it is being widely recognised that the man who will make the best industrial chemist will be he who makes the most of what a university has to give him, rather than he who spends time at this stage on matters which should really be learnt in the works. I feel sure that academic makeshifts for works experience will ultimately be recognised as unsatisfactory.

This view must of necessity be true of the knowledge of costs. Mr. Blair, in an able paper, containing much valuable matter, read before the British Association at Sheffield, quotes a "college" authority as saying:—"I consider the question of cost in design, and the commercial side generally, receives quite adequate attention in most colleges." The training is, of course, of the utmost importance, but surely the "college" is not the place for it. Swift, in his bitter attack on men of science, shows one of the professors in the Academy of Laputa endeavouring to extract sunbeams from cucumbers. It is an unfortunate instance of satire which has missed its point. The good man was only born two hundred years too soon; he was clearly interested in "reversible processes." But would there be any faculty more worthy of inclusion in Swift's academy than a faculty of "chemical costing"? Imagine a "costs room" in a chemical or engineering laboratory where all the bases are theoretical, where there are no real economic data, where there is no real industrial pressure, where, in short, everything is in the air!

So much, then, for the university, or the technical high school of approximately university

* Vol. XXVIII. No. 6.

Hosted by Google

rank. How about the technical schools as a preparation for industrial work? They aim, of course, at educating a different order of student. Are their methods in all respects satisfactory? I have had the curiosity to measure the plans of one of them, a school most lavishly equipped. The space allotted to pure science and engineering was about 40 per cent. of the whole. This space, however, included *all* the lecture-room accommodation, and the professors' and students' rooms. The remaining 60 per cent. of space was allotted to the purely technical processes, such as dyeing, weaving, brewing, etc.

The space allotted to pure chemistry was 3½ per cent. of the whole; that allotted to physics was less. Now, in view of the importance of an elementary knowledge of chemistry in all the work undertaken, of the importance of an advanced knowledge in much, and of a superlative knowledge in the case of some students, the space allotted to pure chemistry is ludicrously small. Either the professors and lecturers must be worked off their heads by duplication of courses or the knowledge of chemistry acquired by the students (there is, fortunately, no question of the skill or eminence of the staff) must be extremely rudimentary; probably both statements are true. In any case, the proportion points to a want of appreciation of the value of pure science on the part of those originally responsible. The ideal of a technical industrial process is that it should be automatic, and all good processes tend to become so; a working knowledge of them is, therefore, much easier to acquire than a knowledge of the science, which is hard. A student tends to follow the line of least resistance; and as he deals in the works in any case with an automatic process, his final equipment is apt to be unsatisfactory and disappointing. I am told that some technical schools have really done a great deal of harm in this way.

For want of space and of exact figures, I must leave aside the question of how it will be possible to renew these large plants; when they are out of date they will become positively harmful. And is it seriously proposed to spend on the equipment of these schools a quarter or half a million every fifteen years or so? I cannot but think that the money could be better used, even if it could be found.

One last word on this matter. There has been much discussion of the question of working in bulk. Well, in every large and well-appointed laboratory work is frequently done on the cwt. scale; is the ton scale any better, really, for students? Or is there not quite as much transition from the gramme scale to the cwt. scale as from the ton to the twenty or fifty ton? I read of the miserable spectacle of "squads of students" watching the process in "miniature bulk" go through. They cannot all handle the process, and to be mere bystanders is apt to be a waste of time. In any case, the transference of a particular process from the laboratory to the works stage must be a delicate matter, individual for each process, and essentially a matter for experience in the works.

I come now to the question of supply and demand. I am told by good authorities that a great deal of the criticism levelled at the English industrial world on the subject of its neglect of chemistry is very much beside the mark. Take the often quoted case of the aniline industry. The real reason of its leaving the country is hardly fairly presented. The Prince Consort's foresight led him to bring A. W. von Hofmann to London, and the latter was given the opportunity of organising the College of Chemistry in Oxford Street, which developed into the Royal College of Science. The Prince Consort's death was the real disaster. Hofmann and the German colleagues whom he had introduced lost their natural protector and patron. Hofmann was soon attracted back to Berlin. His companions followed him, and naturally took much of the skilled knowledge of the newly-founded industry with them. In a few years Germany had the chief outlines of the coal-tar colour industry mapped out in its patent literature. With the start thus acquired, it was almost impossible that a competition of a serious character could come from this country. The case of the coal-tar dyes is frequently quoted against us. But while our imports of these from Germany are worth £1,683,000, we have, on the other side, immense exports of rough inorganic chemicals to that country. A Cambridge man in business in the Midlands tells the same tale. "I can assure you that, whatever may be the case in other parts of the country, the manufacturers in my neighbourhood are fully alive to the importance of science."

I may be asked, then, are we at Cambridge satisfied with the attitude of manufacturers? The answer is, broadly, Yes. We could fill more good places than we have men for, and I am very much relieved, where I should have been anxious a few years ago, to know that the number of students reading advanced chemistry at Cambridge has precisely doubled

Hosted by Google

in this last year. It is gratifying, too, to find great concerns giving us a general order to report whenever we have ready a man who is likely to satisfy their requirements.

A general idea of what happens to those who specialise in chemistry may be enlightening. Dealing with a small compact body of men of this kind, of course it is extremely important to avoid any kind of identification. I have not, therefore, taken a particular year; but have proceeded on an automatic principle which has left nothing to judgment in the way of selection in order that classes of the more and the less successful might be represented. The method adopted necessarily involves the inclusion of one or two men whose destinations are not finally settled; but there is no reasonable doubt that they are allocated to the right classes. Their destination appears to be as follows: 13 per cent. are or will be ultimately teachers or researchers of the highest rank; 15 per cent. will be occupied in public schools and important technical schools; 58 per cent. will be employed in industry, either as chemists or managers—a few of these will be in their fathers' businesses; about 5 per cent may be absorbed by agricultural research; as to the remaining 10 per cent. I can give no information.

In speaking of these men it must be remembered that, though they ultimately specialise in chemistry, our Cambridge system insists on a wider training in the early part of their career in several branches of natural science, such as physics, geology, and botany, and, as a rule, three subjects are taken in the earlier years. In some respects it is possible that the present system might be improved; there is a tendency to devote more time to research and less to the formal examination, and probably it should be more easy than it is to spend a little time in the engineering laboratories, just as the engineers often do some chemistry.

In order not to rely entirely on our own impressions, I have examined the output of one of the higher technical colleges where a diploma of associate in chemistry is given, and where the work reaches a high standard. During eighteen years they turned out on an average four or five chemists a year of the requisite standard. There were ninety candidates who obtained the diploma in all. During the first period there were between three and four a year, and during the second part of the period between six and seven. Men of this order of ability in chemistry are produced in relatively small quantities, and I do not think that the output is at all unsatisfactory. The associates are younger than our graduates, and are not so widely trained. But they acquire a good knowledge of chemistry, and the school has produced some eminent men.

The data work out as follows: The number of associates employed in technical industry is 64 per cent. I do not know the nature of the career in the case of all the employing firms; but I happen to know that some of the careers are very good. The higher branches of teaching absorb 10 per cent. These are professors in this country or at colonial universities; 10 per cent. are consulting chemists or analysts. The Government service has taken 6 per cent. Another 6 per cent. are in schools—in the last two categories there are several women—and, finally, 3 per cent. are unclassified. Of the latter some did not definitely follow a chemical career. I think this must be regarded as a most satisfactory result, and one on which the school in question may be highly congratulated. When it is considered that not every man who reaches the necessary scientific standard is fitted to engage in business, the wastage here is really very small, and the careers of the 14 or 15 per cent. who are not engaged in technical chemistry in some form or other appear to be satisfactory ones; in fact, I believe, that dissatisfaction, so far as it exists, comes mostly from the unfit.

Now, though the conditions of employment in the case of the more highly trained men, as shown above, are satisfactory, there are two points to which I should like to allude:—

(1) Commencing stipends are often all that can be desired, and some firms show a generous appreciation of the fact that, though a man cannot be immediately useful, still a large sum has been spent on his education, and he cannot be expected to look with any satisfaction on the offer of work at a salary which is temporarily small. I think the conditions in the first year or two should be laid down rather more definitely than is sometimes the case, and that a little more liberality in this respect would do something to increase the number of men who adopt technical chemistry as a career. I do not think that the initial salary should be so much as to debar satisfaction at subsequent and fairly immediate increases, but I believe that an initial contract which gave a relatively small pay for six months, say, at the rate of between £100 or £150 a year, and after that a guarantee, in the case of satisfaction, of a commencing stipend of £200, would be found to be satisfactory.

(2) There is another point. I am not so wel

Hosted by Google

satisfied with the prospects of employment for a rather different class of man as a process conductor, a man who might rise to be a useful business man, either in the works or in other parts of the administration. Such a man, while giving evidence of good ability, say, in Part I of the Natural Sciences Tripos, would be chosen very largely on personal characteristics. He would be very much like the class of man engaged in business administration to which I have alluded in the first part of my paper. He would, above all, be a cheerful person in himself and capable of getting work in a cheerful way out of others. I have in mind a little homogeneous group of four or five men in the employment of one firm, who exactly fit the situation; and I feel, therefore, that there ought to be a wide ground in industry for the profitable employment of such men.

It is just possible that if English contracts with technical men were a little less stringent, the tendency of good men to seek a career in commercial chemistry might be somewhat increased. I give no dogmatic opinion. I know the great difficulty of the problem, and there is certainly a tendency to make contracts much more stringent than formerly. Cases of breach of contract appear to be very seldom brought into court, and I am told that it is exceedingly difficult to say what contract is good in law, and what is not; the courts will decide each separate case on the ground of what appears to be reasonable. I am sure British manufacturers have considered their ground most carefully, and it would be a mistake to desire any change which would harm British industry or make it more difficult than it is at present for a scientifically trained man to find a reasonable place in it. I had, however, the curiosity to inquire what was the practice in Germany with regard to contracts, and through the kindness of a friend I have been informed of the general nature of German contracts.

My friend has had in the past a most successful experience as a manufacturer, and it is to be noticed that he takes a sympathetic view of the considerable protection which the German law affords the employee. "Contracts," he said, "which bind a scientific assistant for so long a period as you suggest have fortunately long been given up in Germany. Our legislature, and still more our courts, take a strong line in favour of the economically weaker person." In the case of commercial employees, no contract which places an unreasonable hindrance in the way of the success of the employee is binding, and on no account whatever can any restrictive conditions apply after three years from the termination of the contract. Scientific assistants do not, however, come under the commercial law. The professional law protects them against exploitation by industry, but not so clearly as the commercial law does those to whom it applies. Hence a constant agitation by them for a protection similar to that given to the purely commercial man.

A common form of contract for the scientific assistant would not appear to be very different from the English, except that its restrictive clauses would be less severe. For instance, the chemist might be bound for a very short period not to enter into or create a similar business, but if, within that period, an offer of that kind is made to him, then he would have the right to compensation in view of his refusal. He might also be bound to secrecy for three or four years. A quite recent decision of the Supreme Court carries the matter still further, at least in the case, apparently, of the commercial employee. According to this decision all secrets which he may have acquired in the course of his business, scientific or otherwise, are part of his fair economic equipment, and he may turn them to account directly his contract ceases, provided he has acquired them in the normal and proper exercise of his employment, and not by sharp practice. Should there be an improper use made of them, it is against the new *employer* that the remedy lies. If secrets are betrayed by an employee before his engagement terminates, both he who betrays the secret and he who uses it are liable to a penalty. The liberal tendency of the German law can hardly be out of sympathy with general opinion. But its importance could not be properly estimated without ascertaining the opinion of German manufacturers, and that would be difficult to do. Whichever tendency is right, the German or the British, it is clear that the employer should do his best to ascertain the entire trustworthiness of the man whom he engages.

It must not be supposed that the industrial chemist is the only type of graduate for whom there is a demand. Agriculture has just awakened to the fact that the scientifically trained man can be of the greatest use. Until twenty years or so ago, the only science which had really established any definite claim to assist agriculture was chemistry. Even then every country, every colony, every agricultural society had its trained chemist. But in those days the chemist largely confined his attention to analysing manures, foods, and other agricultural commodities.

All this is now changed. There are still

Hosted by Google

analysts who perform the invaluable function of controlling the sale of fertilisers and feeding stuffs, but agriculture is nowadays employing scientific chemists to investigate such subjects as the problems of soil fertility and the growth of crops, and the laws of nutrition of animals. Botany, too, has established itself as a valuable ally—not only in the routine work of seed-testing and such-like, but in the investigations of plant-breeding and disease resistance. The trained entomologist, the bacteriologist, and the geologist, are frequently called for.

In fact, at the present time, the demand for young men with a sound scientific training followed by a good training in one of the branches of agricultural science is greater than the supply. This demand will increase as the agricultural departments in India, Egypt, South Africa, and the West Indies, become more efficiently organised. The demand at home, too, must increase as new posts are created throughout the country under the stimulus of the Development Fund This is much to be desired, for agricultural education in England has been hindered by the fact that the salaries and prospects have been too poor to attract the best men.

The question of the employment and of the education of engineers is a good deal simpler. As regards education, a theoretical course is now generally admitted to be desirable. In this, a considerable handling of tools and machines is of course essential, and this accounts for the very large space occupied by the engineering department of the technical school I mentioned above. A student even in the drawing office wants a good deal of room. In the case of engineering laboratories, however, there seems to be a tendency to unnecessary size of machinery, with all the attendant expenses of energy running to waste, more lighting, heating, higher rent and rates. Besides, apart from the mistake of running a 200 horse-power engine when a 20 horse-power will do, you can, I presume, for the same current cost, run ten 20 horse-power engines at once. Now this is a great advantage, for, as a fact, it is a complaint of students who have learned in the laboratories equipped on the larger scale that they far too often have merely to look on idly when they wish to handle things for themselves.

Owing to the enlightened policy of many of the great firms of mechanical engineers, a student's practical training is nowadays easy to get. Premiums are the exception, and I know firms who will help out a student of more than average ability.

The general situation may be gathered from a paper issued by our Appointments Board in 1910. Sir William Mather suggested that we should make a census of our past engineering students, and he kindly drew up a report for the consideration of the Board, on which report this paper is based. Returns were obtained for 176 graduates, 133 of whom belonged to the years 1902–6. The average age of these was about twenty-eight. I quote from the paper :—

"The employment of the 176 graduates at the beginning of 1909 may be roughly classified as follows :—

1.	Directors or Partners in manufacturing concerns	10
2.	Partners in Consulting Engineering firms	14
3.	Subordinate positions in manufacturing firms (ranging from Draughtsman or Works-Manager's Assistant up to Works Manager)	49
4.	Assistants to Consulting Engineers	9
5.	Professors or Heads of Teaching Institutions	6
6.	Assistant Teachers	17
7.	In service of Government, Municipalities, or Railway Companies in the British Isles	12
8.	Government Engineering Services abroad	28
9.	Miscellaneous	31

"As was to be expected, no return of remuneration was furnished in most of the cases coming under headings 1 and 2, but where the graduate is a director or partner in a well-known firm, it may be surmised that the remuneration is satisfactory and probably much in excess of that earned by men in subordinate positions. In some cases the graduates in classes 1 and 2 had entered established businesses; in others, they had started concerns of their own—in several instances with marked success. The salaries of the men coming under heading 3 varied from £150 for the youngest up to about £500, the average being about £200. The salaries of those who were in the teaching profession varied from £170 to £1,000, the average being about £400. The salary of a man of twenty-nine employed in the Government Engineering Service in India would be about £460.

"These figures as to remuneration support the conclusion that until he is about thirty years of age a Cambridge graduate in engineering can earn considerably more as a teacher or in Government employment than if he enters the service of a private firm; on the other hand, the salaries of the higher officials in private firms are probably superior to those attached to positions of equal responsibility in Government or municipal services, and, of course, the remuneration of those in the highest places is very much greater. In the teaching profession also the pay is better at first,

Hosted by Google

but not so good in the long run, as in practical engineering work. The salaries of the twenty-three teachers referred to in this return, however, are probably above the average, because one-fourth of them are occupying well-paid posts as professors or heads of institutions, and many spent two or three years before or after graduation in acquiring practical experience, which is now an essential qualification for the better-paid posts of this character.

"Among those coming under the heading 'Miscellaneous' (No. 9 above) are seven barristers, four of whom are in active practice and the others in course of preparation, three journalists, two soldiers, two architects, one artist, a clergyman, and a missionary. Three are engaged in scientific research, two at the National Physical Laboratory, and the remainder in commercial pursuits of various kinds. It has been from the outset a guiding principle with those responsible for the conduct of the engineering school that the course of instruction there should not be inferior to the older studies of the University as a general training of the mind, useful to anyone whether he become an engineer or not. The considerable number of men who, after graduating in Engineering, have been successful in other walks of life, is some evidence that the policy of the school in this respect has attained its objects.

"A few remarks may be added as to the course followed by Cambridge graduates in the two years immediately after graduation. In the year 1908—which may be taken as typical—forty-three men graduated in the Mechanical Sciences Tripos, but of these only thirty obtained honours, the remaining thirteen being allowed the ordinary degree. The situations filled by these men at the beginning of 1909 are known in every case but two, and were as follows:—

1.	Premium Apprentices in Works	5
2.	Premium Pupils with Civil Engineers	5
3.	Pupils or Apprentices not paying a premium	13
4.	Salaried Posts (one teacher)	6
5.	Still at Cambridge	7
6.	Employment other than Engineering	2
7.	No employment (one ill)	3

"Of the seven men who appear under heading 5, as spending a fourth year at Cambridge, five were engaged in research at the Engineering Laboratory.

"It may be added that most Cambridge men come straight to the University from school, and get the whole of their practical experience after graduation. A small proportion, however, perhaps two or three per annum, have spent more or less time in works before entering the University. There is no evidence in the information summarised in this circular that this procedure is either better or worse than the other.

"In addition to those who enter for the Mechanical Sciences Tripos, from thirty to forty students per annum proceed to the ordinary degree by taking the Special Examination in Mechanism. This examination is easier than the Tripos, and adapted for men who have not much aptitude for mathematics. A common practice for such men is to enter for the Associate Membership Examination of the Institution of Civil Engineers, which they generally have very little difficulty in passing, a few months after graduation. They then go into works as apprentices, and follow much the same course as Honours men. While not equal to Honours men on the average in technical knowledge and ability, many of them have excellent business capacity and do well in practical life."

The situation with regard to civil engineers in this country is not by any means so satisfactory as is the case with those who go to the mechanical firms. In the first place the premium requisite for entry into a first-class firm is a very large one, and is prohibitive to many students. The remedy is not easy to see, for the pupil of a great civil engineer gets a very valuable training in return for his premium. But the fact remains that many of the abler men are excluded. In the second case, work in an old country is naturally scarce, and, thirdly, so much civil work is dependent on borrowed capital that a general rise in the rate of interest tends to prevent the execution of all but the barely necessary. Further, I seriously doubt whether the services of corporations, municipalities, etc., are recruited in a really satisfactory way. The Government services on the other hand, and those public enterprises abroad, the officering of which is entrusted to eminent civil engineers in this country, are well recruited. A few great railways take a very enlightened course, and do not allow premium pupils. In others, the premiums paid to the chief engineer are high, and it is moreover suggested in some cases that the better posts in the service are a close preserve; though why this should be, considering that the capital is that of the shareholders at large, it is difficult to say.

I have laid stress on training in pure science. Fortunately, nowadays, we are far from the attitude which held that directly a discovery became economically profitable the treatment of it should at once be excluded from any educational course. Yet that, or something like it, is an attitude which is, or has been held. But there are not two kinds of science, there is only one. Employed for purposes of production, a given line of research may not be worth carrying out, however fascinating it may be from the scientific point of view. And even in the cases in which a discovery is economically profitable a manufacturer may have to pigeonhole the patent for a long period; he may have already a more

Hosted by Google

costly process at work, involving an elaborate plant, and, unless he sees that he can put the product on the market with a sufficiently greater margin of profit to himself, he may not be justified in the new capital outlay. It is so easy to talk of "scrapping" plant. His attitude is not even necessarily anti-social; it may not be the best for the consumer at the moment; but if he is a good employer he may think of the large area over which he will have to disturb the conditions of employment of his own workmen. It is all the more important then that pure science as opposed to the creating of processes should be heavily endowed. The chemist or the biologist must be able to pursue investigations which are not immediately profitable. I may illustrate by the case of bio-chemistry. It is a science which lies at the root of the problem of plant and animal disease, plant and animal nutrition, and so is fundamental to medicine, to agriculture, to stock breeders and to the feeding of the classes who have not sufficient means to secure a "mixed diet." And in all these directions there are problems of the first magnitude awaiting solution. Yet the amount of research done in England has been very much less than it should have been, simply because the difficulty of the immediate steps in research has been realised, and there has not been a sufficient livelihood or equipment for those who were known to be fitted to overcome those difficulties. It is not by direct means only that science can serve industry.

DISCUSSION.

The Chairman (Sir Henry Miers) said the author had directed with conspicuous success during the last ten years the most successful of all the Appointment Boards in the British Isles, and in his paper had opened up many matters of importance to educational experts. There was no more important duty falling on the universities than that of fitting their students for the places they had to occupy in life, and there was no greater responsibility on employers of labour than to obtain the best material from all sources, universities and other educational institutions. One point to be borne in mind was that a residential university like Cambridge, in recommending students, had the very great advantage of being able to refer not only to the results of examinations, but to prolonged personal knowledge of the student, and he thought Mr. Roberts would be the first to confess that such recommendations were influenced as much from such personal knowledge as from the examination successes.

Mr. R. Blair (Education Officer, London County Council) said there was probably no man in England who had had so much experience in "marketing goods" of the peculiar kind which universities produced as the author. Educational institutions would do well to give far more attention to that matter than they had hitherto done, and to remember that a boy had to make his way in the world, and that some sort of provision should be made for that purpose. The Cambridge Appointments Board had done a great deal to show other authorities how the industrial and commercial world could be linked up to the university. It occurred to him that a subsidiary name for the paper might be "The Supply, the Training and the Placing of the First Class Man." Taking first the supply, he thought the country had a very much larger untapped supply amongst the population of the small towns and villages than was generally thought to be the case, a supply which the northern part of Great Britain had drawn on for some considerable time. It was perfectly clear that the First Class man must possess many qualifications, amongst which were strength of character and mental and physical strength. Often the poor man had a struggle at his secondary school and his university, a real physical struggle to keep his position in the university alongside of men who had been better housed and fed, and he also had the struggle of the examinations, and when entering, for instance, the Indian Civil Service, he had a further struggle in learning the Indian language, a struggle with the climate, and the final struggle some day of taking full responsibility. If he had not harboured his strength for that day it would not go well with him. That showed how difficult it was for the poor man to maintain his path with his physical strength unimpaired, and it also suggested that the present method of scholarships needed considerable modification. He should like to believe that the remark quoted by the author of the business house that "We must have the best ability that we can command, and it is to our interest to pay well to attain it," was absolutely true, especially in connection with commerce. He thought the tables the author had shown referred more to technical experts and not so much to the commercial side of the business. A great deal had yet to be done to get the best educated men into commerce, to find a door as it were into the City different from the present one, which was largely a matter of influence. There was an indication in the paper that the author thought far more of a wide and deep education of a general character than he did of what might be called an education of the process type, such as was seen in the planning of a particular technical school where much was devoted to processes as compared to what was devoted to true education. Some little time ago he was concerned in a report that dealt with an institution of a highly scientific character, and on showing the report to one of the ablest minds in England he was told: "It is no use bothering your head about that. Englishmen can never be great scientists. The English characteristics are of a practical kind." He did not think that was true. England had

Hosted by Google

been slow to adopt what might be called sound educational systems for the mass of her population, and there had been a tendency on the part of those who had not been well educated to call out for practical men. His own experience of managing men was that a man could be kept far too long at one particular job; there was nothing so soul-destroying as what might be called over-development in a particular direction. He got to know that particular work, but his ability was killed for any other purpose. He should like to know why the author thought that the schoolmaster would not have much say in the solution of the problem. The diagrams the author had given seemed to indicate one thing, that the First Class man was a first-class man. It would have been interesting to follow up the cases of the nineteen classical men, because possibly it would be found that in their schools they were kept on the classical side owing to the fact that they were the ablest students in the school. It had been true of most public schools, and he believed it was true also of most secondary schools, that the ablest pupils had been kept in what was regarded as the best side of the school. He did not think it mattered as a rule whether the First Class man was put on to one subject or another. Many of the men would have done their mathematics as well as they had done their classics, while others would do classics as well as they had done mathematics. His impression was that men learnt by compartments, that the mind ran far more in compartments than had hitherto been appreciated. In other words, a man might learn one subject very well, but his experience in learning it might be really of very little use to him when he turned to another subject, unless he was really a keen man. What was really wanted, therefore, was first-class ability and keenness in turning almost in any direction. But that keenness was kept up by a wide range of ideas, and that was where the real benefit of a classical education came in. It was far less narrow even than what was called a good, broad, scientific education. He might illustrate the point of compartments a little further. The most distinguished scientists were men who were engaged day by day in weighing evidence as to one chemical product, and judging development in one direction or another; but if one of those scientists were put on the judge's bench for six months he might show that the capacity for weighing evidence in one direction might be of great benefit from the point of view of weighing evidence in another. He believed that after six or twelve months' experience in the second position, the first-class scientist might become a first-class judge. He was interested in seeing the list of subjects which an industrial chemist was supposed to be acquainted with, but he thought the author would prefer a good general education to specialisation of that kind. Nowadays, if the head of a great shipbuilding firm wanted to know how to apply oil-engines to the propulsion of ships, he did not study it as one would do in a laboratory, but he went to the people who made oil-engines, and to those who were experimenting on the subject, and very soon appreciated the advantages of oil-engines from the point of view of propulsion of ships. There was one important aspect of industrial chemistry which had not been mentioned. He had been told within the last twenty-four hours by a chemist who had applied himself to photography, a young man who was getting a large salary, that there was room at the present moment for from ten to twenty chemists versed in the application of chemistry to photography. With regard to bio-chemistry, the very widest fields were being opened up to able young men. The British Empire contained within it more acres devoted to rubber, tea, coffee and cocoa than any other large political division of the world, and he was told there were firms in London who would be glad to get young men of twenty to thirty who had the personal and technical qualifications to enable them to take a leading position in those fields. He also learnt, somewhat to his dismay, that the young men who had recently been sent out had been found in Germany. He was glad to think it was true that teaching in London was being developed on lines that would provide a good supply of young men for the purpose. He was glad also to see the note of hopefulness in the paper that things had greatly improved within the last ten years, and he thought that was due a good deal to what the universities had done, and to the work of men engaged in industrial enterprises. The British manufacturer or merchant after all was not such a bad fellow as he was painted.

Professor Roberts Beaumont said systematised science directed to the development or improvement of some industrial work or series of processes lay at the very foundation of commercial and industrial prosperity; but unless science was directed he thought it would fail to affect, as it ought to affect, the industry of this country, and would not reach those students who wished to prepare themselves for an industrial career. General education in science, whilst laying a broad foundation and giving a broad outlook on life, was not exactly the education which equipped a man for the modern industrial struggle. He did not care himself about the so-called German or American competition, provided that the scientific and technological classes of this country were filled with young men of intellectual capacity with a disposition to acquire the science and technique connected with industrial work. Mr. Blair had spoken of the processes of educational methods as though they were in some way distinct from scientific methods. It was a fact that where one had first experiment which was educational—the training of the mind, the demonstration of principles and data—and secondly experiment for investigation and research, there was the very essence of science. In the most technical subjects, mining or textile, there was a scheme of experiment of the first type pursued by the advanced student of the second type,

and a combination of those two produced a science requiring exactly the same type of mental capacity as any other branch of science which might be demonstrated in the lecture room. He had had considerable experience of human capacity for the reception and utilisation of knowledge, and was one of those who suggested to the West Riding County Council that they should establish scholarships to select from the deserving and intellectually capable in the local schools the children of working-men for drafting into the university, where they might acquire a full training in the science and technology of their subjects. With regard to the possibility of such men attaining success, he held that at the end of their courses of study, unless one could find for them a good position —not necessarily good in a financial sense, but a position in which a rapid advance could be made to higher attainments—the purpose for which the educational scheme was established would fail. His experience was that scientific training had been one of the greatest boons ever given to the country. He could remember the days of absolute prejudice against scientific education in connection with industrial work, but it was recognised now to be a necessary preparation for industrial work. The question that arose was whether appointments were being obtained by those who were trained in the universities. His experience enabled him to say that men trained in the universities were occupying good positions in Japan, China, India, South Africa, Australia, New Zealand, Canada, America, and most of the Continental countries, and that in itself was evidence of the efficiency of the tuition and the value of scientific education as a groundwork for industrial pursuit. At home the advantages had been equally great. But such education must touch the worker of every grade of industry. Wherever a man exercised intellectual capacity in his work he had a right to benefit in any educational scheme of science in relation to industry.

MR. VERNON M. MARTIN said that as a younger member of a firm who felt they had attained a certain amount of prosperity by the older methods, he might say that when some of the younger members of the staff went off to the war in South Africa, the firm determined to approach the Appointments Board at Cambridge to see what they could obtain. He was deputed to go to Cambridge, and was quite astonished at the amount of talent which was available. The firm had never regretted the step then taken, and, when another vacancy was created, those who originally opposed the suggestion were the first to ask for another man of the same type.

MR. RICHARD B. PILCHER (Registrar of the Institute of Chemistry) said the Institute drew its best candidates for examinations from some thirty recognised colleges and universities, and all the candidates were required to have had the kind of training given at Cambridge. They had to go through a course of at least three years' systematic day training of a university character before being admitted to the professional examinations. At the present day some 45 per cent. of members had university degrees in addition to their fellowship or associateship, and if associateships of the Royal College of Science and diplomas of that order were included, the percentage would be much higher. The Institute had 1,400 members, and he thought there were very few bodies that could claim such a high representation of university men. Their standard of practical chemistry was very high, and it was not to be wondered at that very few of the members were unemployed; it would be difficult for him to name two who were out of employment. It was also rare for any young associate to accept an appointment under £120 per annum. Salary was an important matter. It was his experience that when men reached from £200 to £250 a year they found it difficult to get any further unless they were in a place that afforded considerable prospects. It was an important matter to consider what the young man was going to do when he had the training. In one big laboratory alone he had placed ten men during the past year on a starting salary of £120, and four men at £150, with guaranteed rises of £10 a year for four years, and a definite contract at the end of that time in a certain well-known works. As a young man who had to pay for his children's education, he felt it rather a hardship that scholarships were restricted to the children of people earning no more than £160 a year. Having regard to the expenses of education, he thought there were a large number of people with moderate salaries who would feel it a great benefit if such scholarships were opened to their children. He considered that a time was now coming when many vacancies, particularly in the teaching profession, were likely to become open, chiefly owing to the fact that the men who were appointed thirty-five or forty years ago, when so many new institutions were established, were now getting old and ready to retire.

MR. HORACE M. WYATT looked upon the paper as setting forth the truth that a liberal education was essential even in the most specialised professions, and he thought the success of university men was due as much to the liberal education received at a university as to the efficiency of the scientific training. The liberal education of a public school and university brought out certain qualities which were of the greatest possible value in business, and business men were beginning to realise this fact, and would realise it more fully in the future. A man who had passed through a public school and the university had certain ideals of discipline both with regard to himself and those under him, possessed tact, and had a code of honour which created respect. During the last few years he had managed to get into the firm with which he was connected five university men, three from Oxford and two from Cambridge, and the success of the experiments had led to his being asked by

Hosted by Google

the various departments to obtain others. He regretted that there existed no Appointments Board, dealing with public-school boys who did not go on to the universities. Such a boy had had a training which fitted him for certain posts, but there was no organisation to help him to get them. He had given some consideration to the matter, and in the event of sufficient influential men interesting themselves in the formation of a board or committee, he believed the matter could be dealt with, without the necessity, in the first instance, of any financial assistance, as that would be forthcoming from men who believed in the principle that something definite should be done to bring the public-school boy into direct contact with the commercial community.

MR. WALTER F. REID said he had found employment for some hundreds of young men in various industries, especially those connected with chemical products, and he believed there were many places to be found for highly-trained men, particularly those who had passed the Fellowship examination of the Institute of Chemistry. But nothing had been said as to men of lower grade, such as foremen, who were absolutely necessary in all works. France had long ago realised the necessity not only for training in the higher branches, but for training those whom they had to control, the men who were actually engaged in industrial work. He thought that to some extent the author had made no clear distinction between industry and commerce, and he was of opinion that the men dealt with in the diagrams had chiefly gone into commerce. A large commercial concern required men with ability different from that required to manage large industrial works. In his presidential address to the Society of Chemical Industry, at Sheffield, he had quoted some interesting figures given by Mr. Barker North. Taking the nine chief industries in the country, Mr. North analysed the amount per £100 paid in wages and salaries, and showed that the chemical manufacturer expended £11 7*s*. in salaries and £88 3*s*. in wages. The average output in value of the industries per head of those employed was £93, while the yield per head of those employed in the chemical industry was £185. It would be found that the value to the nation of trained men paid over and over again the cost of the education they received. With regard to the aniline industry, which was the *bête noir* of the average manufacturer, it was not quite true to say that when Hofmann returned to Germany he took the aniline industry with him. As one who followed him to Germany, he could say that Hofmann was not a colour chemist, and did not claim to be so or desire his students to specialise in that industry. English manufacturers at that time controlled the business by their patents, and made so much money out of it that they ceased to care whether the industry developed or not, and when the thing dropped, the Germans took it up, and by skill and patience developed it to an enormous extent. With regard to the quotation from the *Journal of the Society of Chemical Industry*, setting forth the number of things necessary for the training of a chemist, it should be understood that it referred not to the student, but to the chemist in charge of works, who not only had to have some knowledge of the subjects mentioned, but also had to know something of mineralogy. Under modern industrial conditions, a man, to keep himself up to date, had to study day and night to be on equal terms with his competitors.

MR. JOHN W. SHAW said that the author appeared to be somewhat pessimistic with regard to appointments under municipal corporations, but there was no doubt that in the future municipalities would be employing more and more trained men, and it would be of benefit if the author could state what he considered to be the weak spot in municipal service, and point out in what direction it could be strengthened. It seemed to him that the State and municipalities had the advantage that they could offer university men posts quite free from the ordinary commercial spirit, and more in accordance with the spirit of pure science, and, having regard to the fact that they offered a steadier career, could afford to buy ability at a lower figure than the commercial man.

MR. F. W. GOODENOUGH thought the reason why a door had not been opened into the City was that universities had so far failed to realise that there was a science of business. There was a Chair of Business Science at Harvard, and the Americans were far ahead of this country in training men in scientific business administration as distinct from the science needed for manufacture.

MR. ROBERTS, replying to the discussion, said that with regard to the schoolmaster having control, it seemed to him that educational reformers pushed their own fads so hard that the unfortunate schoolmaster was squeezed out. If the Board of Education succeeded in their present endeavour to organise the profession from top to bottom so that the elementary, secondary, and technical teachers might be one in expression of opinion, possibly the schoolmasters would have a chance, but at present they were between the upper and nether millstones, regarded, as could be seen by the salaries, as almost beneath contempt. He did not shut his eyes to the good work done by the Board of Education and the London County Council, and such bodies, but until the teaching profession was organised there would be no satisfactory method of giving weight to their opinions. He agreed with Mr. Blair as to the good stuff produced in the small towns and villages, and wished he could be as satisfied about the large towns. He was told it was the same all over Europe, and that even in Japan the people who congregated in the industrial towns were gradually losing their old characteristics and physique and vigour. He was hardly in absolute agreement with Professor Beaumont; they

Hosted by Google

naturally approached the matter from different points. Perhaps the truth, as in other cases, might be found in the wise remark made to him by Sir Benjamin Brown, when discussing the training of engineers—whether the boy should go straight into the works after leaving the university, or should adopt the half-time system, or should go into the works before entering the university—that "the truth is, there is no one way of producing an engineer; there are a dozen or more." He was interested in Mr. Wyatt's suggestion with regard to the public-school boy, and knew of one case of a public school with a small Appointments Board, the secretary of which was inundated with applications. Probably there was a wide field in that direction, and it would be thought that the headmasters of such schools as the City of London and St. Paul's would have numerous applications. With regard to the diagrams, No. 1 dealt with commercial men, and No. 3 with men who had entered industries. With reference to municipal corporations, it seemed to him the matter was carried out in what might be called a hole-and-corner way. There was possibly an advertisement in the public press, but he was not always satisfied that the committees dealing with the applications were really competent to judge of professional standing and experience. He believed that if the applications were referred to a committee of engineers, possibly the Institution of Civil Engineers itself, the ultimate selection being made by the corporation, it would be a better method of laying stress upon the professional value of the applications.

On the motion of the Chairman, a hearty vote of thanks was accorded to the author, and the meeting terminated.

THE DEVELOPMENTS OF THE TEXTILE INDUSTRY.

In general the textile industries are well engaged, and the most troublesome complications in front of them are rather external than internal. The cotton trade has not lost its sense of thankfulness at being back in full work, and its looms have assured work for six months or more at profits which cotton spinners envy, but do not currently obtain. A chance of a fall in raw cotton soon, and an uncertain prospect for the autumn, are foreseen contingencies. India, which is always the largest market, has been much the largest buyer this year, and before the year end may be uncomfortably overloaded. There remains the question of how far China will have recovered its buying power by that time, and of what other markets can do to compensate for the anticipated slackening of Indian demand.

A fall is expected also in the price of wool as soon as the delayed and accumulated supplies of South American cross-bred wool are available for transit. The finer botany or merino classes are comparatively unaffected, and spinners of these are in a better position than their fellows. After a three years' run of almost unexampled prosperity, worsted spinners have fallen upon times of relative adversity. After being the kings of the situation, able on the one hand to restrain the price of tops, or combed wool, and able on the other to pick and choose between customers and classes of business, they are reduced to a much humbler estate. Knowing the difficulty of getting yarn when it was wanted, their manufacturing customers ordered in excess of their actual requirements, and from day to day prices of wool and prices of yarn have both been against the spinner, whose profitable margins have been melting fast. Relatively to the amount of business done, the topmakers (who buy wool raw and sell it combed) have gained ground where spinners have lost. The worsted manufacturers who weave the cheaper yarns which are now forthcoming have suffered less than their suppliers. The carded woollen manufacturers who consume the short wools and rag wool have extremely little to complain about, although some of them join with worsted manufacturers in denouncing as an iniquity the hobble-skirt which has so restricted the yardage necessary to a dress.

The position of the stuff manufacturers whose traditional business is to produce light fabrics, mostly with a cotton warp and a worsted weft, might have been much more embarrassing but for the introduction of artificial silk. Many hundreds of looms in the Bradford area now run continuously in manufacturing fancy cotton cloths ornamented with threads of artificial silk. Doubtless, real silk is supplanted by the newcomer in one degree or another, but silk had already given way in this department before mercerised cotton. The viscose silk supplants mercerised cotton, and even mohair and bright wools, in making goods chiefly for evening or for tropical wear by women. Brightness is their prime characteristic, and coupled with this is a lightness of weight which is of great practical utility in reducing the final cost of goods which are charged with import duty upon a weight basis. The artificial silk is used preferably in slack twists, as it can only be twisted tightly at some sacrifice of lustre. Commonly, it is used as effect-threads more than as an integral part of the main structure, but there are cloths, simulating mohair, in which the entire weft is artificial silk. Great durability is not a claim that can be advanced for this material, and the artificial silk, besides having a more metallic glare, refuses to spread and cover so well in weaving as does natural silk. Nitrated silk and cupro-ammonium silk are not unknown and are admired for their lustre, but viscose silk, of the sort that is now made at the rate of twenty tons weekly in Coventry, is preferred for its behaviour under the rude strains of weaving, dyeing and cloth-finishing.

Silk producers question the right of articles made from cellulose to the title of artificial silk, and particularly resent the use of the now common abbreviation "art silk." No such proprietary interest is seriously menaced by a material lately

Hosted by Google

introduced into this country under the name of artificial wool. In point of fact it is neither wool nor artificial, although certain resemblances to wool cannot be denied. In curl, length of staple, and lustre this new preparation of jute passes easily for wool at a little distance. The colour is a golden brown naturally, but after bleaching, the material is like enough to scoured wool in colour. The harshness, brittleness, and sadness of the material proclaim its vegetable origin to the hand. It can be intermixed readily with wool by the carding processes, and blankets made half of "artificial" and half of animal wool are barely distinguishable from all-wool blankets at sight. There remains, however, the all-important question of cost, and at the price at which the prepared jute is offered, a large selection can be had of raw materials which originated with the sheep, although they may have served in some form of manufactures subsequently. Woollen wastes and shoddy are so various and abundant that the opportunities of replacing them profitably are naturally small. Any wool substitute, to realise a high price, must be capable of use in the worsted industry. Given a fibre which could be intimately intermixed and drawn into a perfect sliver in company with the longer worsted wools, there would be room for exacting a higher price than owners of carding-engines and mule-frames are likely to pay.

The worsted industry is incapacitated from the employment of the great rag reserves, which form a larger bulk of available textile material than is always realised. Exact particulars of the dimensions of the woollen rag industry are wanting, but it is known that the imports into this country have been in the last two years respectively 59,000 and 56,000 tons, entered at an average value of about £19 2*s.* 6*d.* per ton. The number of rag-pulling machines existent in 1904 is also known, and, making the safe assumption that the nine hundred machines treat not less than two tons a week, a British consumption of 90,000 tons per annum can be calculated. The probability that the number of machines has increased, and the certainty that in busy times the machinery runs longer hours, are both disregarded in arriving at this minimum total. A foreign supply approximating to one thousand tons a week is no new thing in Dewsbury experience, and in and about that place substantially the whole bulk is worked. Cheap rags give cheap tweeds and costume cloths, cheap meltons, serges, president and beaver cloth, and make possible the export of as great a quantity as the ninety-eight million yards of last year. It is an odd feature of the English rag trade that the United States should have become the principal source of supply. Rather more than one-third of the imported rags of 1911 were of American origin, and these 19,123 tons may be compared with the 8,815 tons of two years previously, although not directly with totals before that date. There were no imports from America of sufficient importance to be separately recorded before 1909.

Price maintenance is a term little heard within the great body of textile industry. The industries are too little concerned with proprietary names, small specialities, and advertising, to think much of the prices their products ultimately fetch or of the sufficiency of the profit left to the retailer. The announcement that J. and P. Coats, Ltd., the head of the sewing-cotton trade, are to take their customers' opinions on the desirability of stereotyping the retail price of reels of thread, makes easily the most important textile departure in this direction. It is apparent that many drapers have in the past sold thread at prices leaving no profit to themselves, and there is scarcely a doubt that the manufacturers could enforce the maintenance of standard selling prices. The accusation that the great Paisley company holds a monopoly has always been rejected, but in the textile industries no undertaking holds dominion over manufacture in so many lands and none discloses equal profits. The lead would be as important as all the new measures of so great a concern must be. Who would—even who could—follow in a similar way can hardly be guessed at the present time. By far the greater bulk of textile goods are not turned out from the mill in a condition ready for immediate consumption, and bear no definite indication of the manufacturer's identity.

CORRESPONDENCE.

THE ETYMOLOGY OF AGAR-AGAR, "PAW-PAW," AND "CHASUM."

In the last number [February 23rd] of our *Journal*, several English trade names of foreign economic productions occur, a knowledge of the etymology of which is very necessary for a proper understanding of the nature of the commercial articles to which they have been given.

1. *Agar-agar*, so misleadingly synonymed in commerce "Japanese *Isinglass*," is the correct Malayan name, meaning "sea-weed," of *Gracilaria lichenoides*, N. O. Algae [the substance of which is amylaceous, and quite indigestible, and not gelatinous, as is that of isinglass], and other species of Algae; their chief use in this country being in the preparation by bacteriologists of "culture media."

2. "Paw-paw" is an exceedingly sluggardised corruption I have never seen, or heard of, before, of the Malayan name, *papaya*, of the subarborescent palmoid, and herbaceous perennial Passion-flower, *Carica Papaya*, of South America; acclimatised in the gardens of tropical Africa, and all southern Asia, by the Portuguese, in the course of their earliest navigations, conquests, and commerce throughout the East. All its Indian names are corruptions of its Malayan name, and as none of them has an Indian meaning, I assume that its Malayan name may be a corruption of its native South American name. Waller refers to it and its castor-oil-plant-like leaves, and "lovely [pepo-like] fruits," under the name of *papaw;*

Hosted by Google

but whether on the authority of travellers in the Americas or in Asia I do not know. The plant is a great ornament of Indian gardens, with its palm-like growth, and wreathed crown of cucurbitaceous leaves, and its melon-like fruits clustered below them; but its fruits, although beautifully moulded, and soft as butter, are very insipid, and a little unpleasant in flavour, while its pungent seeds and sub-acrid milk-like juice, necessitate its being handled with care in the eating of it. I was one of the first to draw attention in this country, through the late Mr. Daniel Hanbury, to its seeds and its juice, both of the fruit and the leaves; and they are now largely used here in the preparation of Papain, or Papayotin. The Anglo-Indian names are "Papaya," "Papay-Mango," "Castor Tree" from its leaves, and "Melon Tree" from its fruit.

3. "Chasum," occurring in my remarks on Mr. Frank Warner's lecture, cannot be an Indian name of any sort, condition, or form of silk. In Bombay it is one of the vernacular names of "gram" [Portuguese *grao*, out of the Latin "granum"], *i.e.*, the "Chick-pea" ["small," "young"-pea, cf. chickabiddy], *Cicer arietinum*; and again, pronounced quickly, *chas'm*, it means the "Evil-Eye." Compare Chas'mah-i-bad, the name of a spring in Khorassan, which, when it becomes polluted, is buffeted by a strong wind until it runs pure again [Job xxxvii. 21]. This word, in its use in the silk industry, utterly baffles me, and I adventure the explanation that it is an immortalised typographical error for the word *Rashum* [with a capital R], the Hindustani name of the silk waste from reeling, etc., used in the weaving of inferior carpets in India.

GEORGE BIRDWOOD.

THE ROYAL COLLEGE OF ART.

The *Journal* of February 9th has a review of Mr. C. R. Ashbee's book, "Should we Stop Teaching Art?" Both he and the reviewer make use of statistics presented in the Board of Education's Committee's Report upon the Royal College of Art. For some years before 1908 I was in close official touch with that institution, taking part in its reorganisation during the years 1899 and 1900. Its future is still a matter of interest to me. Now, the statistics published with the report gave the Committee the impression that of some 450 students who passed through the College courses during a recent period of ten years, thirty-two only have made the practice of art in any form their livelihood, while 136 other students have become teachers, and 230 other past students' occupations are returned as unknown.

The inaccuracy of these figures was the subject of a letter that appeared in the *Times* on November 7th, 1911. I have good reason to believe that the number of the past students referred to, and who are now engaged in the practice of art and of teaching, is at least 390, and that of the balance of sixty unaccounted for inquiry would show that some retired before completing their course of instruction, some died, and that the remainder—say thirty only—have taken up pursuits other than art. Hence, the number of students unaccounted for cannot be over 50 per cent., as shown in the official statistics, but something between 5 and 6 per cent., so that contentions founded on an unaccountability of over 50 per cent. become of extremely doubtful value.

Under the dispensation which has succeeded that of the late Secretary of the Board of Education, who was responsible for the preparation of the statistics put before the Committee, rectification, if it has not already been taken in hand, will no doubt be made.

Meanwhile, it is a pity that the Committee's Report, in so far as it is flavoured by the suggestiveness of inaccurate statistics, should be taken seriously, as for instance, when many passages were quoted from it in the course of the otherwise admirable paper read by Mr. Frank Warner at the Society's meeting on Wednesday, the 21st February last. It is obviously good to consider and discuss how the usefulness of the Royal College of Art in prosecuting its purposes within a well-defined scope may be developed, but there seems to be little advantage in the repetition of polished phrases having the guise of *ex cathedra* pronouncements conveying wholesale condemnation which is found to spring from "otiose conjecture," stimulated by inaccurate statistics.

Clearly, an important committee should not have been provided with misleading materials.

ALAN S. COLE.

OBITUARY.

COLONEL SIR JAMES BUCKINGHAM, C.I.E.—Sir James Buckingham died at his residence in Ashley-gardens on February 27th. He was born in 1843 at Doddescombsleigh, South Devon, and was educated at Blandford Grammar School and Cheltenham College, where he distinguished himself especially in all forms of sport. When he competed at an athletic meeting at Torquay at the age of twenty-three he won all the events. Shortly after this he went out as an assistant on the Torehut tea estate, Assam, and subsequently was appointed manager of the Angoorie estate, a post which he held for thirty-five years. He was recognised as a high authority on all matters affecting the tea industry. For many years chairman of the Assam branch of the Tea Association, he was a member of the Supreme Legislative Council in 1893–4, and again in 1899–1901, being on the latter occasion specially appointed by Lord Curzon's Government in connection with the measure to amend the law relating to the importation of indentured coolie labour which had the chief place in the programme of the Calcutta Session of 1901. He served on the Select Committee, and had a substantial share in bringing about the compromise on the question of wages whereby the conflict between Sir Henry Cotton, the Chief Commissioner, and the planters was in some degree adjusted. On several occasions he

Hosted by Google

submitted valuable memoranda to Government on various aspects of the labour problem and other matters of importance. Another service he rendered the industry was his discovery about 1884 of the value of the leguminous *sau* tree (*Allizzia stipulata*) on the estates of the Assam Valley as a fertiliser and a protective agent against insect pests.

Mr. Buckingham did much to promote and develop the Volunteer movement in Assam. About 1884 he raised and became commandant of the Sibsangur Mounted Rifles, which six years later was enlarged into the Assam Valley Light Horse and Administrative Battalion. He was made a C.I.E. in 1890, and from 1895 to 1898 he was honorary A.D.C. to the Viceroy, Lord Elgin.

When he retired from Assam in 1906 he received the honour of knighthood, and on being appointed secretary of the Indian Tea Association here in June, 1906, he did much to extend the range of its activity and usefulness. He joined the Royal Society of Arts in 1908.

George Attwood, M.Inst.C.E., F.G.S., F.C.S.—Mr. George Attwood died at his residence, Steyning Manor, Somerset, on February 9th. Born at Carlisle in 1845, he was educated at Edward VI.'s Grammar School, Lichfield, and a the age of sixteen he began his professional career under his father and Mr. W. W. Palmer in California and Nevada. He constructed large engineering works both in America and in Africa, and he practised as a consulting civil and mining engineer in London. He also published numerous scientific papers. He joined the Royal Society of Arts in 1881. He was a member of various other scientific and professional bodies, and a Justice of the Peace for British Columbia.

George Edward Pritchett, F.R.I.B.A., F.S.A.—The death has occurred of Mr. G. E. Pritchett, of Oak Hall, Bishop's Stortford, in his eighty-eighth year. Mr. Pritchett was the oldest Carthusian, and was present at the recent tercentenary banquet. He was the architect of a number of churches in Hertfordshire and Essex. He became a member of the Royal Society of Arts in 1873.

NOTES ON BOOKS.

The Groundwork of British History. By George Townsend Warner, M.A., and C. H. K. Marten, M.A. London: Blackie & Son, Ltd. 6*s*.

This book has been designed to meet the requirements of middle and upper forms in public schools. The first part, from 55 B.C. to 1603, is the work of Mr. Warner, Master of the Modern Side at Harrow; the second, which carries us up to 1911, is by Mr. Marten, Assistant Master at Eton. In writing the work, the principal object of the authors has been to impress upon the boy "some idea of the origin and sequence and relation of events," to give him some notion of history as a whole. "Our aim"—to quote the preface—"is to provide the reader with a groundwork, at once solid and broad-based, upon which increasing knowledge may gradually be built; to trace out the main threads of British history, omitting small and unfruitful details; to treat events in logical sequence by pursuing one subject at a time; and to concentrate the mind upon what was the chief policy or course of action in each age."

In other words, the authors have endeavoured to treat history in a rational manner, and thereby to encourage the faculties of understanding and reason rather than mere memory. There can, of course, be no question that this method is the right one, and that by this method alone can history be made a profitable study. If a boy has in his mind a reasoned groundwork of events, and knows their why and wherefore, he cannot produce "those grotesque onslaughts upon chronology and probability with which we are all acquainted."

How far it may be possible to interest youthful students in such subjects as scientific progress, artistic and literary changes, industrial advances and social development, it may be hard to say, but without too severely criticising the method of our two accomplished authors, it may perhaps be suggested that they might have experimented a little further in this direction than they have cared to do, especially in the latter part of the book. A chapter of less than twenty pages, "The Industrial Revolution and Social Progress,", is all that is allotted to the history of the social, scientific, economic, and industrial changes that have taken place since 1750. It is, of course, utterly impossible even to summarise within these limits the events of an era in which such profound alterations were made in all the conditions of human life by the development of scientific knowledge and its innumerable applications to human needs. Nor are the statements made always accurate or even intelligible. Watt did not "produce . . . the first efficient steam-engine." Such a statement as, "At first the steam-engine had only a vertical motion . . . later, however, was discovered the possibility of a rotatory and parallel motion," could not have been made by anybody having the most elementary mechanical knowledge, and it is a pity that it should be admitted into a book of this sort. It is, however, fair to say that there are not many similar passages to be found, and after all this one is perhaps due to the carelessness of a scholar writing about technicalities. The fault is extreme compression. But what is a historian, however accomplished, to do who tries to squeeze the history of invention from Kay to Marconi, of periodical literature from Defoe to Delane, of science from Cavendish to Darwin, of medicine from Sydenham to Lister, of industrial economics from Elizabeth's Act to the Workmen's Compensation Acts, of the Post Office from Palmer to Rowland Hill—to mention a few out of many topics—into twenty small pages?

Hosted by Google

A paragraph of a dozen lines is all that can be spared for the literature and art of the eighteenth century, while exactly half that amount is deemed sufficient for that of the nineteenth.

It may, however, appear ungracious to dwell on the defects of a useful and compendious history, but the authors in their preface lead us to expect a rather fuller treatment of social matters, as distinct from political, than is actually to be found in their pages. Perhaps the expectation was unreasonable, and the reviewer should have been content to express his admiration for what the authors have really provided—an excellent and well-written history of England from the earliest times to the present day.

Grants in Aid: A Criticism and a Proposal. By Sidney Webb. London: Longmans, Green & Co. 5*s*. net.

Municipal Origins. By Frederick H. Spencer, LL.B. London: Constable & Co., Ltd. 10*s*. 6*d*. net.

The History of Local Rates in England. By Edwin Cannan, M.A., LL.D. Second Edition. London: P. S. King & Son. 2*s*. 6*d*.

These three volumes all form part of the excellent series of monographs by writers connected with the London School of Economics, edited by the Director, the Hon. W. Pember Reeves.

Mr. Sidney Webb makes an interesting inquiry into the history and distribution of our grants in aid. Their whole development, he states, has taken place since 1832. "In 1830 the total payments from the national exchequer to such local authorities as then existed, which were mostly odds and ends of historical survivals, seem to have been insignificant, in fact, considerably under £100,000 . . . In 1870 I gather the total may have been nearing two millions." By 1880 it had reached what was then thought the colossal sum of five millions. By 1910 it exceeded sixteen millions; for 1911-12 it will probably reach something like thirty millions, and "by 1920, when the total revenue of the national Government will probably exceed £200,000,000, the Chancellor of the Exchequer of the day will find himself paying away to the local authorities as much as a quarter of all he receives, or fifty millions sterling."

It will be seen that the problem dealt with is vast and important. Mr. Sidney Webb is not opposed to the system of grants in aid, *per se;* he only objects to it as it at present exists, and he desires to see some intelligent and intelligible principle in place of the haphazard rule of thumb which at present manages or mismanages it. "Any competent revision," he says, "on scientific lines of the financial relations between local authorities and the Exchequer could hardly fail to mean (*a*) a great advance in public health administration in backward districts, especially as regards phthisis, maternity, and infancy; (*b*) a further onward stride in education, including medical treatment and provision of what is required for necessitous children; (*c*) extensive developments in the case of the feeble-minded and mentally defective; and (*d*) a quickening of the whole local administration."

Mr. Spencer's volume gives, as its sub-title explains, an account of English private bill legislation relating to local government from 1740 to 1835. The work is commended by Sir Edward Clarke, in a preface, as "the best and most complete account that I have yet seen of the beginnings of that system of local government and administration of which England is very justly proud." In many cases these beginnings are exceedingly obscure. The journals of the Commons or the Lords throw little light upon them, and as a general rule the minutes of vestries are the main source of our information. Mr. Spencer appears to have been at immense pains in gathering his materials, and his book contains a fund of information which is now brought together for the first time, and which should prove of great service to all interested in the subject.

Professor Cannan's volume, when it first appeared, formed No. 1 of the series of the London School of Economics. It has now been considerably enlarged, the principal additions being Chapters VI., VII., and VIII., in which he discusses the struggle to shift some of the expenses borne by local rates on to national funds, the equity of local rates, and their economy.

An Elementary Text-Book of Coal-Mining. By Robert Peel. Sixteenth Edition. London: Blackie & Son, Ltd. 3*s*.

The fact that this well-known text-book has reached its sixteenth edition is a sure proof of its continued popularity. In the present edition the author has added a chapter on Coal-cutting by Machinery, while the work generally has been revised and brought up to date. For instance, Mr. Peel gives an account and an illustration of the Cunynghame-Cadman Gas-detecting Device, which was first described by Sir Henry Cunynghame in the paper on "Methods of Detecting Fire-damp in Mines," which he read before the Society in November, 1910.

Practical Chemistry for Engineering Students. By Arthur J. Hale, B.Sc. London: Longmans, Green & Co. 3*s*. net.

The scope of this book is clearly indicated by its title. Mr. Hale (who is Lecturer and Demonstrator in Chemistry at the City and Guilds Technical College, Finsbury, and is, therefore, specially familiar with the chemical requirements of engineering students) has laid down a scheme of practical laboratory work in which he deals mainly with what may be called "engineering" materials. Most of the experiments described are quantitative, and treat more especially of such problems as the analysis of water, fuel, furnace gases, iron, steel, oils, cements and alloys. An introductory note is contributed by Professor Meldola, in which he discusses the importance of a knowledge of chemistry to an engineer.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

March 6.—T. Thorne Baker, "Some Modern Problems of Illumination: The Measurement and Comparison of Light Sources." James Swinburne, F.R.S., will preside.

March 13.—Professor Ernest A. Gardner, M.A., "Greek Sculpture."

March 20.—F. Martin Duncan, "The Work of the Marine Biological Association." P. Chalmers Mitchell, D.Sc., LL.D., F.R.S., will preside.

March 27.—Theodore E. Salvesen, "The Whaling Industry of To-day."

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

March 14.—E. A. Gait, I.C.S., C.I.E., Census Commissioner for India, "The Indian Census of 1911."

April 25.—Sir John O. Miller, K.C.S.I., "The Central Provinces."

May 16.—Neville Priestley, Managing Director, South Indian Railway, "Indian Railways."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

March 26.—Leonard Lovegrove, "British North Borneo."

May 7.—Alan Burgoyne, M.P., "Colonial Vine Culture."

May 21.—The Hon. J. G. Jenkins, "Australian Railways."

Cantor Lectures.

Monday evenings, at 8 o'clock:—

Luther Hooper, "The Loom and Spindle: Past, Present, and Future." Three Lectures.

Syllabus.

Lecture II.—March 4.—*The Handloom for Automatic Weaving, Plain and Ornamental, and the Modern Spindle.*—Leonardo da Vinci's sketch of the spinning wheel *flier* and *bobbin* attachment—Its general adoption in Europe for hand spinning—Varieties of the motion developed—Inventors of spinning machinery—Hargreave's *Jenny*, Arkwright's *Waterframe*, Crompton's *Mule*, and others—Weaving in ancient China—Horizontal looms—Indian looms—Old English and other looms for silk weaving—Chinese silk loom—Invention of satin weaving—Looms for weaving small designs—Double *harness* weaving—Long- and short-eyed *leashes*—Chinese *draw-loom*—The *comber board*, its great importance—The *pulley box*—The tail of the loom—The *simple*—The *tie-up* of the design—The *divided* comber board and other arrangements for *tissue* weaving—European draw-looms—Examples of draw-loom woven textiles of various periods.

Lecture III.—March 11.—*The Modern Loom for Plain and Ornamental Weaving and its Future Development.*—Eighteenth century inventions compared with those of earlier periods—The drawboy—The drawboy machine—The Jacquard machine or *draw-engine*—Kay's *fly shuttle*, its great utility and unexpected value—The first power-looms—Application of steam power to the loom—General adoption of the factory system in textile industries—Comparison of hand and power-looms as regards quality and speed of weaving—The effect of machine weaving on the workers—Defects of the power-loom—Electricity as applied to the loom—The loom of the future.

Noel Heaton, B.Sc., F.C.S., "Materials and Methods of Decorative Painting." Three Lectures.

March 18, 25, April 1.

Howard Lectures.

Monday evenings, at 8 o'clock:—

Captain H. R. Sankey, R.E., M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

April 29, May 6, 13, 20.

Dates to be hereafter announced:—

Charles C. Allom, "The Development of Artistic Skill in the Applied Arts."

Ernest Kilburn Scott, Assoc.M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere."

E. D. Morel, "British Rule in Nigeria."

Gordon Craig, "Art of the Theatre." Miss Ellen Terry will preside.

George Fletcher, "Technical Education in Ireland."

William Burton, M.A., F.C.S., "Ancient Egyptian Ceramics."

MEETINGS FOR THE ENSUING WEEK.

Monday, March 4...Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Luther Hooper, "The Loom and Spindle: Past, Present and Future." (Lecture II.)

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 7.30 p.m. Mr. Henry C. Adams, "The Trolley Vehicle System of Rail-less Traction."

Chemical Industry (London Section), Burlington House, W., 8 p.m. 1. Dr. C. E. Kenneth Mees, "The Photographic Process." 2. Dr. J. Gordon Parker and Mr. J. R. Blockey, "Notes on the Estimation of Glucose in Leather."

Hosted by Google

Victoria Institute, 1 Adelphi-terrace, W.C., 4.30 p.m. The Bishop of Down, "Difficulties of Belief."

Aeronautical, at the Royal United Service Institution, Whitehall, S.W., 8.30 p.m. Lieutenant C. M. Waterlow, "Military Airships."

TUESDAY, MARCH 5...Cold Storage and Ice Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 7.30 p.m.

Roman Studies, Society for the Promotion of, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Professor F. Haverfield, "Some Problems of Roman Gaul."

Royal Institution, Albemarle-street, W., 3 p.m. Professor E. G. Coker, "Optical Determination of Stress, and some Applications to Engineering Problems." (Lecture II.)

Alpine Club, 23 Savile-row, W., 8.30 p.m.

Royal United Service Institution, Whitehall, S.W., 4 p.m. Anniversary Meeting. Report of Referees on Millitary Essays for 1911.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Professor J. Goodman's papers, "Roller and Ball Bearings," and "The Testing of Anti-Friction Bearing Metals."

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. J. W. Lumb, "On the Desirability of the Formation of a British School of Pictorial Photography."

Zoological, Regent's Park, N.W., 8.30 p.m. 1. Mr. H. L. Hawkins, "The Classification, Morphology, and Evolution of the Echinoidea Holectypoida.' 2. Mr. H. G. Plimmer, "Blood Parasites found in the Zoological Gardens during the four years 1908–1911." 3. Dr. G. O. Sars, "Zoological Results of the Third Tanganyika Expedition, conducted by Dr. W. A. Cunnington, 1904–1906. Report on some Larval and Young Stages of Prawns from Lake Tanganyika." 4. Dr. Robert Broom, "On the Structure of the Internal Ear, and the Relation of the Basi-cranial Nerves in *Dicynodon*, and on the Homology of the Mammalian Auditory Ossicles."

WEDNESDAY, MARCH 6...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. T. Thorne Baker, "Some Modern Problems of Illumination: the Measurement and Comparison of Light Sources."

Automobile Engineers, 13, Queen Anne's-gate, S.W., 8 p.m. (Graduates' Section.) Mr. N. V. Page, "Maximum Power for Minimum Weight."

Public Analysts, at the Chemical Society's Rooms, Burlington House, Piccadilly, W., 8 p.m. 1. Mr. H. S. Shrewsbury, "A Method of Estimating Calcium Carbonate in Soils." 2. Mr. A. C. Chapman, "Standards for Malt Vinegar." 3. Messrs. G. D. Elsdon and Norman Evers, "The Estimation of Ammonia in Carbonated Waters." 4. Mr. George A. Stokes, "A Note on a New Preservative for Milk, Cream, etc."

Royal United Service Institution, Whitehall, S.W., 3 p.m. Lieutenant-Colonel E. C. Carter, "The New Transport System, its Principles and their Application."

Royal Archæological, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. Aymer Vallance, "Old Bridges in England and Wales."

THURSDAY, MARCH 7...British West African Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 3 p.m. Mrs. Mary Gaunt, "British West Africa."

Royal, Burlington House, W., 4.30 p.m.

Linnean, Burlington House, W., 8 p.m. 1. Professor Percy Groom, "Internodes of *Calamites*." 2. Miss Ethel M. Phillips, "Coloured drawings of Barbados plants." 3. Mr. E. A. Newell Arber, "On *Psygmophyllum majus*, sp. n., from the Lower Carboniferous Rocks of Newfoundland, together with a Revision of the Genus and Remarks on its Affinities." 4. The Rev. T. R. R. Stebbing, "Historic Doubts about *Vaunthompsonia*." 5. Dr. Otto Stapf, "Living specimens of Cactoid Euphorbias from South Africa (exhibited by permission of the Director, Royal Gardens, Kew)."

Chemical, Burlington House, W., 8.30 p.m. 1. Mr. A. Angel, "Isomeric Change of Diacylanilides into Acylaminoketones. Transformation of dibenzoylparachloro- (and Parabromo-) aniline into the Isomeric Benzoylchloro- (and Bromo-) amino Benzophenone." 2. Messrs. N. Bland and J. F. Thorpe, "The Chemistry of the Glutaconic Acids. Part III. — Glutaconic Acid and its β-elkyl Derivatives." 3. Messrs. W. J. Pope and J. Read, "Asymmetric Quinquevalent Nitrogen Compounds of Simple Molecular Constitution." 4. Mr. M. N. Banerjee, "The Interaction of Phosphorus and Potassium Hydroxide Solution." 5. Messrs. M. O. Forster and J. C. Withers, "The Triazo-group. Part XX. — Azomides of the Propane Series." 6. Mr. F. L. Pyman, "The Synthesis of Glyoxaline Derivatives allied to Pilocarpine." 7. Mr. H. S. Taylor, "Calcium Nitrate. Part I.—The Three-component System: Calcium Nitrate, Nitric Acid, Water at 25°." 8. Messrs. H. Bassett, Jun., and H. S. Taylor, "Calcium Nitrate. Part II.—The Two-component System, Calcium Nitrate, Water." 9. Mr. F. B. Thole, "Viscosity and Association. Part II.—The Viscosity of Geometrical Isomerides." 10. Mr. J. F. Thorpe, "The Chemistry of the Glutaconic Acids. A Correction." 11. Messrs. A. C. Sircar and E. R. Watson, "Azo-salicylic Acid and Azo-oxy-naphthoic Acid Dyes." 12. Mr. G. B. Neave, "The Catalytic Action of Copper at 300° C. on some Alcohols of the Terpene Group."

Royal Institution, Albemarle-street, W., 3 p.m. Professor Charles Oman, "Wellington's Army." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. F. Enoch, "Fairy Flies and their Hosts."

Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Mr. W. W. Lackie, "Tariffs for Electrical Energy, with Particular Reference to Domestic Tariffs."

FRIDAY, MARCH 8...Architects, Society of, 28, Bedford-square, W.C., 8 p.m. Mr. A. A. H. Scott, "The Testing of Materials."

Cyclists' Touring Club, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Annual Meeting.

Royal Institution, Albemarle-street, W., 9 p.m. Dr. A. W. Ward, "The Effects of the Thirty Years' War."

Malacological, Burlington House, W., 8 p.m. 1. Rev. A. H. Cooke, "The Distribution and Habits of *Alopia*, a subgenus of *Clausilia*." 2. Mr. H. Hannibal, "A Synopsis of the recent and tertiary Freshwater Mollusca of the Californian Province. Part I.—*Pelecypoda* and *Palmonata*." 3. Major M. Conolly, "Note on the existence of two editions of Férussac's 'Tableaux Systématiques.'" 4. Mr. E. A. Smith, "Note on *Pleurotoma bipartita* Smith."

Royal Astronomical, Burlington House, W., 5 p.m.

British Foundrymen's Association, Cannon-street Hotel, E.C., 8 p.m. Mr. H. Brearley, "Steel Castings."

Physical, Imperial College of Science, South Kensington, S.W., 8 p.m.

Medical Officers of Health, Society of, 1, Upper Montague-street, W.C., 5 p.m. Dr. G. A. Auden, "Open Air Schools."

SATURDAY, MARCH 9...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Molecular Physics." (Lecture III.)

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,094. VOL. LX.

FRIDAY, MARCH 8, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 11th, 8 p.m. (Cantor Lecture.) LUTHER HOOPER, "The Loom and Spindle: Past, Present, and Future." (Lecture III.)

WEDNESDAY, MARCH 13th, 8 p.m. (Ordinary Meeting.) PROFESSOR ERNEST A. GARDNER, M.A., Yates Professor of Archæology, University College, London, "Greek Sculpture." LORD SANDERSON, G.C.B., K.C.M.G., Chairman of the Council, will preside.

THURSDAY, MARCH 14th, 4.30 p.m. (Indian Section.) E. A. GAIT, I.C.S., C.I.E., Census Commissioner for India, "The Indian Census of 1911." The paper will be read by MR. J. D. ANDERSON, M.A., I.C.S. (retired). SIR THEODORE MORISON, K.C.I.E., M.A., will preside.

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, March 4th, MR. LUTHER HOOPER delivered the second lecture of his course on "The Loom and Spindle: Past, Present, and Future."

The lectures will be published in the *Journal* during the summer recess.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal of the Royal Society of Arts for 1912 early in May next, and they therefore invite members of the Society to forward to the Secretary on or before Saturday, March 30th, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded as follows in previous years:—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S., "for his great services to Arts, Manufactures, and Commerce, in the creation of the penny postage, and for his other reforms in the postal system of this country, the benefits of which have, however, not been confined to this country, but have extended over the civilised world."

In 1865, to his Imperial Majesty, Napoleon III., "for distinguished merit in promoting, in many ways, by his personal exertions, the international progress of Arts, Manufactures, and Commerce, the proofs of which are afforded by his judicious patronage of Art, his enlightened commercial policy, and especially by the abolition of passports in favour of British subjects."

In 1866, to Michael Faraday, D.C.L., F.R.S., "for discoveries in electricity, magnetism, and chemistry, which, in their relation to the industries of the world, have so largely promoted Arts, Manufactures, and Commerce."

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S., "in recognition of their joint labours in establishing the first electric telegraph."

In 1868, to Mr. (afterwards Sir) Joseph Whitworth, LL.D., F.R.S., "for the invention and manufacture of instruments of measurement and uniform standards, by which the production of machinery has been brought to a state of perfection hitherto unapproached, to the great advancement of Arts, Manufactures, and Commerce."

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, etc., "for his numerous valuable researches and writings, which have contributed most importantly to the development of food economy and agriculture, to the advancement of chemical science, and to the benefits derived from that science by Arts, Manufactures, and Commerce."

In 1870, to Vicomte Ferdinand de Lesseps, Member of the Institute of France, Hon. G.C.S.I., "for services rendered to Arts, Manufactures, and Commerce by the realisation of the Suez Canal."

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B., "for his important services in promoting Arts, Manufactures, and Commerce, especially in aiding the establishment and development of International Exhibitions, the Department of Science and Art, and the South Kensington Museum."

In 1872, to Mr. (afterwards Sir) Henry Bessemer, F.R.S., "for the eminent services rendered by him

Hosted by Google

to Arts, Manufactures, and Commerce in developing the manufacture of steel."

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France, "for his chemical researches, especially in reference to saponification, dyeing, agriculture, and natural history, which for more than half a century have exercised a wide influence on the industrial arts of the world."

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S., "for his researches in connection with the laws of heat, and the practical applications of them to furnaces used in the Arts; and for his improvements in the manufacture of iron; and generally for the services rendered by him in connection with economisation of fuel in its various applications to Manufactures and the Arts."

In 1875, to Michel Chevalier, "the distinguished French statesman, who, by his writings and persistent exertions, extending over many years, has rendered essential services in promoting Arts, Manufactures, and Commerce."

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal, "for eminent services rendered to Commerce by his researches in nautical astronomy and in magnetism, and by his improvements in the application of the mariner's compass to the navigation of iron ships."

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France, "the distinguished chemist, whose researches have exercised a very material influence on the advancement of the Industrial Arts."

In 1878, to Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S., "because of his distinction as an engineer and as a scientific man, and because by the development of the transmission of power—hydraulically—due to his constant efforts, extending over many years, the manufactures of this country have been greatly aided, and mechanical power beneficially substituted for most laborious and injurious manual labour."

In 1879, to Sir William Thomson (afterwards Lord Kelvin), O.M., LL.D., D.C.L., F.R.S., "on account of the signal service rendered to Arts, Manufactures, and Commerce by his electrical researches, especially with reference to the transmission of telegraphic messages over ocean cables."

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S., "for having established, after most laborious research, the true relation between heat, electricity, and mechanical work, thus affording to the engineer a sure guide in the application of science to industrial pursuits."

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry in the University of Berlin, "for eminent services rendered to the Industrial Arts by his investigations in organic chemistry, and for his successful labour in promoting the cultivation of chemical education and research in England."

In 1882, to Louis Pasteur, Member of the Institute of France, For. Memb. R.S., "for his researches in connection with fermentation, the preservation of wines, and the propagation of zymotic diseases in silkworms and domestic animals, whereby the arts of wine-making, silk production, and agriculture have been greatly benefited."

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S., "for the eminent services which, as a botanist and scientific traveller, and as Director of the National Botanical Department, he has rendered to the Arts, Manufactures, and Commerce by promoting an accurate knowledge of the floras and economic vegetable products of our several colonies and dependencies of the Empire."

In 1884, to Captain James Buchanan Eads, "the distinguished American engineer, whose works have been of such great service in improving the water communications of North America, and have thereby rendered valuable aid to the commerce of the world."

In 1885, to Mr. (afterwards Sir) Henry Doulton, "in recognition of the impulse given by him to the production of artistic pottery in this country."

In 1886, to Samuel Cunliffe Lister (afterwards Lord Masham), "for the services he has rendered to the textile industries, especially by the substitution of mechanical wool combing for hand combing, and by the introduction and development of a new industry—the utilisation of waste silk."

In 1887, to HER MAJESTY QUEEN VICTORIA, "in commemoration of the progress of Arts, Manufactures, and Commerce throughout the Empire during the fifty years of her reign."

In 1888, to Professor Hermann Louis Helmholtz, For. Memb. R.S., "in recognition of the value of his researches in various branches of science, and of their practical results upon music, painting, and the useful arts."

In 1889, to John Percy, LL.D., F.R.S., "for his achievements in promoting the Arts, Manufactures, and Commerce through the world-wide influence which his researches and writings have had upon the progress of the science and practice of metallurgy."

In 1890, to Dr. (afterwards Sir) William Henry Perkin, F.R.S., "for his discovery of the method of obtaining colouring matter from coal tar—a discovery which led to the establishment of a new and important industry, and to the utilisation of large quantities of a previously worthless material."

In 1891, to Sir Frederick Abel, Bart., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S., "in recognition of the manner in which he has promoted several important classes of the Arts and Manufactures, by the application of Chemical Science, and especially by his researches in the manufacture of iron and of steel; and also in acknowledgment of the great services he has rendered to the State in the provision of improved war material, and as Chemist to the War Department."

In 1892, to Thomas Alva Edison, "in recognition of the merits of his numerous and valuable inventions, especially his improvements in telegraphy,

Hosted by Google

in telephony, and in electric lighting, and for his discovery of a means of reproducing vocal sounds by the phonograph."

In 1893, to Sir John Bennet Lawes, Bart., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S., "for their joint services to scientific agriculture, and notably for the researches which, throughout a period of fifty years, have been carried on by them at the Experimental Farm, Rothamsted."

In 1894, to Sir Joseph (afterwards Lord) Lister, F.R.S., "for the discovery and establishment of the antiseptic method of treating wounds and injuries, by which not only has the art of surgery been greatly promoted, and human life saved in all parts of the world, but extensive industries have been created for the supply of materials required for carrying the treatment into effect."

In 1895, to Sir Isaac Lowthian Bell, Bart., F.R.S., "in recognition of the services he has rendered to Arts, Manufactures, and Commerce by his metallurgical researches and the resulting development of the iron and steel industries."

In 1896, to Professor David Edward Hughes, F.R.S., "in recognition of the services he has rendered to Arts, Manufactures, and Commerce by his numerous inventions in electricity and magnetism, especially the printing telegraph and the microphone."

In 1897, to George James Symons, F.R.S., "for the services he has rendered to the United Kingdom by affording to engineers engaged in the water-supply and the sewerage of towns a trustworthy basis for their work, by establishing and carrying on during nearly forty years systematic observations (now at over 3,000 stations) of the rainfall of the British Isles, and by recording, tabulating, and graphically indicating the results of these observations in the annual volumes published by himself."

In 1898, to Professor Robert Wilhelm Bunsen, M.D., For. Memb. R.S., "in recognition of his numerous and most valuable applications of Chemistry and Physics to the Arts and to Manufactures."

In 1899, to Sir William Crookes, F.R.S., "for his extensive and laborious researches in chemistry and in physics—researches which have, in many instances, developed into useful practical applications in the Arts and Manufactures."

In 1900, to Henry Wilde, F.R.S., "for the discovery and practical demonstration of the indefinite increase of the magnetic and electric forces from quantities indefinitely small—a discovery now used in all dynamo machines—and for its application to the production of the electric searchlight, and to the electro-deposition of metals from their solutions."

In 1901, to His Majesty King Edward VII., "in recognition of the aid rendered by His Majesty to Arts, Manufactures, and Commerce during thirty-eight years' Presidency of the Society of Arts, by undertaking the direction of important exhibitions in this country, and the executive control of British representation at International Exhibitions abroad, and also by many other services to the cause of British Industry."

In 1902, to Professor Alexander Graham Bell, "for his invention of the telephone."

In 1903, to Sir Charles Augustus Hartley, K.C.M.G., "in recognition of his services, extending over forty-four years, as Engineer to the International Commission of the Danube, which have resulted in the opening up of the navigation of that river to ships of all nations, and of his similar services, extending over twenty years, as British Commissioner on the International Technical Commission of the Suez Canal."

In 1904, to Walter Crane, "in recognition of the services he has rendered to Art and Industry by awakening popular interest in Decorative Art and Craftsmanship, and by promoting the recognition of English Art in the form most material to the commercial prosperity of the country."

In 1905, to Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S., "in recognition of the influence which his researches, directed to the increase of scientific knowledge, have had upon industrial progress, by facilitating, amongst other scientific applications, the provision of accurate electrical standards, the production of improved lenses, and the development of apparatus for sound signalling at sea."

In 1906, to Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S., "for the important part he took in the invention of the incandescent electric lamp, and for his invention of the carbon process of photographic printing."

In 1907, to the Earl of Cromer, G.C.B., O.M., G.C.M.G., K.C.S.I., C.I.E., "in recognition of his pre-eminent public services in Egypt, where he has imparted security to the relations of this country with the East, has established justice, restored order and prosperity, and, by the initiation of great works, has opened up new fields for enterprise."

In 1908, to Sir James Dewar, M.A., D.Sc., LL.D., F.R.S., "for his investigations into the liquefaction of gases and the properties of matter at low temperatures—investigations which have resulted in the production of the lowest temperatures yet reached, the use of vacuum vessels for thermal isolation, and the application of cooled charcoal to the separation of gaseous mixtures and to the production of high vacua."

In 1909, to Sir Andrew Noble, K.C.B., D.Sc., D.C.L., F.R.S., "in recognition of his long-continued and valuable researches into the nature and action of explosives, which have resulted in the great development and improvement of modern ordnance."

In 1910, to Madame Curie, "for the discovery of radium."

In 1911, to the Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S., "for his experimental researches into the laws governing the efficient action of steam in engines of the turbine type, and for his invention of the re-action type of steam turbine, and its practical application to the generation of electricity and other purposes."

PROCEEDINGS OF THE SOCIETY.

THIRTEENTH ORDINARY MEETING.

Wednesday, March 6th, 1912; JAMES SWINBURNE, F.R.S., M.Inst.C.E., Member of the Council of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Ainsworth, Herbert, P.O. Box 1553, Johannesburg, South Africa.

Andrews, Fred Henry, 3, Park-hill, Clapham, S.W.

Bishop, Albert E., 1, Metal Exchange Buildings, Whittington-avenue, E.C.

Dodge, Walter Phelps, The Reform Club, Pall Mall, S.W.

Kothari, Jehengir H., K.I.H., Karachi, India.

Millard, V. C. H., M.A., Shrewsbury House, Ditton-hill, Surrey.

Welch, George Winston, Danville, Kentucky, U.S.A.

The following candidates were balloted for and duly elected members of the Society:—

Bevington, Alexander, Silverwood, Pyrford, near Woking, Surrey.

Cadogan, Lieutenant Francis Charles, R.N., H.M.S. "Prince of Wales," c/o General Post Office, E.C.

Hussain, Moulvi Ahmed, C.S.I., M.A., B.L, Chief Secretary to H.H. the Nizam's Government, Hyderabad, Deccan, India.

Reinhold, Captain Carl Henry, I.M.S., F.R.C.S.E., 58th Rifles, F.F., Quetta, Baluchistan, India.

Scott, Charles, Rosedale, Bolivar County, Mississippi, U.S.A.

Singh, Baba Mihan, Small Cause Court, Amritsar, India.

The paper read was—

SOME MODERN PROBLEMS OF ILLUMINATION.

By T. THORNE BAKER, F.C.S., F.R.P.S.

During the past two or three years quite a large amount of attention has been paid to the subject of illumination, from more or less new points of view which have been suggested by modern conditions of living and working. Formerly it mattered little whether a candle, an oil lamp, or a Bray's gas-burner were responsible for the lighting of a room, provided only that the illumination were sufficient. Now we require an illumination which must possess the maximum economy, the maximum of diffusion and distribution, and which must be of a colour required by the dictates of hygiene. The means of testing an illuminant, of modifying its light so as to produce an illumination which is physically nearest to what is ideal from the point of view of hygiene, and so on, are few, and are appreciated by the few only who have made this subject a matter for personal attention. I propose to deal briefly to-night with simple ways and means of producing an illumination as nearly resembling daylight as possible, which can be adopted by illuminating engineers and others with a small amount of expense, and which will yet give results of sufficient accuracy to satisfy modern demands.

While so much attention is being paid to the subject of lighting, from hygienic and similar points of view, I think it seems fairly evident that its spectroscopic character should receive due consideration, but up to the present I do not think that the colour of light has been seriously dealt with by more than a few independent workers. We cannot, of course, compare the human body or the human eye with anything else, but it is interesting to note that the effect of colour on living organisms and on vegetable life is in some cases extremely marked. I have a slide here showing how certain bacteria crowd together in specific regions of the spectrum simply because these regions embrace the rays absorbed by the chlorophyll of the algal filaments present in the water, and, by the chemical change produced by this absorbed light energy, obtain the maximum of nutrition. I also showed a few months ago, at the Royal Institution, some remarkable effects of coloured light on the growth of bacteria, and more especially on the formation of pigment by bacteria, and on that occasion I stated the inference that one was led to arrive at—viz., that while the ultra-violet, violet, and orange rays produced marked effects on many families of bacteria, the green-yellow rays in the middle of the visible spectrum were usually without effect. I also showed, from tests made in the laboratory, how by projecting certain specified red rays into an experimental "vat" in which sugar was being fermented by yeast, alcohol was produced with abnormal celerity. A diagram of the apparatus employed is shown on the screen.

These facts tend to show that the artificial light employed for the habitation of human beings should presumably be that to which they are normally accustomed, viz., daylight, and I think that investigations made with a view to

Hosted by Google

determine the most suitable light for the eyes will lead to one result only—the demand for a light spectroscopically equivalent to normal daylight.

Whether normal daylight is the best illuminant or not may perhaps be open to argument, but it can hardly but be the case when we consider that man, through being accustomed to sunlight for so many thousands of years, must naturally have become physically adapted to it.

Except in isolated cases of specialisation, the illuminating engineer has not closely associated spectroscopic methods with the practical side of lighting and illuminant testing, though now much valuable work is being done by Dr. Ives and Mr. Luckiesh. I have come across many instances in this country where industrial work has been hampered through the use of artificial light, ideal, perhaps, from the engineer's point of view, but very deficient from the physicist's point. One example, of which there must be many hundreds of cases, was that of a factory where the printing of wallpapers was carried on. Considerable difficulty was always found, especially in winter-time, in the matching and choosing of colours, and it was found that, when the daylight was good enough, the colour matching—of the dyes, etc.—was done by it, whereas in dull weather it was carried out by the light obtained from carbon filament lamps. Considerable discrepancies naturally occurred from this practice, and a special lamp was made, in which I employed metal filament (tungsten) lamps, and a suitable light filter, which gave filtered light spectroscopically equivalent to daylight, so that uniform colour-matching and the accurate selection of dyes and pigments was ensured.

The spectrum of daylight itself varies within quite remarkable limits, as the slide now on the screen will show. You will see here the curves obtained by plotting against wave-lengths the densities obtained on a panchromatic plate on exposure in the spectrograph to sky-light at various times—dull evening summer sunlight, when by atmospheric refraction the light is very yellow, and sky-light with direct sunlight and with the sun obscured by light and heavy clouds respectively.

It is, I think, well agreed that the best standard to adopt is white cloud-light, and we may therefore direct the attempts under discussion to the screening of various forms of illuminants so that artificial illumination physically equivalent to daylight is obtained.

You will now see on the screen a natural colour photograph of the electric arc (open), which shows brightly recorded several of the principal lines. The positive pole has been touched with a solution of a lithium salt in order to give the orange and blue lithium lines, and the sodium lines and a few others are seen as well. Before dealing with the photo-spectrometric method, by which one illumination can be matched with another by a simple trial and error method, I will briefly discuss the analysis of illumination by spectro-photography. You see here two or three different forms of simple spectro-cameras for taking photographs of the spectrum given by the light of any illuminant which is focussed on the slit of the instrument. One of these is arranged with a quartz lens and a hand-feed arc lamp in the correct position for taking a photograph. Suppose, then, that we take a series of photographs on a very evenly sensitised panchromatic plate, of No. 1 illuminant, let us say, open arc, with uncored positive pencil, and then another series of No. 2 illuminant, let us say, carbon filament electric lamp or incandescent gas. On developing the plates under equal conditions, we get two sets of photographs of the spectrum of the two illuminants, and we can,

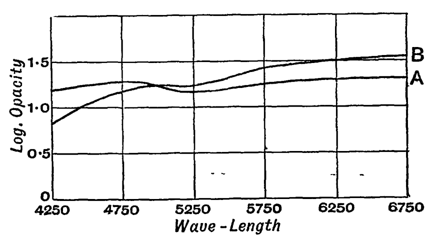

FIG. 1.—DENSITY CURVES OF (A) ARC, (B) TANTALUM LAMP.

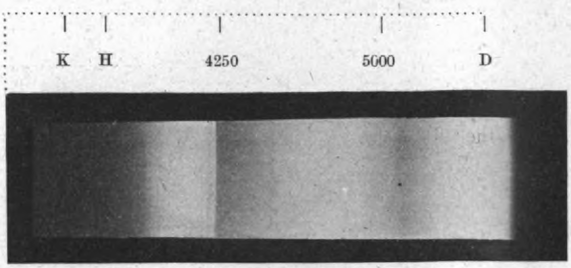
by comparing the most suitably exposed spectra in each, find with considerable accuracy the most obvious differences; the slide on the screen will show two such series of exposures, and it will be seen at a glance how relatively rich the arc light is in violet and blue, and how relatively rich the incandescent light is in greenish-yellow and red. A green object will look too bluish-green in the first light, and too yellowish-green in the second, speaking comparatively.

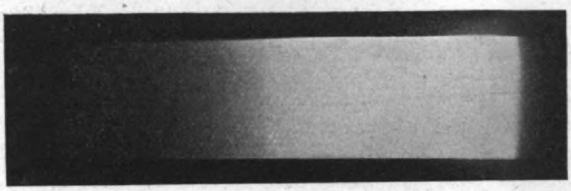
If now we divide these spectrum records into equal divisions, each division being a specific region of the visible spectrum, and measure with a suitable photometer the densities of these regions, and plot them against wave-length, we should obtain two curves which, when compared, indicate the relative spectroscopic character of the illuminants. The results are seen in Fig. 1.

Hosted by Google

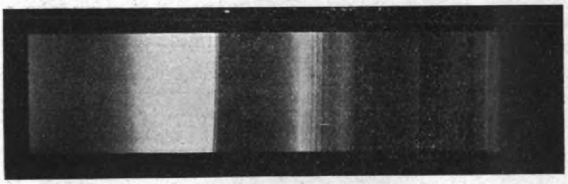
Spectrograph Prints illustrating the Remarks made in the Paper regarding Prism Records.



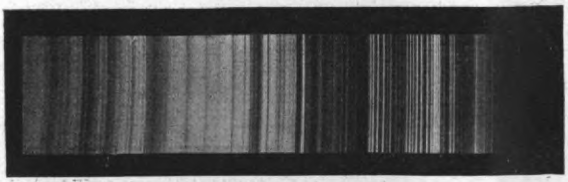
(1) Prismatic Spectrum. Open Arc.



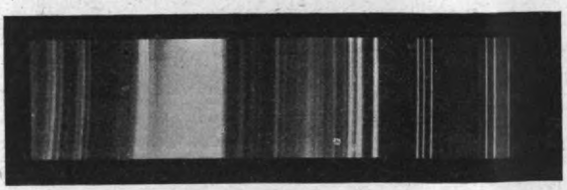
(2) Prismatic Spectrum. Carbon Filament Lamp.



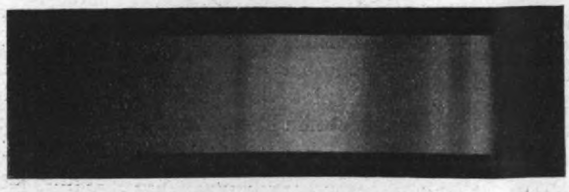
(3) Prismatic Spectrum. Purified Carbons.



(4) Vanadium Arc (Prismatic).



(5) Copper Arc (Prismatic).



(6) Daylight Spectrum (Prismatic).

These results give no definite measurements of the analysis of the illuminants, but they give all the indication requisite on which to base experiments for the production of a screening filter to render the screened illumination No. 2 identical with the illumination No. 1. It is clear that, as No. 2 is deficient in violet, blue, and blue-green, for example, the screen must be blue-violet and slightly green, in order to absorb the over-strong yellow and red rays. After making a liquid filter of this colour and testing the illuminant again with the spectrograph, we shall see how much nearer we have got No. 2 to No. 1. A series of experiments will give the necessary results, and we shall finally, on testing, find the spectra given by arc light and the *screened* incandescent lamp identical. Such a result is now shown on the screen.

This spectrographic method is useful in many ways, and I shall therefore devote a little time, with your permission, to refer to actual apparatus. The most suitable apparatus for this type of light analysis is unquestionably the concave grating spectrograph, as the dispersion throughout the spectrum is proportional to the wave-length. In the prismatic spectrum the ultra-violet and violet-blue regions are well dispersed, whereas the green, yellow, and red regions are all cramped up together, and therefore tend to appear far more luminous than actual measurement shows them to be. Some examples of the use of the prism spectrograph, which I will now show, give a very good idea of the erroneous indications of those records, though the abnormal density in the yellow-red region is to some extent in accordance with the character of the usual direct luminosity curves of the spectrum—not of the logarithmic curves as obtained with the spectrophotometer. The first two slides show respectively prismatic records of the open arc and a carbon filament incandescent lamp. The bands and lines in the former are seen to predominate and appear in an otherwise continuous spectrum, while the excessive amount of yellow and red rays are shown up well in the latter.

Hosted by Google

A third slide (3) shows the line spectrum of the positive pole of an arc between purified carbons. The carbon pencils were soaked in pure nitric acid for two weeks, and then in several changes or distilled water for several weeks. The fourth and fifth slides of this series show the spectrum with carbons rendered impure with (4) vanadium chloride; (5) copper chloride, and indicate the importance of pure carbons when screening the arc light in order to minimise the line effect. The sixth slide (6) shows a prismatic spectrogram of daylight, in which the principal Fraunhofer lines are seen.

A diffraction grating illuminated with parallel rays normal to itself gives us for light of any wave-length λ the expression

$$n \lambda = b \sin n \theta,$$

where n is the order of the spectrum, b the width of the rulings of the grating, and θ the angle the viewing telescope makes with the normal, when the line of the wave-length in question occupies the central position of the eyepiece field. Since the first order spectrum is usually employed, we have $\lambda = b \sin \theta$.

Plane grating replicas with about 17,000 lines to the inch are obtainable now of great precision, and more recently concave gratings have been made with success by mounting a celluloid replica on curved speculum metal. The great advantage of the concave grating is that it acts as its own lens, and no lenses are therefore necessary in the camera. Thus the difficulties of selective absorption before the light reaches the plate are obviated. You will see here a small concave grating camera, designed by Mr. Sanger-Shepherd, which will give a 3-inch spectrum of extremely fine definition. If we use a quartz lens for projecting the image of the illuminant on the slit, we can obtain the ultra-violet and blue-violet spectrum, and, by altering set screws at the back of the camera, the grating can be reset for photographing the visible spectrum only. The slide on the screen shows a simple line spectrum (copper and sodium) which is suitable for scaling. One inch on the actual negative represents approximately 1,250 Angström units, and as the dispersion throughout it is proportional to the wave-length, if we have one known line as a datum line, the spectrum can be divided up immediately into specific regions by simple measurement.

For more critical work, a camera attachment to a spectrometer is very useful, and I have here a small spectrometer fitted up in this way with which much of my own experimental work is done. The photographic plate admits of a 2-inch spectrum only, but with a 2-inch dense flint prism a 6-inch spectrum is obtainable, so that we can deal with the spectrum in three separate parts. An Iceland spar or quartz prism (with a corresponding change of course in collimating and telescope lenses) enables us to photograph the ultra-violet region. Very fine definition can be obtained in this way, which is equal to that of far more costly apparatus, while one has the advantage of being able at a moment's notice to remove the camera and place the eyepiece in the telescope for visual work, which, by the way, is frequently required.

Where a prism is employed, it is necessary to prepare a scale from which every desired wave-length can be easily found from its position on the negative. A number of known lines are obtained from either the arc or the oscillating spark from an induction coil with a capacity shunted across the spark-gap. The positions of these lines are then accurately measured with a travelling microscope and plotted against wave-length on squared paper, and the necessary reference curve prepared. By using a flat grating instead of the prism, the dispersion is once again obtained nearly proportional to the wave-length, so that scaling becomes easier. A screen is usually necessary to cut out the ultra-violet portion of the second order spectrum.

It is, of course, open to argument whether a purely photographic method of analysis is preferable to a visual method, but if the tests are carried out in a suitable way, it is, I think, a very satisfactory one. Standard negatives of a standard illuminant, however, cannot be obtained with any great precision unless the most rigid precautions are observed, and a fresh control negative is always desirable with which to compare the negative made with the illumination under consideration. A very evenly colour-sensitised plate is essential, and I know of none better for the purpose than the new Ilford panchromatic, which gives, with the open arc spectrum, an almost uniform deposit throughout. Ordinary plates bathed in a 1:100,000 solution of homocol, containing 2 per cent. of ammonia, also give even colour sensitiveness, but bathing is a troublesome process, and it is, therefore, far preferable to obtain the plates already bathed.

Before leaving this section of the subject, I will show one or two spectrograms made with the spectrometer with camera attachment. The first is of mercury vapour, in which the prominent mercury lines are clearly shown; the second is of neon, to which I shall refer again later.

Hosted by Google

The third is a spark spectrum, such as serves for scaling purposes, obtained by focussing on the spectroscope slit the oscillating spark of a 2-inch coil with one quart Leyden jar shunted across the spark gap. By using lead for one electrode and copper for the other, moistened with a solution of lithium chloride, we get several known lines well distributed throughout the spectrum, from which a scale can be readily made.

Dr. Eder has kindly sent me some of his most recent spectrograms, taken with the well-known grating spectrograph in Vienna, and as these are closely connected with the metal filament lamp industry, I am glad to be able to show them to-night. They are as follows:—

1. Erbium nitrate (visible and ultra-violet).
2. Vanadium nitrate (visible and ultra-violet).

(This should find extensive application for arc carbon cores.)

3. Niobium (visible and ultra-violet).
4. Tantalum (visible and ultra-violet).

Apart from the rough qualitative method of comparing two illuminants by having their spectra thrown into juxtaposition with a spectroscope fitted with a comparison prism, the most direct analysis of illumination is by means of the spectro-photometer, an instrument of which there are now several types to be had. Two beams of light can be examined simultaneously, either by the aid of a comparison prism on the slit of the spectroscope, or by means of a prismatic separator such as is used in the Hüfner instruments. One of these beams may be that of a standard light, the other that of the light to be compared with the standard, whilst either one or the other beam may be dimmed by the use of crossed Nicol prisms.

In Dr. H. E. Ives's work, the spectro-photometer has been largely used, and he has dealt in a very practical way with methods of comparing and standardising with daylight various illuminants. He suggests the use of coloured pot-glass, with a supplementary dyed filter to compensate for any narrow absorption bands, as a means of making a filter to produce light spectroscopically equal to daylight; but I do not think this is as practicable as the method of using dyed gelatine by itself, or dyed agar-agar where the heat would be likely to upset a gelatine film. Various useful curves and data obtained by Dr. Ives have been recently published in the *Illuminating Engineer*, and much practical suggestion as to methods of making light filters.

The spectro-photometer (a diagram of Messrs. Hilger's Hüfner apparatus is shown in Fig. 2), gives direct readings of the relative

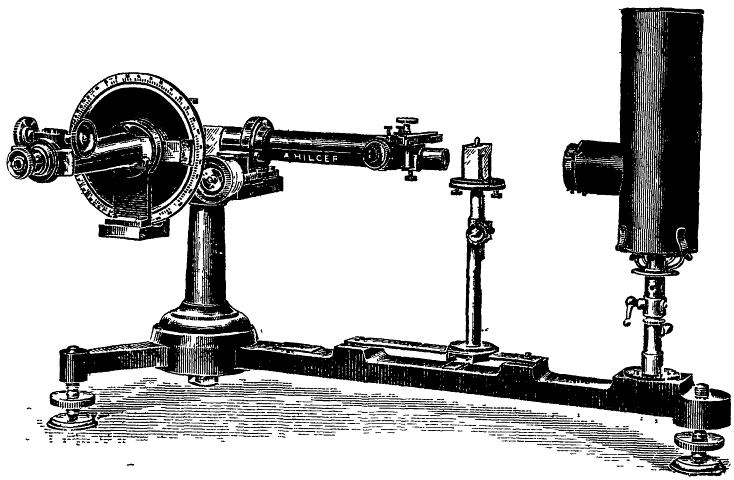


FIG. 2.

intensity of two light sources, which can be measured in successive regions of the spectrum by means of a slit shutter, which screens off all but the region under comparison. The standard beam passes through a Nicol prism, which polarises the light perpendicularly, and it and the beam whose spectrum is to be measured are then thrown on the slit of the spectroscope, so that their spectra are seen in juxtaposition in the eyepiece. The intensity of the spectrum under examination is readily deduced by rotating a second Nicol prism, which extinguishes the standard beam to the desired amount—*i.e.*, until for the narrow region under comparison the two are of equal visual luminosity; the square of the cosine of the angle of rotation of the second Nicol gives the density required.

The Hüfner instrument comprises one of the

Hosted by Google

Hilger constant deviation spectrometers, one of which I have here on the lecture table, and those gentlemen who care to examine the helium and neon lines afterwards will, I trust, do so, especially as, through the kindness of Professor

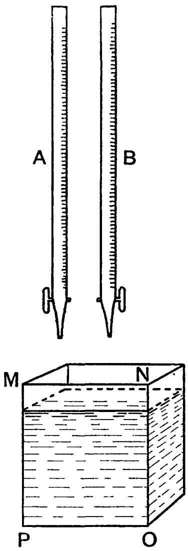

FIG. 3.

Fleming, I am able to show one of the very fine neon tubes made by him at University College. These tubes are of great use in radio-telegraphic measurements, as they are readily excited by high-frequency oscillations, and the nodes and antinodes of the waves produced in antennæ, or the long inductance coils in which stationary oscillations are set up, can be located with accuracy for wave-length determination.

A simple spectro-photometer can be made by employing two Nicol prisms with an ordinary spectrometer fitted with a comparison prism, the polarising Nicol being placed in the optic axis of the standard beam, and the analyser being substituted for the spectroscope eye-piece. If an analyser with a large divided circle be employed, the measurements can be made with a good deal of accuracy. These sets of polariser and analyser are quite inexpensive, and the latter is fitted with a divided drum in many of the sets designed for food analysis. By making an adapting collar, they can easily be fitted to the spectrometer telescope in place of the usual eyepiece. The polariser is merely supported in a stand to lie in the optic axis of the collimator.

A convenient apparatus for the production of a "daylight" or other filter is that shown in Fig. 3. Here *A* and *B* are two burettes (and there may be any number of them) filled with solutions of dyes of known strengths, let us say, 1 per cent. The glass cell through which the rays from the illuminant are screened before falling on the spectroscope slit, is filled with water, the area of which, *MNOP*, is, say, x square centimetres. Trial and error experiments show us that y cubic cm. of the solution in burette *A*, and z cubic cm. of that in burette *B*, give the desired tint to the liquid filter—*i.e.*, colour it so that a beam of light passed through it to the spectrograph or spectro-photometer shows it equal colorimetrically to daylight. We then know that, to prepare a daylight filter for the lamp tested, we require for each square centimetre of surface—

$\frac{y}{100\,x}$ grms. of the dye present in burette A,

$\frac{z}{100\,x}$ grms. of the dye present in burette B,

and so on.

Where light filters are to be prepared on a large scale, pot-fired glass would, of course, be ideal; but if ventilation can be secured, and the filter need not become too hot, a gelatine solution (about 8 per cent. strength), with the necessary dyes incorporated, can be coated on flat rolled plate-glass, the requisite amount of coloured solution being allowed per unit area. The next slide (Fig. 4) shows a contrivance I have made in several instances for industrial work where colour mixing or matching is part of the ordinary routine, with the result that in all weathers, and by day or night, one has standard daylight illumination to work by. A number of metal filament lamps (usually tungsten) are fixed in

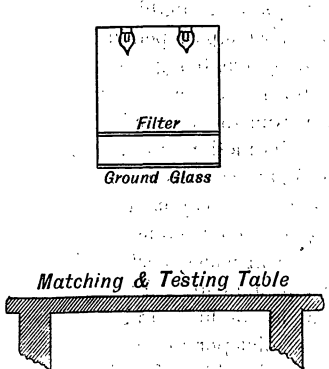

FIG. 4.

the top of a metal box, the top and inside of which is enamelled white. Below them is the gelatine-glass filter prepared in the manner described, from either spectro-photometric or spectro-graphic tests, and below that is a piece

of ground glass to diffuse the rays. The ground glass, by the way, has itself a slight screening effect which has to be taken into consideration. Rays of white "daylight" are then thrown down on the table where the colour-matching is done.

Now, if we were to take ourselves to task systematically, and apply to inverted lights these daylight filters, it would be possible to flood our art galleries and picture exhibitions with natural, normal light, and to place them at the disposal of the public for many more hours a day than we can do at present. Artificial daylight, so essential for the exhibition of pictures, could be obtained not only at night, when there is no real daylight, but at any time of the day in dull weather. The cost is by no means prohibitive. I estimate that to screen tungsten filament light to simulate normal daylight, only a small percentage (two or three)* of it is wasted in absorption by the screening filter, and if these filters were taken seriously in hand by illuminating engineers, we should soon be able to have the light of maximum hygienic properties in all the commercially applicable forms. So much excellent work has been done by electrical engineers in recent years, and so much time and thought spent in producing well-diffused illumination, that it seems a pity to stop short of rendering the light approximately identical with daylight, so that it could be a satisfactory substitute for it.

We come next to sources of illumination provided by the discharge of high-tension currents through vapour or rarefied gases. The mercury vapour lamp is now too well known to need any description, but the Moore and Cooper-Hewitt lamps are probably only the forerunners of many other lamps depending on the luminosity of electrically excited gases, notably neon and helium, both rare gases which can now be extracted from the atmosphere on a commercial scale. A distinction must, of course, be drawn between light produced by incandescent and by arc lamps and vapour tubes, for whereas the former give a continuous spectrum, the latter give spectra in which certain lines or bands or both are prominent. Arc light thus contains several series of lines and bands in the violet and ultra-violet portion of its spectrum, due to cyanogen and oxides of carbon, etc., as well as others in the green, due to nitrogen, etc., and so on. These lines mean that although we appear to have a fairly normal spectrum, we are really letting our eyes be subjected to an excess of certain more or less harmful rays in addition. If many of these rays be isolated, they can be used for bactericidal and therapeutic purposes. Similarly, if a mercury vapour lamp be used with quartz glass, its rays include those in its spectrum which are bactericidal. If, then, we accept normal daylight as the ideal, it is unlikely that we shall ever match it with the illumination from a vapour lamp, though it must be remembered that the sun's spectrum contains, amongst its many thousands of lines, some which are far more marked as regards luminosity than others, or, more correctly, many spaces lighter than the normal between dark lines or series of lines.

The slide next on the screen shows spectrum photographs of a mercury vapour light, and under it the spectra of neon and helium. It will be seen what a number of bright and well-defined lines each one possesses. It is also seen to what an extent the bright green mercury line, which is largely used in physical work as a source of monochromatic light, accounts for the illumination. Similarly, we see the nature of the predominant yellow and red lines in the spectrum of neon. The dielectric strength of neon is about one seventy-seventh that of air—*i.e.*, about seventy-seven times the voltage would be required to break across an air gap as would be necessary in the case of neon. Pure neon is exceedingly luminous when subjected to high-tension discharges, and is likely to prove very efficient as a source of illumination. Some interesting particulars were recently published in *The Electrical Review*, where an abstract of a recent paper by M. Claude was given. Neon is not apparently so scarce as one was originally led to believe, for M. Claude claims to be able to produce as much as one hundred litres of neon in a day, which suffice for the manufacture of one thousand tubes of one thousand candle-power each. The tubes at present made for commercial purposes must be supplied with alternating current, and 3,200 volts is stated to suffice for lighting three tubes in series each six metres in length. The lighting power is about two hundred candles per metre of tube, and the consumption for the luminous portion of the tube is about 0·45 watt per candle.

I have here a small neon tube, from which you will see the colour of the light emitted, as against the helium tube. The rays are a rich golden red, and I believe that, if they were mixed with those from a separate mercury vapour tube, the combined illumination would be very much better than that of either separately. I venture

* In the case of the open arc.

Hosted by Google

to predict that by combining tubes in series or in parallel, each filled with a different gas, a combined spectrum will be reached which will be most close to the ideal requirements, and far closer than illumination already obtained tentatively by combining incandescent electric lamps with mercury vapour. I fancy that this method will be better and more economical than the screening of the lamps or the use of fluorescent reflectors. While on this subject, I will take the opportunity of showing the value of the fluorescent reflector which has been produced after so much experiment for the Cooper-Hewitt lamp. You will see by examining the colours on this chart, when it is illuminated by the ordinary mercury vapour lamp, and then by comparing them when it is illuminated with the lamp with the reflector attached, how much nearer the real thing the latter light is. I have only been able to make a limited number of tests with combined spectrum tubes in the laboratory, but from these experiments it appears feasible, by employing two tubes simultaneously whose spectra are in some measure complementary, to obtain a more or less white illumination. A direct confirmation of this will be seen later when dealing with helium light.

A point of interest is that a good deal of a neon or helium vapour tube is useless for purposes of illumination—the portions near the electrodes —and in the case of Claude's neon tubes one metre is non-luminous in a six-metre tube, or one-sixth of the total. The non-luminous portions contain, as a rule, complex spectra entirely different from that of the visually luminous portion, and their ratio to that of the luminous portion becomes less the more we increase the length of tube; hence very long tubes are more efficient for lighting than short ones.

Turning now to helium, we find a gas which offers many attractions both for investigation and for practical use. Rarefied pure helium gas gives an intense light of whitish-yellow hue, somewhat similar to that of the flame of some of the lighter burning oils, and yet spectroscopically it consists merely of a few isolated bright lines, notably two in the red, one in the yellow, one in the green, and two in the blue-violet regions.

These lines are of such wave-length that in combination they present a light which it is difficult to believe does not possess a continuous spectrum. I have here a helium tube, and will show it illuminated by a small induction coil, and you will see what a beautiful quality the light possesses. Despite its apparent whiteness, the spectrogram shows how isolated the component lines are, and yet how evenly distributed throughout the visible spectrum. The yellow line is double, but is so relatively bright that it appears merely as one broad line.

Helium vapour lamps have quite recently been adopted by the Bureau of Standards at Washington as the standard unit of illumination, and one very important point in favour of this choice is the fact that the luminosity of the tube remains constant over quite a wide range of current. It is naturally a great advantage to the observer if a 5 per cent. increase in the current supply of the standard lamp causes no variation in its candle-power. But the apparent colour of the light renders it extremely suitable for comparative purposes, as it is a more or less "happy medium" of paraffin oil gas, flame gas, incandescent gas, and metal filament lamps. For an unfiltered light the open electric arc and the acetylene flame are the nearest approaches

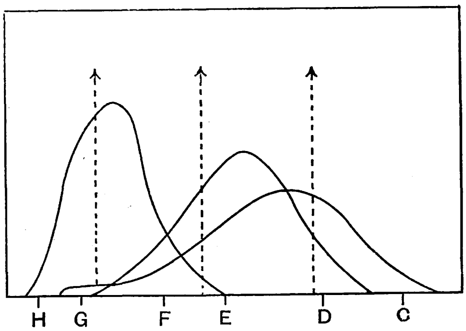

FIG. 5.

to daylight, but, owing to the constancy of the candle-power under varying circumstances of the helium vapour lamp, the latter should prove ideal as a standard light source.

An interesting problem crops up in relation to helium light, which I believe is likely to play an important part in the lighting of the future. Assuming that we are agreed as to the desirability of having a white illumination resembling normal daylight, what will be the effect of having a light white only in appearance, and not actually the result of a continuous spectrum? I have drawn on squared paper an approximate reproduction of Clerk-Maxwell's curves, showing the spectra included by the three primary colours, and have drawn in the position of the brightest helium lines (Fig. 5). You will see at a glance that they occupy positions more or less centrally situated near the maximum of these three curves, one just to the less refrangible side of the *G* line,

Hosted by Google

one between F and E, and one slightly more refrangible than the D lines. It is thus quite clear why we get such an apparently pure white light, as by mixing light of the wave-lengths of the maxima of the three curves we should have an apparently pure white light.

The question then comes: Is a white light, due to the mixing of light of three or more wave-lengths, of equal value from a hygienic point of view to white light due to a continuous spectrum? On the assumption that colour vision depends on the actuation of three nerves only, each corresponding to one primary colour, it does not seem unreasonable; yet it is well known that narrowly-defined regions of the spectrum alone have definite therapeutic effects.

I cannot on the present occasion attempt any answer to this interesting problem; the only experiments I have made have been the subjection of bacteria to light of isolated wave-lengths—*e.g.*, the green mercury line and the monochromatic light from a sodium lamp, and no positive results were obtained. There may be some present, however, who can throw some light on the matter, which is one that demands close attention, as since from the efficiency point of view vapour lamps would appear to hold the prospective field, I certainly think the characteristics of helium vapour suggest it as the light of the future.

A helium vacuum tube 7 cm. in length and 2 mm. in bore, with terminal bulbs containing aluminium electrodes 25 mm. in diameter, has been, I believe, decided upon as the standard by the Washington Bureau. The light is found to be constant even over a considerable range of voltage and current frequency, as stated above.

In connection with vapour tubes, several points have to be borne in mind when making any experimental measurement of efficiency. The colour of the luminous discharge of electrons, of course, varies with the degree of exhaustion, and up to a certain point an increase in the exhaustion means decrease in the potential necessary to cause the discharge. Under certain conditions there is definite proof that the colour of the emitted light is partially, though not largely, due to the material of which the electrodes are made, spectrograms having been obtained from vapour discharges, which include lines due to the electrodes. The colour of the glass has a very important effect on the character of the light, owing to the fluorescence of certain types of glass, and a very simple experiment (which I trust the more technically-minded will excuse) shows the two-fold effect of a discharge through rarefied air,

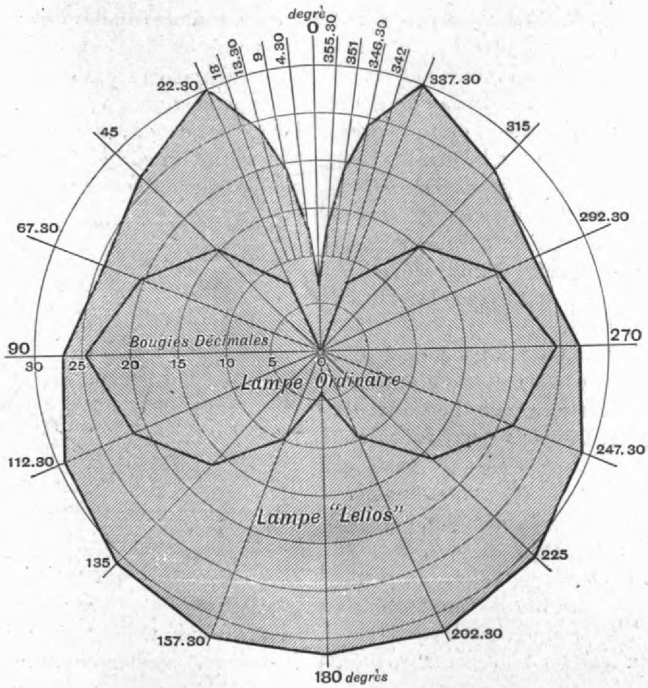

Fig. 6.

Hosted by Google

the tubes in one direction being of a different glass from those in the direction at right angles.

I believe that there will be room for great experiment in determining the character of suitable glass for the manufacture of the vapour lamps which are likely to be exploited in the future, and it is fairly obvious that this character will vary according to the vapour being employed.

One of the most important lessons of the helium tube is that, in endeavouring to secure white illumination, an easily obtained isolated spectrum line may do more good than any amount of wide continuous or banded regions.

One feature with which illuminating engineers will have to deal is the effect of the character of the current supplying vapour tubes on the colour of the luminous discharge. It is well a rectifier), it gives a distinct yellow light when used on a high-frequency oscillating circuit.

The commercial neon tubes of Claude, when run on alternating current, can be controlled by means of a series inductance, and the current can be reduced from the normal, about 1·3 amperes, to 0·6 amperes. Here, again, it is observed that the light becomes red with decrease in the current consumption, due to the attenuation or even wiping out of the more refrangible spectrum lines.

There are one or two points of interest I should like to draw your attention to before concluding to-night, in reference to some new work in connection with light distribution. One is a new lamp which emanates from Brussels, in which the (metal) filaments are suspended in a horizontal

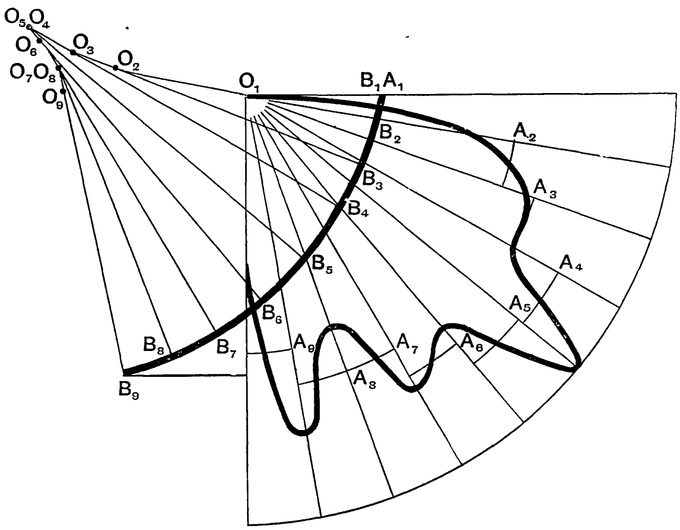

FIG. 7.

known how the spectrum of an oscillatory spark changes when self-induction is introduced into the oscillating circuit, and both self-induction and capacity appear to affect neon and helium tubes. When illuminating the tubes by means of high-frequency oscillatory currents, the higher the frequency the less is there of the violet components in the spectrum of the gas. Thus, while neon emits a good golden light in the ordinary way, the tube being fed from an induction coil, if we feed it with oscillatory currents, the colour becomes a dull red, and the higher the frequency the duller the colour—*i.e.*, the more pronounced are the lines in the red part of the spectrum, compared with the blue-violet, etc. The same is the case with helium, as I shall be able to show. While it emits a beautiful white light with direct current (I am using, as you see, position across a square frame of glass tubing. This frame itself is suspended to a spring attachment which forms the top of the lamp, and reduces vibration effects considerably. The chief feature of the lamp, however, is its downward and uniform illumination. The light distribution is seen in comparison with that of a vertical filament lamp in the diagram shown on the screen (Fig. 6).

Through the courtesy of Professor Fleming, I am also able to show to-night some curves which have just been made of the peculiar variation in the field of illumination of flame arc lamps, and the effect of a reflector on the field. These measurements have been made at the Pender Laboratory with their large photometer by Mr. W. C. Clinton, the arc lamp being displaceable in horizontal and vertical directions to admit of

Hosted by Google

exploring the illuminating power in different directions, according to the method of Dr. Kennelly. The very erratic distribution of the light is shown by the first three curves (Fig. 7), and though the extraordinary irregularity of the light intensity at different angles was at first thought to be perhaps due to errors of observation, further tests have fully confirmed the measurements. The evening-up of the illumination curve into a more or less symmetrical one, by means of a globe and reflector, is well shown by the last diagram (Fig. 8).

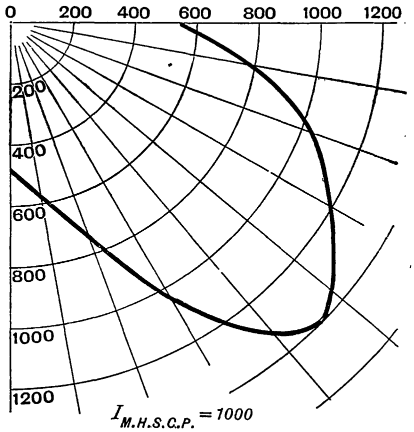

FIG. 8.

In conclusion, I trust that those present who are actively interested in illuminating engineering will forgive me if I appear to have trespassed too much on their province on the plea of spectroscopic methods, but modern education is causing many demands to be made with which the electrical profession were not faced even a year or two back, and, quite apart from the question of the ideal light for hygienic needs, there certainly is room for the introduction of "standard daylight" in the laboratories and testing-rooms of hundreds of industrial factories in this country, and for the greater utility of many of our public museums and galleries.

DISCUSSION.

MR. A. P. TROTTER, in opening the discussion, said the paper was full of most important and interesting observations, and would amply repay study by those who were engaged in some of the subjects with which it dealt. The author almost apologised for saying that the spectroscope must be used for such investigations as he had mentioned, but there was no need for such an apology, as it certainly must be used; because, for instance, the visual white light might be produced, as the author had shown, by three or four mono-chromatic bands in the spectrum, and when colour matching had to be dealt with a great deal better light than that was necessary. In that connection, however, the author suggested the very interesting point that if a combination of Maxwell's three fundamental colours was made, it was possible that that would be equivalent to a white light. That was a matter for experiment, not by one man only, but by various people, because the eyesight of people who might be described as having normally good colour vision differed very much. In colorimetry as practised in biological chemistry, where, for instance, the colour of blood was matched against carmine, one man might get a perfect match under certain circumstances, while other people would totally disagree with him. In colour matching, the whole of the spectrum had to be considered. The paper particularly interested him because he had been spending some time lately trying to get artificial daylight. He thought the time had come when, for certain purposes, especially in artists' studios, picture galleries, and many industries, good artificial daylight ought to be obtainable. Some twenty-three years ago he had described in a paper on the arc lamp the spectrum which was necessary for that; that was to say, he took Abney's spectrum of daylight and of the arc lamp and of the gas lamp, and showed what had to be done in order to produce artificial daylight. All artificial lights at present in existence were too rich in yellow and red, and those two colours had to be absorbed. As far as his experiments went he could not hope for such a small loss as 2 or 3 per cent., which the author mentioned. Dr. Mees had produced a filter which was photographically correct —a very different thing—and that gentleman only got 15 per cent. of his light through. But, for the purposes of artists and picture galleries, and many other purposes, it was not necessary to be photographically correct, and it was easy enough to get white light. He (Mr. Trotter) had at home a box full of daylight, apparently white light, and he had asked Messrs. Powells, the glass-makers, to supply him with different samples of blue glass. The first samples were of cobalt glass. As the author pointed out, it was not difficult to get a perfect match with daylight, but daylight was continually varying, and artists were apparently satisfied with the white daylight obtained on a grey day. A grey day was an ideal day for an artist, but Nature could not hold on in that respect for more than an hour or so, and the light varied from hour to hour. The cobalt glass was hardly any good, because although it was apparently a perfect white light, if it was examined through the spectroscope it would be found that it had four marked bands. He was trying other kinds of blue glass. One had to get a perfectly smooth spectrum, and that was a matter which could only be tried with a spectroscope and with spectro-

Hosted by Google

photometry; and the information which the paper contained ought to be of the greatest use to those who were working in that subject. The author had thrown the tantalum spectrum on the screen, and had said that it was of interest at the present time because the tantalum lamps were being used. He (Mr. Trotter) did not quite see the connection, because that was the tantalum arc spectrum, and an ordinary tantalum lamp gave an incandescent spectrum. Was there any relation between the spectrum and the tantalum glow lamp—any selective emissivity having relation to its arc spectrum?

Mr. Leon Gaster thought that the Society ought to congratulate the author on his very interesting paper. He, however, desired to point out that Mr. Thorne Baker seemed to be acquainted with what had been done up to a certain period only. He had asked illuminating engineers to take notice of what had been done with regard to spectroscopic work and so on, but did not mention an interesting meeting of the Illuminating Engineering Society held in that very room about two months ago, when Mr. Ritchie had dealt with the subject of discrimination of colour by artificial light in a most up to date way. With regard to the manufacture of daylight, he could not agree with the author's optimistic figure of a loss of only 2 or 3 per cent.; this, as Mr. Trotter said, was quite at variance with the experience of Dr. Mees, who had actually shown a lamp of this kind on the night of Mr. Ritchie's paper. Moreover, no variety of "white light" which had gaps in its spectrum could reveal colours quite exactly as the author seemed to suggest.

Dr. F. W. Edridge-Green said the point at which illuminating engineers were trying to arrive at the present time was a very important one indeed, namely, how a light which was visually similar to daylight was to be obtained. There were two different methods which had to be taken into consideration. One appeared to give an effect which was a photo-chemical effect and corresponded more to the upper end of the spectrum; and the other appeared to give a visually stimulating effect which corresponded to the lower end of the spectrum. It was well known that the red light was the best for seeing at night, but it would be noticed that when the light was reduced the redness would disappear. The point to which he especially wished to allude with regard to matching daylight by artificial light was in connection with the three curves of Maxwell which had been thrown on to the screen. If any three points of the spectrum were taken, it would be found that they did not in any way correspond visually to white light; it was an absolutely different thing altogether. He would mention one or two simple examples which the members could try for themselves. One could undoubtedly make a more or less yellow colour by mixing, say, red and green, but if that yellow colour was shown to half a dozen people it would probably be found that they all differed and that perhaps only one would be satisfied that it was a match; one person would be clear it was green, and another person would be clear it was red. One way by which it could easily be seen that yellow was quite a simple sensation and not a compound sensation of red and green, was that yellow would not fatigue the eye for either red or green. Another very simple method by which it could be proved that yellow was a simple sensation was as follows. One could fatigue one's eye for green. For instance, one could put on blue-green spectacles which absolutely cut off the red, and then if one looked at the spectrum it would be found that one could pick out the yellow exactly at the same spot as one would do if the eye were not fatigued. If the whole of the series were in any shape or sense true, when the eye was fatigued for green, one would go right away up into the green—that was to say, the yellow junction would be shifted, but it could be picked out by means of shutters, such as existed in his spectrometer, exactly in the same wave-length. That showed the yellow was a simple and not a compound sensation. Therefore the point which he thought illuminating engineers should aim at was either to dull down the continuous spectrum or to form a spectrum which contained all the rays as nearly as possible to make an artificial daylight.

Mr. Thomas E. Ritchie remarked that the author had mentioned the importance of pure carbons, and he, the speaker, quite agreed with him in that statement. It was of supreme importance that the carbons used in an arc should be of the very greatest purity, but he immediately joined issue with the author as to the purity of the carbons used in obtaining the arc spectra which had been exhibited. From the appearance of the blue-violet end, he thought the author had failed to practise what he preached in that particular respect. He did not think that the spectra indicated anything like what could be got from pure carbons, which were obtainable without difficulty if they were required. He would like the author to give some information as to the percentage accuracy of the filter built by him, for which he claimed such a miraculously low absorption factor. No information had been given as to its percentage colour compared colour by colour right through the spectrum. He had been particularly interested in the author's remarks as to the variation of the spectrum of the neon tube, with the alteration in the periodicity. It perfectly agreed with that of the ordinary open arc, which also varied in much the same way. He should also like to inquire if the author's filter had been in existence for a sufficient length of time to enable Mr. Baker to furnish any information as to its permanency. That was a very important point in Dr. Mees's experiments—the investigation had been very thorough, and it was known with reasonable certainty that the filter, as it was now being made, was permanent, which, after all, was the great

Hosted by Google

thing. The efficiency was not of so much moment as compared with the permanency. He should also like to ask the author whether, with the concave grating he had used, he had been able to obtain in the Sanger-Shepherd camera anything in the nature of spectrographs taken by reflected daylight, and reflected artificial light.

Mr. J. S. Dow said he strongly felt that, in testing the effect of illuminants on colours, it was not enough, however skilful one might be, to make photographic tests alone, and one of the features of Mr. Ritchie's researches was that he not only did the photographic tests, but he also made an analysis of the colours of a series of ribbons by the tintometer apparatus, and tabulated photometric and visual effects in conjunction with those data. One point which the author might have mentioned was the important effect of colour on the efficiency of the illuminant. It was estimated that if white light only was produced in the spectrum 26 candle-power per watt would be produced, whereas, if a green-yellow ray only was selected, as much as 50 candle-power per watt would be obtained. The most efficient lamp at present available probably did not give more than about 5 candle-power per watt. Mr. Ives had been led recently to suggest a standard of light based on the green mercury line only, but he (the speaker) thought that standard, and also the helium standard experimented with at the Bureau of Standards, was open to the objection that the physiological difficulties of comparing lights so very different from a true white light were very serious, probably so serious as to do away with the advantage of any improvement in the physical control of the lamp. And Dr. Edridge-Green had proved the complexity of the retina when one came to compare such illuminations; the Bureau of Standards had not decided to adopt the Helium standard, which was only in the experimental state as yet. With regard to the mixture of red and green lights to make an apparent white light, there was no question, he thought, that a white light made in that way would give quite different results from a genuine white light when one came to compare different colours. He (the speaker) remembered a very interesting series of researches in which a microscopic investigation was made of the wing of a butterfly, and the experimenters came to the conclusion that the colour of those particles was due to the fact that their diameter was in the neighbourhood of the respective wave-length of light; and that the colours of objects in general were due to the fact that they were of a size to resonate with certain wave-lengths of light reaching them. Perhaps the author would express his opinion on the validity of that theory.

Mr. E. P. Hollis said he noticed that when the author wanted to make a filter for his daylight, he added various colours. He would like to know whether he had made any experiments with regard to mixing gases in the tube.

The Chairman, in proposing a hearty vote of thanks to Mr. Thorne Baker, said there was one point on which he would have liked some information, and which he was sorry to see the author had not dealt with, namely, as to what coloured glasses one ought to use to protect one's eyes. In old days, people used blue glasses, but at the present time a kind of yellow glass was in vogue. One would expect that the eye would naturally be accustomed to sunlight. For sunlight smoked glasses were used to soften the strength of the rays, but for artificial light something was required by which the excessive yellow would be moderated. He would like some information from the author on that point. With regard to the practical application of such things as spectroscopes, he thought the spectroscope was being used in a more general way than scientific people realised. Quite recently an electric light company was asked to illuminate Billingsgate Fish Market. They said there was no difficulty whatever, and put in a lot of arc lights. The heads of Billingsgate Fish Market promptly interviewed the company—using, he presumed, the language of that district—and explained that the light would not do at all, because it made the fish look unfit for human consumption. Thereupon the company spent over £100 in fitting up a laboratory with a spectroscope, and other appliances, and began working until they obtained such a light that it not only made the fish look edible, but quite attractive. They were then asked to illuminate another part of Billingsgate, which they did. The Billingsgate magnates, however, then complained that the haddocks and herrings were made unsaleable by the light, so the company had to set to work again in order to get a light which would suit the haddocks and herrings, a difficulty they succeeded in overcoming, so that at the present time Billingsgate was successfully illuminated by the City of London Electric Light Company. Having succeeded in the fish market, they illuminated the game market, where the same difficulty arose, but again it was overcome. It was always a great pleasure to anybody to listen to, or to read a paper by Mr. Thorne Baker, who was one of those people who worked away quietly at their subject, and who, when they gave a paper, crowded a tremendous lot of information into it in a very unassuming kind of way.

The vote of thanks was carried by acclamation.

Mr. T. Thorne Baker, in replying to the Chairman's question regarding the colour of glasses used for spectacles, said he had no doubt, from his experiments with bacteria which had been going on in his laboratory for the past four years, that green was the favourite colour for every kind of organic and vegetable life. The conditions of growth, reproduction and everything else were normal, and he therefore thought that the green rays were

Hosted by Google

most suitable for human beings as well. A fact which bore that out was the extraordinary lack of fatigue experienced by people who were working in mercury vapour light. In reply to Mr. Trotter, and also to those who did or did not hold with Clerk-Maxwell's theory, the Clerk-Maxwell curves varied for each person. If any Clerk-Maxwell tests were made on a person who was colour-blind it would very soon be discovered in which one of his visual curves he was deficient. But he (the author) did not think the fact of different people varying in their power to appreciate the three curves, assuming those curves to be correct, should affect any theory regarding what an apparently white light produced by three or five lines in the spectrum, could or could not do. It might just as well be said that, because some men were tall and others were short, nobody should wear boots. He had to make an apology with regard to his figure of 3 per cent. loss, which appeared to have caused a good deal of criticism. Naturally the loss which was going to be obtained by screening light varied enormously with the different type of illuminants. When correcting the proof of the paper he quite at haphazard mentioned the figure of 2 or 3 per cent., but he had in mind the arc lamp. With an arc lamp, one would simply filter out rays like the ultra-violet, which, not being visual, had no visual value; but he quite recognised that where tantalum and tungsten lamps were being dealt with, the efficiency would be much less. With regard to the tantalum spectrum he had thrown on the screen, and to which Mr. Trotter referred, he had no intention of showing it as being interesting from the electric light point of view in connection with tantalum lamps or metal filament lamps, but he was thinking more especially of research work which was going on, particularly on the Continent, at the present time, in preparing cores for arc lamp carbons. While mentioning that subject, he desired to refer to the remark of Mr. Ritchie who said he did not think he (the author) had used pure carbons. Only one of the carbon spectrograms he had shown was supposed to be with pure carbons. A very careful analysis failed to find any impurity. He had copied with the greatest accuracy he possibly could the work of somebody who was very much more qualified to speak than he himself was in order to get pure carbons, and he believed they were pure. Of course it could be argued against that, anyone would get in the arc, nitrogen lines and carbon dioxide lines, which were not present in the carbon itself. He did not mean to suggest that pure carbon should be used for arc lights, but that the impurities should be pure—that was to say that quite pure carbons ought, if possible, to be taken, and cored with standardised chemical matter. With reference to the visual and spectrophotometer test, he did not suggest the photographic tests were going to do away with the visual tests he thought it most essential they should be carried out together. Finally, he was not putting forward the suggestion of combining vapour tubes to give a white light. The whole point of the paper was to screen light in as efficient a way as possible in order to get daylight. The vapour lamps o any kind would be a compromise, although it might prove from a hygienic point of view they were a perfect compromise. There was one other point in connection with the efficiency of his filter. Later on, he would endeavour, with the permission of the editor, to publish a note about the measurements. He thought it was quite possible that he became possessed of one or two dyes, which might make the subject very much easier than would appear at first sight. The yellow screens used in photographic work for filtering out the ultra-violet rays for orthochromatic photography, until a year or two ago, used to increase the exposure by something like five or seven times. Exactly the same effect could be obtained now by only increasing the exposure about one time—that was to say, doubling it—owing to the introduction of some very transparent but efficient dyes brought out by Dr. Koenig, and through the courtesy of one of the biggest dye companies in Germany he (the author) had practically all the new dyes which were likely to be of interest to him sent over for him to test; and he thought that he must have in the case mentioned obtained possession of one or two dyes that had an increased efficiency similar to the yellow dyes, which might account for an increased efficiency in a filter. As the dyes might be of considerable value, he would be pleased to publish the names of them in the *Journal* when an opportunity occurred.

THE SVASTIKA.

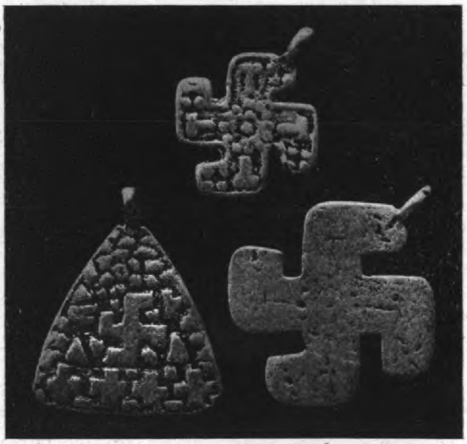
By one of the happiest of many similar happy accidents, I am able to file for record in our *Journal* the names of two more countries where the *svastika* has been in unbroken ritualistic usage from beyond the uttermost memories of their inhabitants; and to provide photographic illustrations of this profoundly interesting religious symbol as fashioned in, or for, each of these countries. I say, "or for," because all three of the *svastikas* photographed are of some identical alloy of silver, and are worked identically on both sides [thus indicating some community, if not actual centre of production, as in Russia], so that if hung with the transoms turned to the right, they show the cross of invitation and blessing, and if to the left of repulsion and implacable cursing; which latter form of the *svastika* European *pandits* have named *suvastika*, a nominal differentiation I never myself heard of in Bombay. No. 1, stamped on a triangular plate, is from Siberia, where it is worn only by the Buddhistic Mongolians, and is held in abhorrence by the Christians, and in its setting it recalls the left-handed *svastika* [*suvastika*] stamped on the pelvis of the Babylonian leaden figure of a woman, said to represent the goddess Nana [Anna, Ishtar, &c.], found by Schlieman in the ruins of Troy. Nos. 2 and 3, both

Hosted by Google

free *svastikas*, are from the Caucasus, where they are worn by all the inhabitants. The open-work one [No. 2] bears a rose-like, or a lily-like, form in its centre, and in each of its four limbs, representing the Earth, and the Sun revolving round it through the Heavens, from East to South, and on through West to North; while the more solid one bears obscure indications of the same figuring;—both of these *svastikas* recalling the Rosy-Cross of the illusive Rosicrucians; and likewise the crucified Gorgon Head of Medusa. I came upon all three *svastikas* at 41, Old Bond Street, opened there some three or four years ago, for the sale of "Russian Peasant Industries"; and conducted by good Russians, who gave me this information of the provenance and indigenous use of these *svastikas*.

The word *svastika* is Sanskrit. *Svaist*, literally "It is Well," is the name of the right-handed [*dakshina-patha*] *svastika* placed in India by the

2.



1. 3.

1. From Siberia. 2 and 3. From the Caucasus.

Hindus, at the head of all letters, bills [cf. our "Laus Deo"] and other documents, and at all beginnings, especially entrances, as a benediction; and *svastha*, "the condition of blessedness";—in Bombay the recipient of any Government salary, or pension, however exiguous, being delightfully and most soothingly designated *svasthya*, "the Blessed One"; and I always heard from my Brahman instructors that the word *svastika* meant, at full length, "the *tika*" [cf., "ticket," and ευστικτός, "well painted"] or "sign of Benediction," or "Blessedness." European *pandits*, however, say that *svastika* means simply "Be Blest." The Lower Greek equivalent of the word is "Gammadion," *i.e.*, "the (4) Greek G's (Γ),"—the "L catch L" of the ingenious argot of our English Schools of Design; the other equivalent of it, although not running "on all fours" with it, being the terrible "Triskelion," or "Three Legs" of Sicily, and the "Triquetra" [literally "three-cornered," as opposed to "quadrata"] or "Three [Legs of Man]," brought from Sicily, but without the inset Medusa Head, into the Isle of Man by the Crusaders; and known among ourselves as the fylfot, popularly corrupted to "fly-foot"; the term etymologically meaning—"Fill the bottom," *i.e.*, of the design with this three-limbed [or it might be four-limbed] symbol;—as a direction by a craftsmaster to his craftmates.

It has been made clear during the past thirty years that at one time or other the symbol of the *svastika* was in immemorial use throughout every country of the world; while now, with the three *svastikas* here photographed, it is demonstrable that its use has been maintained in uninterrupted sequence through countless generations down to the present day, not only in India and Farther India, but over all Higher Asia, and Northern Europe, and North America, and along the Rocky Mountains and the Andes, southward, into Peru; and across the Mediterranean, in Africa; and, in India at least, in all its aboriginal hierographic and hieroglyptic significances. It was first deliberately brought to general notice in this country by Major Edward Moor, Commissariat-General at Bombay, in his "Hindu Pantheon," 1810; and in both its rectangular Indian forms, right-handed and left-handed, as the sectarial *tikas* or "marks" on the forehead, respectively of the Bombay Jainas or Hindu Buddhists, and the *sakti* [*i.e.*, worshippers of the female power of the Creator] Hindus; and subsequently, altogether casually, by Owen Jones, in his great "Grammar of Ornament," 1856; and I reproduced Moor's plate in "The Industrial Arts of India," for the Science and Art Department, 1880. But it was Schlieman, by the illustration of the leaden cast of the Babylonian goddess Nana in his "Troy," 1883, who first really attracted the attention of this country, and of all Europe, and the Americas, to the symbol. Afterwards notices of its occurrence came in from all the four quarters of the globe it images; and Greg published his "On the Meaning and Origin of the Fylfot and Swastika," in 1884; and Count Goblet D'Alviella, his "epoch-making" [as Grant Allen rightly termed the volume] "Migration des Symboles," in 1891; which was immediately reproduced in English under my editing [with an Introduction, and added plates] by Messrs. Constable and Co.; and Max Müller wrote much about it, in the *Athenæum*, and elsewhere; while from the first I procured the use of it on bookbindings and in jewelry; until, at last, it has become one of the commonest articles of "lucky" trinketry sold by the cheap jewelers of London: but too often, most unfortunately fashioned in the form and coloured after the chromatism of the left-handed, or "unlucky" *svastika*—the so discriminated *suvastika*.

Of course, what chiefly concerned the learned of Christendom was the meaning and origin of this ubiquitous *svastika*. India proferred the answer to both questions with "a largess universal like the Sun" it symbolises. Edward Thomas, the

Hosted by Google

most scholarly, keen, and eminent of Oriental numismatists, had shown so early as 1880, in the *Numismatic Chronicle*, that the *chakra* ["Wheel"], or symbol of the sun, had been gradually replaced in ancient India [probably under the influence of the Buddhists] by the rectangular *svastika* [till then only a symbol of Fire, and of the Fire God Agni], its clockwise rotation being indicated by the directions of its four "feet" or transoms. But it was all in vain: for the *savants* of the West were still dominated by the unmeasured denunciation by Bentley of the license of the literary Hindus in the most presumptuous impostures, and the emphasis given to his reprobation of them by the flagrant forgeries foisted on Colonel Wilford, of the Honourable East India Company's Bengal Army, one of the most industrious and inspiring of the European pioneers of the revival of Sanskrit learning in India; and so no serious heed was given to the researches of Edward Thomas until Professor Percy Gardner made, in, or about, 1892, his ever-memorable discovery of a Greek coin of Megarean Mesembria [the City of "the Mid-day" sun] in Thrace, with the name of the town rendered on it by a *svastika* [represented *counter* clockwise!] prefixed by the syllable MES. That closed the controversy.

All the same, the Indian evidence, in its obvious authenticity and ever-rising volume, of the *svastika* being a solar symbol, was from the first overwhelming for any student who had studied the question in India, and at the feet of some Brahmanical Gamaliel. It is not only that it appears as a tangible object everywhere — on temples, and sculptures, and houses; on coins; on documents of any formality and importance; on various utensils, and on carpets, and hangings and textile fabrics of all denominations; and in jewelry of every kind; in short, universally, and always with its benedictory meaning clearly articulate; but its name is applied also to the act of the *pradakshana* [proceeding by the right hand] or circumambulation of the sacred *tulsi* plant [*Ocymum sanctum*], and of any shrine; and to the sun's procession through the Heavens, and of the movement of the shadows cast on the Earth by the buildings, trees, etc., the sun, on its southward and westward course, may shine upon:— and it is remarkable that it is this course of the Hindu *svastika*, from East to South, and on from West to North, and not the course of the Christian Cross, from North to South, and then from East to West, that the Archbishops of Canterbury follow when they proclaim the Kings and Queens of England at their coronations in Westminster Abbey, to their assembled people. The term *svastika* is also applied to the eternal *pradakshana*, or revolution of the whole stellar Cosmos about its unknown and unknowable postulated centre, to which the name of "Hercules," has been so bathetically given. Again Hindu temples are but shrines, providing no space for congregational worship; being, in my opinion, simply architectonic reproductions of the covered bullock-cart in which the Hindu gods were carried about by the Aryas, from one camping-ground to another, across the Indus and along the course of the Ganges during their earliest immigrations from Central Asia into Hindustan, and consist simply of (1) a cubical shrine [*vimana*], representting the body of the cart, and containing the idol, (2) a pinacle [*sikhara*] of a sightly curved profile, [like that of the spire of the parish church of Ambleside], terminating in a finial [*amlika*, or *aonla—i.e.*, shaped like the fruit of "*Phyllanthus Emblica*"], and representing the canopy of the cart, and (3) a porch [*mantapa*] representing the awning over the bullock-driver's seat in front of the cart. This is the type of the Hindu temple all through Maharashtra, or the Mahratta Deccan ["Right-hand-going-sun-land"], and in all these temples the pavement round-about, or, rather, square-about, the shrine, or *vimana*, is called the *svastika*. The very way, "by the right," in which our clock-handles turn, transparently refers back at last to the attribution of an ardently-breathed blessing, by the archaic Aryan worshippers of the rising sun, to everything that was reflective of, or remindful of, its right-hand course through the high Heavens; and our words, "righteousness," and "dexterity," and "sinister" all take us directly back to this sun-worship of our barbarian forefathers, as they appear emergent out of savagery; and to this day, although our "handed" clocks were not invented before the eighth century, A.D., nothing is regarded among us as more "unlucky" than to move the hands of a clock backwards, that is "by the left." Moreover, "*svastika*" is a Hindu synonym of the paired "Fishes" of the Zodiac; and not because they are often represented crossed, but because all through the past 2,000 years the Sun at the Vernal Equinox has risen in the sign of Pisces, as for 2,000 years before that he rose in Aries, and again 2,000 years before that in Taurus; and presently the Sun at the Vernal Equinox will come under the sign of Aquarius, otherwise of the "Vase of Ichor," marking in the theologised astronomy of the Hindus, which is both Babylonian and Greek, the opening "as with a noise of thunder" of "the seal" of a new "Dispensation" of all things mundane and celestial; but whether of greater felicity than those which have passed away or of greater woes—"filling the wide Vessel of the Universe" with blood—"the magicians and the astrologers, and the sorcerers, and the Chaldæans" [Cicero, Div. ii. 47] of India are too subtle-witted to "entertain conjecture," before they know!

And the *svastika* survives in India to this day as a symbol of Fire and of Agni, as well as of the Sun [Surya], lighting up for us "the dark backward and abysm" of the time when the Hindu Aryas were as yet primæval savages, and fire was for them the highest connotation of Divinity; and was artificially produced by plugging two crossed bars

Hosted by Google

of wood into [a square box [*pramatha*], the box [tinder-box!] wherein Prometheus concealed the Fire he "stole from Heaven," and violently rubbing them round and round with a stump of well-dried wood, until ignited by the calorific force, the "Promethean heat," thus generated. I have a ladle of "blackwood" [*Dalbergia* sp.] once used for pouring oil on the sacrificial fires of the last temple of Agni remaining in the Presidency of Bombay. It is about two feet two inches in length, and almost as heavy as iron; and fashioned like a sceptre. Just 1½ inches below the pear-shaped bowl [6 by 3¾ inches], carved so as to resemble the *yoni-linga* symbol, there is, in violent interruption of the artistic configuration of the ladle, a cubical block [about 3½ by 3½ by 1½ inches] having its upper surface deeply carved out with a bold representation of the rectangular, four-plugged, *svastika*, and its lower surface with a shallow and weak representation of a tortoise; the Tortoise that supports the Elephant, that bears up the world in space; and 5½ inches from the end of the ladle its handle expands into a circular mass, 2½ inches in diameter, and 1½ inch in depth, bearing on its upper surface the conventional eight-petalled representation of the Indian Sacred Water Lily [*Nelumbium speciosum*], the "Rose" of the Rosicrucians. I believe this ladle to be an absolutely unique relic of the rapidly obsolescing temple [not domestic] worship of Agni in Western India; and that the "cuboid mass" interpolated in its handle is an almost literal reproduction of the Promethean Fire-box.

Finally, for the guidance of jewelers: the right-handed *svastika*, the symbol of the sun, and of light, and the highest heavenly glories and majesties, and of man, and health and happiness, and all blessing, and blessedness, spiritual and material, temporal and eternal—alone is "lucky"; and can be fashioned only of gold, and coloured, if enameled on any other metal, only red the colour of the East, or yellow the colour of the South. The left-handed *svastika*, or *suvastika*, is the symbol of the moon, and of moonlight [Virgil, Æn. vi. 270], and all darkness, and supernatural terrors, and of woman, and all mortal diseases and disgraces, and every infernal imprecation and degree of damnation—and can be fashioned only of silver, and coloured, if enameled on any other metal, only blue or green, or yellow or white, blue or green being the colour of the West, and white or black of the North; and its proper *precious* metal, and any of its proper colours, are deadly unlucky, even if used in the fashioning of a right-handed *svastika*:—the *suvastika* being, indeed, the most potent of maledictory symbols, more ruthless and relentless in its ghastly tentacular grip than the crushing coils of the Anaconda, and more lethiferous in the malignancies emanating from it than the envenomed exhalations of the fabled Upas tree. If worn suspended, both *svastikas* should be hung from one of their corners, and not from any side of them. In the plate added by me to D'Alviella's "Migration of Symbols" is a *svastika* as rendered in Arabic of one of "the 99 names of God, from a mosque in India, where it is the equivalent of the upheld hand of God to be seen on some Saracenic buildings in Spain" [Exod. xviii. 11]. The Hindu coloration of the four quarters of the Earth and the Heavens—Red, Yellow, Blue, and White—is correctly represented on the distinguishing flag of the Peninsular and Oriental Steam Navigation Company.

GEORGE BIRDWOOD.

SNAIL-FARMING AND CONSUMPTION OF SNAILS IN FRANCE.

The demand for snails, as an article of food, in France is said to have greatly increased of late years. It is estimated that Paris alone consumes upwards of 100 millions of this mollusc annually, of which no fewer than 84 millions are sold at the Halles Centrales. The two species of edible snail sold in the market are the "Escargot de Bourgogne," the *Helix pomatia* of the naturalist, commonly known as "le gros blanc," and a smaller kind (*Helix aperta*), "le petit gris," with a shell of dark mottled-grey colour. The former, which is the most appreciated, and commands the highest prices, is found principally in the wine-growing districts of the east and south-east of France, whilst the other is common in fields and gardens in the west and other parts of the country. The vineyards of Burgundy and Champagne being no longer able to meet the present demand, the chief supplies for the Paris market are now obtained from the departments of Bouches-du-Rhône, Daubs, Somme, Sarthe, Vendée, Calvados, Seine-Inférieure, and the Côte d'Or. Snails are also imported from Italy, Switzerland, and even Germany. Lately, important consignments of snails have been sent from Algeria to the Halles.

The habits of the snail are too well known to need description here. It is hermaphrodite, and lays from fifty to sixty eggs in the early spring, and occasionally again in July. The eggs hatch twenty-five to forty days later. At the first sign of cold in the autumn, the snail hides in holes, closing at the same time the entrance to its shell with a fluid secretion, which, when dry, forms a film of a calcareous substance. In this state, termed *bouchée*, it hibernates, and remains in a torpid state until the spring.

The snails are chiefly collected by children, who hunt for them in fields, vineyards and gardens. They are sold to the dealers at the rate of a few pence per 1,000. They are placed in "escargotières," or preserves, where they are kept and fed until required for market. These preserves must be surrounded with a wall or fence to prevent the escape of the stock, for the snail is a great wanderer, and in wet weather is difficult to keep within bounds.

An escargotière should contain a number of shelters, small buildings about 6 feet by 3 feet, with a roof of tiles or boards about 18 inches from

Hosted by Google

the ground. They should be placed about 3 feet apart. The snails, about 2,000 to each shelter, are placed on a layer of dry moss. The escargotières require to be well shaded and situated on a well-drained calcareous soil.

The snail is a voracious eater of salads, cabbages, etc., in fact, nothing in the way of green food comes amiss, and it is essential that it should have an abundant supply. Being a nocturnal feeder, fresh food must be distributed round the shelters at sunset, and the débris cleared away every morning soon after sunrise. Cleanliness is the great secret of success in snail-farming, and, if this be not attended to, great mortality is sure to ensue. Crows, jays, and other birds, as well as hedgehogs and toads, are amongst the principal enemies of the snail, and must be kept away from the enclosures.

The breeding and rearing of snails for market is a far more important undertaking than that just described; it requires more care, foresight and attention. The selection of a site for such a farm is, of course, of primary importance. The soil, if not naturally of a calcareous nature, must receive a dressing of chalk, lime, or marl. It should be, if possible, well wooded, well drained, and covered with turf. The size of an enclosure will vary according to the number of snails it is intended to rear. This should not exceed 100 per square metre, or one million per hectare (about 836 per square yard), or 400,000 snails per acre.

Means for sprinkling the enclosure with water during the hot and dry weather must be provided.

Shelter in the shape of little grottoes of rockwork must be built. The ground requires to be well dug over in the early spring and covered with dry leaves, moss and even straw. The brood-snails are placed on this bedding about the middle of March. On an average, 1,000 of these will produce about 50,000, which will be hatched towards the end of April.

Snails must be abundantly fed in order to grow quickly, and if this be attended to, the "petit gris" should be ready for market by the end of the year. The larger kind, "le gros blanc," requires at least eighteen months to arrive at maturity.

The profits of a snail farm must depend largely on the cost of food, which for a large establishment is considerable. It is therefore advisable that it should be situated in the neighbourhood of market gardens, where a plentiful supply of green food can be obtained cheaply.

In the autumn, at the first sign of cold, heaps of dry leaves must be placed in the enclosure for the snails to hide in when they close their shells. They are then stored on trays in cellars or out-houses kept at a temperature of 3° C. to 6° C. (37° F. to 42° F.).

At the market, snails are denominated *courreurs* and *bouchées*. The former, as the name implies, are those in full activity, and are sold from April 15th to May 15th. They are sent to market in boxes pierced with holes, containing 500 to 2,000 each, and weighing about 25 kilogs (½ cwt.) each. As these deteriorate rapidly a quick sale is required for them. The wholesale prices of the "petit gris" vary from 1·50 francs to 2·50 francs (1*s.* 3*d.* to 2*s.* 1*d.*) per 1,000, whilst the "gros blanc" fetches from 5 francs to 12 francs (4*s.* to 10*s.*) per 1,000.

The closed snails (*bouchées*), which are sold from the middle of October until April, obtain the best prices. They keep much better. The prices for the "petit gris" range between 4 francs and 5 francs per 1,000, whilst the "gros blancs" fetch 12 francs to 25 francs per 1,000.

According to information supplied to the writer by the administration of the "Halles et Marchés" of Paris, the average price obtained for the "gros blancs" *bouchées* has been 20 francs (16*s.*) per 1,000, whilst the *courreurs* realised on the average 12 francs (9*s.* 7*d.*) per 1,000.

OBITUARY.

John Kershaw.—Mr. John Kershaw, C.E., whose death recently occurred in London, at the age of eighty-five, was a member of the Royal Society of Arts since 1882. Mr. Kershaw was articled to the late Mr. John Viret Gooch, brother of Sir Daniel Gooch, and was associated with the South-Western Railway, being afterwards (about 1860) appointed locomotive engineer of the Great Indian Peninsular Railway at Bombay. While there, he showed great skill in devising and carrying out the extensive works and mechanical arrangements of the Byculla and other depots, especially the rapidity with which he effected the haulage of the rolling-stock for the Deccan line up the famous Bhore Ghaut incline, a task for which he received the thanks of the Indian Government. After leaving India (through ill-health) Mr. Kershaw was connected with the firm of Sharp, Stewart at Manchester, and also with the railway carriage works at Oldbury, near Birmingham. His professional services included some experiments dealing with the consumption of fuel of trains, and several improvements for engine construction.

NOTES ON BOOKS.

Rating Locomotives. By H. L. Cole. London: W. Thacker & Co.; Calcutta and Simla: W. Thacker & Co. 10*s.* 6*d.* net.

The aim of this little volume is to present to railway officers as concisely as possible, and in the handy form of a pocket-book, an account of the general principles governing engine-loads and train-speeds, and the present state of knowledge regarding the actual power developed by steam locomotives and the resistance to traction of various types of rolling-stock under ordinary working conditions. The important question of brake-power also is considered. Convenient diagrammatic methods are described for dealing with various

Hosted by Google

problems connected with engine-rating and the computation of train-loads, and the free use of charts, in most cases self-explanatory, has made it possible to compress a somewhat large subject into a relatively small compass.

The author has aimed at representing only essential principles and data for everyday working. The formulæ quoted, and in some cases originated by the writer, have in all cases been tested under working conditions, in the majority of cases within the writer's own personal experience.

Written and published in India by a district locomotive superintendent of the Indian State railways, and intended primarily for the use of railway officers in India, some of the formulæ given in this book naturally refer in particular to Indian conditions. These, however, are specified; and throughout the book advantage has been taken of the most recent experiments bearing on the special subjects dealt with. In all cases the simple graphical methods suggested are such as have been found serviceable in actual practice, and their possible applications are limited by neither gauge nor country.

BUILDING CONSTRUCTION AND ARCHITECTURAL DRAWING. By John A. Reid. London: Blackie & Son, Ltd. 4*s.* net.

This work, which is designed for young students of building construction, consists of a series of eighteen large plates, illustrating brickwork, masonry, mouldings, and the various parts of a building, and a pamphlet of thirty-two pages containing some explanation of the drawings. It is intended that the illustrations should be used not for mere copying purposes, but as exercises in drawing to scale. Mr. Reid is an old pupil of the Glasgow School of Art, which has contributed so much to improve the cause of art in this country; he has also done good work as a teacher of building construction under the Glasgow School Board, and he is therefore well qualified, both by training and experience, to produce a thoroughly sound and practical work on this subject.

KAEMMERER'S PRACTICAL LETTER BOOK. Edited by Arthur Seymour Jennings. London: The Trade Papers Publishing Co., Ltd. 30*s.*

DISTINCTIVE LETTERING AND DESIGNS. By A. J. Hewett. London: The Trade Papers Publishing Co., Ltd. 1*s.*

Kaemmerer's handsome volume contains one hundred and forty large plates, illustrating several hundred alphabets. The thoroughness of the work is shown by the fact that among the illustrated alphabets are Greek, Hebrew, Anglo-Saxon, Irish, Old Gothic, Malayan and Assyrian. The book has been designed for the use of sign-painters, show-card writers, decorators, artists and craftsmen. A great many of the plates, especially the earlier ones, are, therefore, extremely plain, and hardly lend themselves to artistic treatment; but the letters are admirably clear, and serve as excellent models for the humble necessary sign-painter. It would, perhaps, have been an improvement if the names of the various styles had been printed on the plates. The book contains neither index nor list of contents, and it is therefore sometimes difficult to find what one wants, or to know, when it is found, whether it is what one wanted.

Mr. Hewett's little pamphlet contains a couple of good alphabets, which should be useful to sign-writers, etc., but a good many of his suggestions are commonplace and ugly. The short article on lettering, in which he pleads for plainness and legibility, is full of excellent common sense.

GENERAL NOTES.

THE GROWTH OF CANADIAN CITIES.—Regina, the capital of the Province of Saskatchewan, is a characteristic instance of the rapid growth of new towns throughout western Canada. Nine years ago the place had no importance, and a population of only a few hundreds. It has now developed into a busy centre, with 30,000 inhabitants. With the inflow of settlers the advantages of Regina as a strategic point for traffic was recognised by the three great transcontinental railways, who have now made it a divisional point for their respective systems. The extent of new building in 1911 amounted in value to a million sterling, and the building programme for the present year, it is stated, will exceed that amount. The municipality has also spent a quarter of a million sterling on street and other improvements. An electric street railway of seven miles has just been completed, and is municipally owned; and waterworks which will ensure a supply of water to a population of at least a hundred thousand are in hand, the machinery and piping for which are being imported from England. The wholesale houses of eastern Canada and the manufacturers of machinery are making Regina their chief distributing point for Saskatchewan, and the turnover in agricultural machinery, which reached nearly a million sterling in 1911, has never yet been equalled at any single point.

THE HOME MUSIC STUDY UNION.—This society does for music very much what is done for literature by the National Home Reading Union, to which it is affiliated. There are now about forty centres connected with it, and some nine hundred members working under its direction. For several years the executive committee has been arranging courses of study suited to various classes of musicians, and in the official organ, *The Music Student*, special articles appear dealing with these courses. The union also issues text-books on musical history and theory, and thus provides many students of music with assistance which otherwise they could not easily obtain. Conditions of membership and all further particulars may be obtained of the Secretary of the Union, 12, York Buildings, Adelphi, W.C.

Hosted by Google

International Congress of Industrial Hygiene.—An International Congress (Congrès Technique International Prévention des Accidents du Travail et d'Hygiène Industrielle) will be held at Milan from May 27th-31st, 1912, under the patronage of H.M. the King of Italy. The objects of the Congress are: (1) to make known the best means adopted in various countries to secure safety and health in workshops; and (2) to encourage the study of those practical problems of this nature which have not yet been satisfactorily solved. Further particulars may be obtained from the General Secretary, Ing. F. Massarelli, Foro Bonaparte, 61, Milan.

Coffee-growing in Madagascar. — Coffee-growing in Madagascar is beginning to take an important place amongst the agricultural industries of the island. In the Mananjary district there are no fewer than twenty coffee-growing estates, containing at least 700,000 plants, producing at the present time about 120 tons annually. It is estimated that the yield from these plantations will in a few years' time be increased to at least 500 tons. The Liberian variety of coffee is chiefly grown in Madagascar, but many planters are introducing a quality resembling East Indian, with small berries and thin husks. Madagascar coffee is beginning to find a market in France.

Electric Light for Sterilising Milk.—Attention has recently been called in Holland to the effect of ultra-violet beams on bacteria, and to the fact that such beams are abundantly developed by mercury incandescent lamps; moreover, according to the American Consul at Amsterdam, it has been stated that through this medium milk may now be sterilised in a few minutes. An apparatus has been constructed, it is explained, whereby the milk flows in a thin stream along an electric light. Demonstrations were first made with water infected with different kinds of bacteria, and it is said that the water was purified in a few minutes without appreciably increasing its temperature. The result is attributed to the quality of the ozone formed under the influence of the light, but the demonstrations must be conducted where there is sufficient room for the light to burn freely.

The Production of Nux Vomica in Ceylon.—The tree producing strychnos nux vomica grows in abundance in the jungle districts between Kurunegalla and Jaffna, of northern Ceylon. The tree is not cultivated, and the seed is gathered by natives on their own account and sold to Moorish traders, who in turn sell to the Colombo exporters. The production is not controlled. The districts in which the nux vomica seed is found are full of malaria, and for this reason the natives refrain from entering the jungle to collect the seed. It is stated that monkeys are fond of the fruit, which is to them harmless, but are careful to drop the seed, and this can be picked up with ease from the ground. However, little seed comes to the markets, and the real reason for this is most probably that in Ceylon there are so many other occupations more attractive and remunerative than the gathering of this cheap seed in the jungle. During the nine months ended March, 1911, 547 cwt. of nux vomica seed were exported from Ceylon, the value of which was about £220.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

March 13.—Professor Ernest A. Gardner, M.A., "Greek Sculpture." Lord Sanderson, G.C.B., K.C.M.G., will preside.

March 20.—F. Martin Duncan, "The Work of the Marine Biological Association." P. Chalmers Mitchell, D.Sc., LL.D., F.R.S., will preside.

March 27.—Theodore E. Salvesen, "The Whaling Industry of To-day."

April 17. — John Henry Coste, F.I.C., "Municipal Chemistry."

April 24.—George Fletcher, "Technical Education in Ireland."

May 1. — William Burton, M.A., F.C.S., "Ancient Egyptian Ceramics."

May 8.—E. D. Morel, "British Rule in Nigeria."

May 15. — Ernest Kilburn Scott, Assoc. M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere."

May 22. — Gordon Craig, "Art of the Theatre." Miss Ellen Terry will preside.

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

March 14.—E. A. Gait, I.C.S., C.I.E., Census Commissioner for India, "The Indian Census of 1911."

April 25.—Sir John O. Miller, K.C.S.I., "The Central Provinces."

May 16.—Neville Priestley, Managing Director, South Indian Railway, "Indian Railways."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

March 26.—Leonard Lovegrove, "British North Borneo."

May 7.—Alan Burgoyne, M.P., "Colonial Vine Culture."

May 21.—The Hon. J. G. Jenkins, "Australian Railways."

Hosted by Google

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

LUTHER HOOPER, "The Loom and Spindle: Past, Present, and Future." Three Lectures.

Syllabus.

LECTURE III.—MARCH 11.—*The Modern Loom for Plain and Ornamental Weaving and its Future Development.*—Eighteenth century inventions compared with those of earlier periods—The drawboy—The drawboy machine—The Jacquard machine or *draw-engine*—Kay's *fly shuttle*, its great utility and unexpected value—The first power-looms—Application of steam power to the loom—General adoption of the factory system in textile industries—Comparison of hand and power-looms as regards quality and speed of weaving—The effect of machine weaving on the workers—Defects of the power-loom—Electricity as applied to the loom—The loom of the future.

NOEL HEATON, B.Sc., F.C.S., "Materials and Methods of Decorative Painting." Three Lectures.

March 18, 25, April 1.

HOWARD LECTURES.

Monday evenings, at 8 o'clock:—

CAPTAIN H. R. SANKEY, R.E., M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

April 29, May 6, 13, 20.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 11...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Luther Hooper, "The Loom and Spindle: Past, Present and Future." (Lecture III.)

Mechanical Engineers, Storey's-gate, S.W., 8 p.m. (Graduates' Section.) Mr. R. D. McGroarty, "Water Softening and Purification."

Brewing, Institute of (London Section), Criterion Restaurant, Piccadilly, W., 8 p.m. Dr. W. E. Montgomery, "Some Aspects of the Licensing Question."

Sanitary Engineers, Institute of, at the Royal United Service Institution, Whitehall, S.W., 8 p.m. Mr. P. M. Fraser, "The Modern Home."

Surveyors, 12, Great George-street, S.W., 8 p.m. Discussion on Mr. Edwin Savill's paper, "The Single Tax Movement."

Geographical, Burlington-gardens, W., 8.30 p.m. Mr. J. M. Bell, "The Volcanoes of New Zealand."

Post Office Electrical Engineers, Institute of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 5 p.m. Mr. H. R. Kempe, "Telegraph History."

Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Mr. C. A. Daubney, "American Architecture."

TUESDAY, MARCH 12...Sociological, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.15 p.m. Mr. W. McDougall, "The Will of the People."

Asiatic, 22, Albemarle-street, W., 4 p.m. Mr. R. Grant Brown, "The Use of the Roman Character for Oriental Languages."

Roman Studies, Society for the Promotion of, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Annual Meeting.

Royal Institution, Albemarle-street, W., 3 p.m. Dr. T. R. Holmes, "Ancient Britain." (Lecture I.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on papers by Professor John Goodman, 1. "Roller and Ball Bearings," and "The Testing of Anti-Friction Bearing Metals." 2. Messrs. A. B. McDonald and G. M. Taylor, "The Main Drainage of Glasgow." 3. Mr. W. C. Easton, "The Construction of the Glasgow Main-Drainage Works." 4. Mr. D. H. Morton, "Glasgow Main Drainage: The Mechanical Equipment of the Western Works and of the Kinning Park Pumping-Station."

Engineers, Junior Institution of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Mr. B. D. Fox, "Railless Electric Traction."

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. Alfred Watkins, "New Methods of Speed and Gamma Testing."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. Sir Ernest Birch, "The Federated Malay States."

WEDNESDAY, MARCH 13..ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Professor E. A. Gardner, "Greek Sculpture."

Biblical Archæology, 37, Gt. Russell-st., W.C., 4.30 p.m.

Geological, Burlington House, W., 8 p.m.

Automobile Engineers, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. Mr. G. de Haviland, "Materials used in the Construction of Aeroplanes."

St. Paul's Ecclesiological Society, Chapter House, St. Paul's, E.C., 8 p.m. Mr. A. W. Clapham, "St. John's Priory, Clerkenwell, and its Buildings."

Japan Society, 20, Hanover-square, W., 8.30 p.m. Professor K. Ito, "The Japanese Paintings Exhibited at the British Museum."

Royal Society of Literature, 20, Hanover-square, W., 5.15 p.m. Professor A. C. Benson, "Realism in English Fiction."

THURSDAY, MARCH 14...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Mr. E. A. Gait, "The Indian Census of 1911."

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Child Study, 90, Buckingham Palace-road, S.W., 7.30 p.m. Professor W. Rippmann, "The Psychology of Spelling, with Some Proposals for its Reform."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 8 p.m. Discussion on the Interim Report of the Tests Standing Committee on the Testing of Concrete, Reinforced-Concrete and Materials employed therein."

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. Oman, "Wellington's Army, 1808–15." (Lecture III.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. W. Bickerton, "Bird Studies by Land and Sea."

FRIDAY, MARCH 15...Royal Institution, Albemarle-street, W., 9 p.m. Mr. F. Soddy, "The Origin of Radium."

Engineers, Junior Institution of, 39, Victoria-street, S.W., 8.15 p.m. Mr. A. H. Weston, "Crude Oil Engines."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting). A. E. Gladwyn, "The Heat Value of Fuels."

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Dr. Rudolf Diesel, "The Diesel Oil Engine, and its Industrial Importance, particularly for Great Britain."

SATURDAY, MARCH 16....Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Molecular Physics." (Lecture IV.)

North-East Coast Institute of Engineers and Shipbuilders, Newcastle-on-Tyne, 7.15 p.m. (Graduates' Section.) Mr. C. S. Ross, "Hydroplanes and Skimmers."

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,095. VOL. LX.

FRIDAY, MARCH 15, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 18th, 8 p.m. (Cantor Lecture.) NOEL HEATON, B.Sc., F.C.S., "Materials and Methods of Decorative Painting." (Lecture I.)

WEDNESDAY, MARCH 20th, 8 p.m. (Ordinary Meeting.) F. MARTIN DUNCAN, "The Work of the Marine Biological Association." P. CHALMERS MITCHELL, D.Sc., LL.D., F.R.S., will preside. The paper will be illustrated by lantern slides and by the cinematograph.

Further details of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday evening, March 11th, MR. LUTHER HOOPER delivered the third and final lecture of his course on "The Loom and Spindle: Past, Present, and Future."

On the motion of the Chairman a vote of thanks was accorded to Mr. Hooper for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal of the Royal Society of Arts for 1912 early in May next, and they therefore invite members of the Society to forward to the Secretary on or before Saturday, March 30th, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded as follows in previous years :—

In 1864, to Sir Rowland Hill, K.C.B., F.R.S.

In 1865, to his Imperial Majesty, Napoleon III.

In 1866, to Michael Faraday, D.C.L., F.R.S.

In 1867, to Mr. (afterwards Sir) W. Fothergill Cooke and Professor (afterwards Sir) Charles Wheatstone, F.R.S.

In 1868, to Mr. (afterwards Sir) Joseph Whitworth, LL.D., F.R.S.

In 1869, to Baron Justus von Liebig, Associate of the Institute of France, For. Memb. R.S., Chevalier of the Legion of Honour, etc.

In 1870, to Vicomte Ferdinand de Lesseps, Member of the Institute of France, Hon. G.C.S.I.

In 1871, to Mr. (afterwards Sir) Henry Cole, K.C.B.

In 1872, to Mr. (afterwards Sir) Henry Bessemer, F.R.S.

In 1873, to Michel Eugène Chevreul, For. Memb. R.S., Member of the Institute of France.

In 1874, to Mr. (afterwards Sir) C. W. Siemens, D.C.L., F.R.S.

In 1875, to Michel Chevalier.

In 1876, to Sir George B. Airy, K.C.B., F.R.S., Astronomer Royal.

In 1877, to Jean Baptiste Dumas, For. Memb. R.S., Member of the Institute of France.

In 1878, to Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S.

In 1879, to Sir William Thomson (afterwards Lord Kelvin), O.M., LL.D., D.C.L., F.R.S.

In 1880, to James Prescott Joule, LL.D., D.C.L., F.R.S.

In 1881, to August Wilhelm Hofmann, M.D., LL.D., F.R.S., Professor of Chemistry in the University of Berlin.

In 1882, to Louis Pasteur, Member of the Institute of France, For. Memb. R.S.

In 1883, to Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S.

In 1884, to Captain James Buchanan Eads.

In 1885, to Mr. (afterwards Sir) Henry Doulton.

In 1886, to Samuel Cunliffe Lister (afterwards Lord Masham).

In 1887, to HER MAJESTY QUEEN VICTORIA.

In 1888, to Professor Hermann Louis Helmholtz, For. Memb. R.S.

In 1889, to John Percy, LL.D., F.R.S.

In 1890, to Dr. (afterwards Sir) William Henry Perkin, F.R.S.

In 1891, to Sir Frederick Abel, Bart., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S.

Hosted by Google

In 1892, to Thomas Alva Edison.

In 1893, to Sir John Bennet Lawes, Bart., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S.

In 1894, to Sir Joseph (afterwards Lord) Lister, F.R.S.

In 1895, to Sir Isaac Lowthian Bell, Bart., F.R.S.

In 1896, to Professor David Edward Hughes, F.R.S.

In 1897, to George James Symons, F.R.S.

In 1898, to Professor Robert Wilhelm Bunsen, M.D., For. Memb. R.S.

In 1899, to Sir William Crookes, F.R.S.

In 1900, to Henry Wilde, F.R.S.

In 1901, to His Majesty King Edward VII.

In 1902, to Professor Alexander Graham Bell.

In 1903, to Sir Charles Augustus Hartley, K.C.M.G.

In 1904, to Walter Crane.

In 1905, to Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S.

In 1906, to Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S.

In 1907, to the Earl of Cromer, G.C.B., O.M., G.C.M.G., K.C.S.I., C.I.E.

In 1908, to Sir James Dewar, M.A., D.Sc., LL.D., F.R.S.

In 1909, to Sir Andrew Noble, K.C.B., D.Sc., D.C.L., F.R.S.

In 1910, to Madame Curie.

In 1911, to the Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S.

A full list of the services for which the medals were awarded was given in the last number of the *Journal*.

PROCEEDINGS OF THE SOCIETY.

FOURTEENTH ORDINARY MEETING.

Wednesday, March 13th, 1912; Lord Sanderson, G.C.B., K.C.M.G., Chairman of the Council of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Ba, Maung, Additional Magistrate and Small Cause Judge, Mandalay, Upper Burma.

Brunton, John Robert, 305, Padiham-road, Burnley, Lancashire.

Dass, Bahadur Luchman, c/o B. N. Rutton, Oliver Commercial School, The Mall, Lahore, India.

Finot, Leo, F.R.P.S., 27, New Bond-street, W.

Lichtenstein, Meyer, J.P., Pretoria Club, Pretoria, Transvaal, South Africa.

Okura, Kihachiro, Aoicho Akasaka-ku, Tokyo, Japan.

Sprott, Ernest M., 123, Victoria-street, S.W.

Ward-Thompson, B., Wilpshire, near Blackburn.

Young, Simon J., M.D., Main and Franklin-streets, Valparaiso, Indiana, U.S.A.

The following candidates were balloted for and duly elected members of the Society:—

Armstrong, Donald, Lieutenant (U.S. Army), Fort Williams, Maine, U.S.A.

Armstrong, Francis Tuttle, 565, West 113th-street, New York City, New York, U.S.A.

Engineer, Dhunjibhoy Temulji, Grant-road, Bombay, India.

Frere, Miss C. F., 67, Westbourne-terrace, W.

Gaye, William Charles, H.H. the Nizam's Guaranteed State Railway, Secunderabad, Deccan, India.

Mohammad, Professor Khwaja Dil, M.A., Islamia College, Lahore, India.

Napier, Robert West, 26, Bruntsfield-place, Edinburgh.

Pillow, Mrs. Margaret Eleanor, "The Grange," Thorpe-road, Norwich.

Tok, Maung Po, Tharrawaddy, Burma.

Traill, George, "Colwyn," Redington-road, West Heath, Hampstead, N.W.

Worth, Joseph Henry, Tongku, North China.

The paper read was—

GREEK SCULPTURE.

By Ernest A. Gardner, M.A.,

Yates Professor of Archæology, University College, London.

When I was invited to read a paper on Greek Sculpture before the Royal Society of Arts, I felt some difficulty in deciding what line to adopt in dealing with so vast a subject in the course of a single hour. Any theoretical or historical discussion could only be of the most summary character. On the other hand, a purely technical treatment must be assigned to a practical sculptor, unless it is to consist mainly of second-hand information. Perhaps a reasonable compromise may be found if we consider this evening the conditions under which the Greek sculptors worked, and which contributed to the extraordinary excellence they attained in their art; and, secondly, the conditions under which their work has come down to us; for these often make the understanding and appreciation of ancient sculpture very difficult to us in modern days; and the second of these two may best be considered first, for it is necessary, as a preliminary measure, to remove some prevalent misapprehensions as to Greek sculpture.

The first disadvantage under which we suffer is that we see Greek statues not in the setting for which they were originally designed, but in the halls or galleries of modern museums. Some of

Hosted by Google

these, though built expressly for their purpose, and in many ways well enough adapted to it, are uninteresting and uninspiring, a complaint sometimes brought against our own British Museum. Others, such as the Louvre at Paris, and much of the Vatican at Rome, were never designed as sculpture galleries, and leave much to be desired in the way of space and lighting, though they seem to give a romantic and picturesque setting to the sculptures and reliefs that decorate them. We may well, from a purely aesthetic and sentimental point of view, regret the days when the relics of ancient art were scattered about as the ornaments of villas and gardens—such may still be seen in some places; but it must be admitted that, while this arrangement may be admissible for works of little artistic or historical value, we are not now justified in exposing to the wasting power of the weather, and to other chances, statues that cannot be replaced and that may be the only records of a lost phase of art. I do not think the authorities of museums, or anybody else, are to be blamed for this contrast of conditions; it is inevitable, not so much from any difference of purpose or of climate, as because, to us, these statues must be guarded against any unnecessary risks of damage from weather or other causes, because we regard ourselves as responsible for their safe transmission to our successors. To the Greeks of the best period they were the products of a living art, which was still capable of producing as good or better; they cared more about their being seen and appreciated by their contemporaries than about any influence on the life and art of a generation more than 2,000 years removed. At Athens, at Olympia, at Delphi, the sacred precincts were peopled by thousands of statues in marble and in bronze, which, in the clear and luminous air of Greece, were seen as they never can be in any modern museum.

If such a setting is needed for the appreciation of individual statues, how much more is it the case with the architectural sculptures, such as those which once decorated the Parthenon, and now are arranged in the Elgin Room of the British Museum! Apart from their massive architectural frame, from their relation to one another, and to the temple as a whole, these sculptures are only partially intelligible, and lose a great deal of their effect. Yet what is now possible for us, except to arrange them in such a way as to suggest their original position and composition? It has, indeed, been suggested that the Elgin marbles, now that Athens is a place of safety, should be returned to Greece and replaced in their original surroundings. Apart from sentimental considerations, we have to face the question of what would be done with them if they were so returned at the present day. There can, I think, be no doubt that they would be placed in a museum at Athens, and that, though they might have better light and clearer air, they would be no more seen under the original conditions than they are now. They could not be replaced in their original positions in the Parthenon unless the building were entirely reconstructed; and, even if this course were taken, they would be so much exposed to damage from weather that it would probably be considered unjustifiable to leave them thus unprotected; for the force of weathering is not merely cumulative, but rapidly increases in its disintegrating effect. Although, as Plutarch testifies, the Parthenon suffered remarkably little in its first 500 years, the same cannot be said of the succeeding 1,000, or even of the time since 1800 A.D., to judge from Elgin's casts. We have to be content to see such portions of the sculpture as are still left on the Parthenon and the Theseum; and these are most valuable, for example, in exposing the fallacy that they could not be seen properly when in their places. But, even if complete restoration were attempted, casts would have to take the place of the original sculptures, which must always henceforth be protected from damage or weathering. An interesting example of the restoration of the original setting of a great series of architectural sculptures may be seen in the exhibition of the Pergamene sculptures at Berlin, where the whole of the great altar to which they belonged has been reconstructed and placed bodily within a modern building to give it shelter. Such a proceeding is not always possible. But enough has been said to show how, in every case, we must exercise our imagination to realise the conditions under which works of ancient sculpture were originally meant to be seen, and to appreciate them in relation to those conditions.

Next to this question of exhibition comes the question of restoration. Here, again, the older practice was fairly simple. So long as statues were regarded as objects of decoration rather than as records or monuments for historical or artistic study, they were usually completed if incomplete when they were found; their whole surface was worked over to give them a fresh and white appearance; missing limbs or heads or bodies were replaced either by old ones that

Hosted by Google

could be made to do, or by new ones after the restorer's phantasy. In some cases, no doubt, the restorer was influenced, consciously or unconsciously, by other statues of a similar type which he had seen, and so made some attempt at what we should now call a scientific restoration. But more often he worked at haphazard, and the older collections, such as the Vatican or the Louvre, are full of his products, which often have but the slightest claim to any connection with ancient art. I will give one example to illustrate this from the Louvre catalogue, No. 224.

"The young Bacchus, nude, his left arm resting on the thyrsus, offers with his lowered right hand a bunch of grapes to a panther seated at his feet. . . ."

(*Modern*, the head of Bacchus and most of his hair, his right fore-arm and elbow, left fore-arm and thyrsus, a portion of right thigh, both legs and feet, the panther and the plinth.)

"Charming statue in white marble."

Yes—but whose statue? Surely the Italian restorer's. It would be easy, but not instructive, to multiply such examples. I will only quote one more case—that of the Tyrannicide Aristogeiton at Naples, whose dry and muscular figure, characteristic of the transitional age, is given an almost grotesque effect by the addition of a Lysippean head of sentimental type. The change in practice really dates from early in the last century. When the Æginetan sculptures were taken to Munich, the sculptor Thorwaldsen was employed to restore them, and he did it with so careful an imitation of the style and even of the weathering of the extant portions that it is now very difficult to tell what is his work and what is ancient. Canova was asked to do the same for the Elgin marbles, and, to his lasting glory, he replied that it would be desecration for any modern hand to attempt to restore such works—an opinion which has since, happily, prevailed. It is not merely that the restorer adds something of his own which may or may not harmonise with the original. But if he restores in marble, he must necessarily cut away many projecting portions that might have given a clue to the position of missing limbs, and he must also almost inevitably destroy the original surface in an attempt to make the old and the new harmonise in appearance. If neither of these be done, and restoration be made in plaster only, whether of the original or of a cast from it, no harm is done by restoration, and it may be instructive; and under these conditions it is in no way inconsistent with modern scientific and historical study; but the originals must always be sacred from any cutting or polishing away.

Another condition that adds to the difference between works of Greek sculpture as the Greeks saw them and as we see them at the present day, is the absence of colour. It is a common opinion —I am inclined to call it rather a popular fallacy —that sculpture is the art of abstract form, and that any addition of colour to mar its perfect whiteness is a defect and a distraction. The historical origin of this delusion is easy to trace. Greek sculpture was always coloured to some extent in the best period, and so was mediaeval sculpture. But when the cult and imitation of "the antique" set in at the Renaissance, the Greek and Græco-Roman sculptures which either had remained above ground or were dug up out of the earth had lost all the colour they once had; and hence there arose the notion of colourless white marble as the proper material for sculpture. The result is not only that unrelieved glare of the surface which, especially in a bright southern light, dazzles the eye and makes it incapable of appreciating refinements of modelling, but also that absence of detail, that blankness of expression, especially in the eye-balls, which makes so much ancient and modern sculpture void of meaning and character to the modern spectator. As a matter of fact, the custom of adding no colour to marble and giving it a high polish, probably in imitation of bronze, did come in among certain later schools of ancient sculpture; but when they gave up colouring the iris and pupil of the eye, they also took to rendering these in some way in relief, whether in a purely conventional imitation of the natural forms, or by an impressionistic method such as is now favoured by modern sculptors. The actual practice of the ancients in this matter was for a long time a matter of conjecture; and there were a certain number of people who, in the absence of definite evidence, clung to the old prejudice against the application of colour to marble, and preferred to believe that the Greeks could not have done a thing that seemed to them tasteless and barbaric. But the discoveries of recent years have yielded us a good many examples of ancient sculpture still retaining its original colouring, or at least sufficient traces of it to enable us to realise what that original colouring was like. Notably, we have the series of early architectural groups in soft limestone from the Acropolis of Athens, the series of early female statues in marble from the same site, and the wonderfully preserved sarcophagus from

Hosted by Google

Sidon, especially the so-called Alexander sarcophagus. And these sculptures show us the effect of colour as applied to stone and marble, both in the early days of Greek sculpture and during its most advanced period. If we set aside the early sculptures in rough limestone, in which a complete and opaque coat of colour hid the inferior texture of the material, we find that the application of colour is both conventional in its scheme and limited in its application. The usual rule, for sculpture as for architecture, is that the broad structural masses are left plain, and that details only, such as the borders of garments, hair and lips and eye-balls, are coloured; and when colour is applied in this way, so far from obscuring the beautiful texture of the material, it enhances it by contrast. The gain in expression when the iris and pupil of the eye are thus indicated, may best be appreciated in the heads from the Alexander sarcophagus, and with their help we can realise in imagination what other Greek heads of about the same date ought to look like. In addition to this painting of details, we also find that the whole surface of the flesh parts, for example, was toned down or polished, sometimes with some addition of a colour or tint. In this case the colour is not opaque but transparent, and again makes it easier, not more difficult, to appreciate the texture of the material. I think it is a suspicion that paint is used to conceal an inferior material which is responsible for much of the prejudice against coloured sculpture.

But even after we have realised in our imagination what any work of Greek sculpture was like when it left the sculptor's workshop; when we have allowed for the conditions under which it was meant to be seen, and have eliminated in our mind not only the ravages of time, but the additions and modifications of the modern restorer, we have still to consider whether it is an original Greek work or a copy, made in all probability for the Roman market. There is an immense number of such copies in all our museums, and in many cases the masterpieces of the great sculptors of the fifth and fourth centuries—of the age of Phidias and Praxiteles—only survive for us in this form. The difference between a copy and an original work is always great; but it varies considerably according to the period when the copy was made and other conditions. It may be said, in general, that a copy of Roman date, while it is more likely to aim at mechanical accuracy, is less likely to catch the subtler qualities, the spirit and character of the original; while a Greek copy or replica, whether contemporary with or later than the work it reproduces, is likely to give us a truer notion of these subtler qualities, even though it be less faithful in details and accessories. An excellent example is offered by the head of the Meleager in the garden of the Villa Medici, as compared with the Græco-Roman version of the same in the Vatican Meleager. This is a matter in which one or two actual examples are more instructive than any amount of description. As another example we may take the Agias, a contemporary replica of a statue by Lysippus, in comparison with the Apoxyomenos, probably a Græco-Roman copy of a Lysippean work.

If, however, we would appreciate and understand the essential differences between ancient and modern sculpture, we must not only consider all these external and more or less accidental conditions and relations, but also the conditions under which the ancient Greek sculptor actually worked. Here, what might at first sight appear to be his restrictions and limitations were really his strength. He was bound by tradition and convention to a degree which is hard for us to realise. But, instead of allowing this convention to strangle his art, as was the case with the artists of Egypt and Mesopotamia, he made it serve as a channel to keep in a deep and vigorous stream the artistic impulse which else might have been diffused to no purpose. We find, in fact, that he repeats again and again, with what seems at first an almost wearisome monotony, a limited number of fixed types. But such a repetition of types is by no means always a sign of weakness in art; we have only to think of the iteration of familiar types, such as the Madonna and Child, in Mediæval and Renaissance painting. It is not, however, a merely mechanical repetition; for the early Greek sculptor was constantly observing nature and striving to embody the results of his observations in his repetitions of the well-known types. We can see this most clearly if we take one only of these types, that of the nude male standing figure, and follow out its development in some detail. In its origin this type was evidently borrowed from the common Egyptian type; but it was used by the early Greek artists, in a practically indistinguishable form, to represent a god in a temple—above all, Apollo—a victorious athlete, or a conventional portrait of the deceased set up over a tomb. But the type as we may see it, was not merely conventionally borrowed. It was repeated again and again from the trained memory of the artist, and this trained memory,

Hosted by Google

by ascertained psychological rules, retained only two aspects of the figure, the full face and the profile; but at the same time he was able to produce his figures, working freehand from memory, with an extraordinary degree of certainty and facility. He was thus able to dispense not only with a posed living model before him as he worked, but also with any full-sized model of clay or other material to guide him in his work. Small workshop models, or sketches in wax, may, of course, have been used. But it was, above all, on his memory, and on a memory reinforced by family and school tradition, that the sculptor depended. Again, he was able to dispense wth a poised living model because he constantly had before him the living body in exercise in the gymnasia and wrestling schools that were constantly frequented by all the men of the state; the custom of athletic nudity thus gave the sculptor an opportunity for study of the living and moving athletic form such as never has existed before or since; and consequently it is above all in the nude male figure that the Greek sculptor excels; but the restriction to a few clearly-defined poses enabled him to concentrate all his attention upon the improvement in proportion and in detailed modelling; freedom of pose came later. We might easily follow the same line of development in other types—the draped female figure, for example, where the beauty and sculpturesque fitness of the clothes worn in ordinary life obviated the necessity for draping a posed model in unusual garments; or the flying victory, the wounded warrior, or other less obvious types, each developed on its own special lines.

It was by such means as this that there was built up a series of types, a basis of naturalism that offered a firm foundation for the idealism of the fifth century; and though this basis was modified to some extent by later realism, it was never completely lost. Even later Greek art, though it freed itself from the trammels of early convention, never substituted for it the complete anarchy we too often find in modern work. As a result, it may sometimes lapse into the somewhat lifeless tradition of the later classical age; but at least it preserves even then much of the character of the great period of Greek art, so that it was possible for men like Lessing and Winkelmann to recognise in works like the Laocoon and the Apollo Belvedere those essential qualities of Greek sculpture for which we prefer to go to the Elgin marbles.

DISCUSSION.

THE CHAIRMAN remarked that he supposed there were two subjects upon which almost every individual thought he was able to express an opinion, however little he might have studied them; one was politics and the other was art. He further supposed every individual must have some kind of taste, although open to the risk, perhaps, of being like a certain illustrious person of whom it was said he had a great deal of taste, and it was, all of it, bad. He (the Chairman) reflected when he had been invited to take the chair on the present occasion that his recollections and knowledge of Greek sculpture were not altogether absent but somewhat hazy, and he therefore did what he always did in a difficulty, went to the British Museum. That institution happened to be closed in consequence of certain occurrences to which he need not further refer, but he was received with great civility by Mr. Arthur Smith, the Keeper of Greek and Roman Antiquities, who was kind enough to take him to see the collection of casts illustrative of Greek and Roman art. On the way he was shown a new acquisition to the Museum—a bronze head of Augustus, with the pupils of the eyes painted, and that addition was very remarkable and striking. As Mr. Smith took him over the collection of casts—photographs of many of which had been thrown on the screen that evening—what had struck him most forcibly was the great suddenness with which Greek art seemed to have blazed into what was considered perfection. Firstly, there was the "Gate of Lions" from Mycenæ, of which Edmond About remarked irreverently that it reminded him of the pictures he had drawn as a boy on his slate, adding the epigram that the childhood of art was very like the art of childhood. Then followed a series of rather stiff sculptures, all slowly struggling towards Nature and endeavouring to put on a not very attractive style. Then suddenly Myron produced a statue of a cow, about which little was known except that it was a very beautiful cow, and also a man throwing a discus, which were full of life and action. From that one came into the age of Phidias, whose incomparable work all admired. What was remarkable about that transition was that it did not take place in a time of great peace and quiet, when the people could devote themselves to peaceful art, but it happened at a time of unrest. The Greeks had been overrun by the Persians and with great difficulty had driven them out. Thereupon there was a kind of ebullition and it seemed to him as if the Greeks at the same time as they threw off the Persians also threw off the Oriental influence and developed their own art. Turning to the author's observations on the question of surroundings, he thought all must agree that upon the whole it was not a matter of which we should repent that a certain number of the best specimens of Greek art should be safely housed in our museums; but it was quite

Hosted by Google

clear the surroundings were such that the full value of the specimens could not be appreciated. For instance, when one stood in the Ephesus Room of the British Museum, it required a good deal of imagination to reconstruct in the mind's eye the original scene. On one side were the sculptured drums forming the bases of columns, and on the other side was an enormous capital of a column, and one had to erect in one's mind a series of tremendous columns with the statues all round, which was an extremely difficult thing to do. He had always thought when one of the great exhibitions was being constructed that it would be well worth while to attempt to reproduce such a thing as the Temple of Ephesus. The Temple of Ephesus could not be reproduced inside the Museum but it might be erected outside. He, however, supposed the cost would be prohibitive. When he was a boy at school he was always taught to believe that the beauty of the Phidias chryselephantine statue of Athene in the Parthenon was most magnificent, and he confessed he was thunderstruck when he went to the British Museum and saw what seemed to be a dumpy-looking statuette with its helmet covered with almost Indian-looking ornaments. He presumed that was an indifferent reproduction. Again, he thought it would be an excellent thing if in one of the great exhibitions there was a reproduction of that great statue on its pedestal forty feet high. That led him on to another point which was, perhaps, a little outside the scope of the lecture. On the question of surroundings, he did not think it was often considered how very much our own public monuments, upon which so much criticism was showered, suffered from the circumstances in which they were placed. With a murky atmosphere, with a background of grimy buildings, and with a climate which insisted upon half tints, and which made high colouring and brightness look crude, it was almost impossible that statues could really have their full effect; and he had often thought, as he had stood by some of those which were most criticised, that if they had been put somewhere else, say in Italy or in Germany, they would have been thought much more highly of. He remembered during a discussion the late Duke of Devonshire saying, "I suppose if the Albert Memorial had been put up somewhere a great many miles off in a foreign country, we should go in crowds to look at it." No doubt there were many who would dissent from that view, though to him (the speaker) the Albert Memorial seemed not far short of a very fine work. Upon the whole, considering the difficulties under which they laboured, and the fact that they had not the opportunity of seeing a number of people constantly running about with very few clothes on, and that they had such a climate to work in and to exhibit their works in, it was a matter of surprise that our sculptors turned out such fine work as they did. The author had kept those present that evening in a fairy-like country, where they had been able to think of other things than their own material interests, and he had given them a great deal which was very suggestive. No doubt, if experts had been present there might have been a lively discussion on the question of colouring and tinting of statues. He (the speaker) was not quite certain whether—at all events, in northern countries—it was possible to introduce colouring to the extent to which it could be introduced in brighter atmospheres, but there could be no doubt that the Greeks did use colouring, and that they admired it very much. He had the greatest pleasure in proposing a hearty vote of thanks to the author for his interesting paper.

Professor Gardner, in replying to the suggestions of the Chairman, said he certainly thought that everybody who had studied the history of Greek sculpture must have been immensely impressed with the fact that the progress in the art had been extraordinarily rapid during the fifth century. But art had a way of progressing in that extraordinarily rapid manner at different times. In the same way the progress of art in Florence at the time of the Renaissance was most rapid for a certain time. There seemed to be a kind of wave that came over the artistic spirit which carried artistic production far beyond its previous limits, and if one or two men of supreme genius appeared at the moment it would be found they reached an attainment which was quite incredible when compared with the work of a very short time before. There was no doubt the connection between the improvement in the art of the Greeks and their defeat of the Persians was very close indeed. It was an immense inspiration to the Greeks. Previously they had regarded the great Oriental monarchy as a thing to be looked up to, but when they found they could beat the Persians in war—which might not be the highest form of victory, but it was the only form of victory we knew—and when they found that they, as a free people, were actually able not only to hold their own, but to defeat an immensely greater army, it gave them a dignity and self-respect, and a power of idealising themselves and all that belonged to them which contributed enormously to that wonderful development which had taken place. With regard to the practical suggestions, he should very much like to see them carried out in connection with exhibitions. As the Chairman had said, it was impossible to re-erect the Temple of Ephesus in the British Museum. An attempt had been made to re-erect a portion of the Mausoleum, but that was only a very small portion, and only small pieces could be re-erected where an opportunity offered. The forms of the Temple at Ephesus were so well known that it might be possible to erect a copy of that Temple, and he would be intensely interested to see it carried out. Something had been done towards restoring the great monuments of Roman times. A very interesting experiment had been made in connection with the temple of Zeus. He thought Quatrénien De Quincy had designed a very

Hosted by Google

interesting restoration of that in gold and ivory. He did not know himself what had become of it, but it was an attempt on a fairly large scale. He sincerely wished that some such experiments could be tried in connection with the various exhibitions which were held from time to time.

THE BURMESE SILK INDUSTRY.

The natives of Burma, both men and women, wear, for the most part, costumes of silk. The costume of the men consists of a long skirt, extending from the waist to the ankles, called a "longyee," a collarless shirt or "chway-gan," over which is placed the "aain-gyee," a short coat, and a silk handkerchief is tied round the head. This costume is usually of highly-coloured silk, the favourites being pink, red, and watered silks. The coat is often of white silk covered with embroidery. The cost of these costumes varies according to the quality of silk used. The women's costumes are similar to those worn by the men, except that the skirt is much tighter, and the silk handkerchief, instead of being tied round the head, is hung around the neck, with the ends extending down the front of the body as far as the waist. The women do not wear any shoes or stockings, going either barefoot or with sandals without heels. The men of the present generation have adopted European shoes and hose, but cling to the rest of the native dress. Notwithstanding the almost universal use of silk by the Burmese, the cultivation and manufacture of silk have not been a financial success in Burma. Raw silk could be more extensively produced in Burma, according to the American Consul at Rangoon, were it not for the fact that the Burmese population, being Buddhists, dislike to undertake the cultivation of the silkworm, because the pupæ of the insects have to be killed by boiling before the reeling of silk from the cocoons. Raw silk is, therefore, mostly imported from China and Japan. Small quantities of native raw silk are, however, produced within the province. This silk, which is of dull yellow colour, is boiled in water about six hours, until it becomes white. While still moist, the silk is spun on to wooden wheels, from which, after drying, it is transferred to the dyeing vats, where it is steeped and boiled again for another hour. German aniline dyes are used. An alkaline substance called sopaya (soap) is boiled with the dye. After drying in the sun the silk is reeled again. It is then unravelled on to a hexagonal frame supported on six uprights, called a "kya," from which it is transferred to the loom and woven by hand. About five days are taken to prepare the silk from the raw state for the loom. The silk is woven into paseos (men's cloths) or loongies (women's cloths). The Chinese raw silk, called "my-pah," occurs in skeins, twelve of which form a bundle, and fifteen bundles a load, weighing from 126 to 132 pounds. Like the local silk, it is of a dirty yellow colour, which turns to white after boiling. A viss (three pounds ten ounces) is said to be reduced to three-fourths of a viss by being boiled. This raw silk is worth from twenty-five to thirty shillings per viss before boiling, but goes up to thirty-seven shillings and sixpence after boiling. It takes a man, working steadily, about five days to weave a paso nine yards long. Usually, however, he and his family work at the loom intermittently, so that a loom of silk (fifty-four yards) takes, on the average, about two months to weave. A paso of nine yards is worth from ten shillings and sixpence to seventeen shillings and sixpence. The cheapest paseos are, however, only four yards long, and sell at about eight shillings and twopence each. The width of a paso varies from fourteen to twenty-two inches. The spinning and weaving are done in the homes of the natives. Often the weaving is performed in the yard, or along the road under a thatched shed. The weavers usually work for themselves, producing the fabric as it pleases them, and sell it at the rates named. Sometimes, however, weavers are hired by Chinese or Burmese brokers at the rate of about fifteen shillings and sixpence per fifty-four yards. There are no fixed hours of working, weaving sometimes proceeding all day and part of the night, more usually for only a few hours of the day. There is no system or steady application to work. Future prospects of the silk industry in Burma are said to be poor, unless the industry be encouraged by outside demand, or restored by the introduction of new and improved methods of production and manufacture. The Burmese silk is much coarser and heavier than the Chinese and Japanese silks, which are coming into more general use by the natives on account of their finer qualities, more brilliant colouring, and cheaper price. During the calendar year 1910, raw silk, valued at about £197,000, and manufactured silk, valued at about £364,000, were imported into Burma, chiefly from China and Japan.

OSTRICH FARMING IN THE UNITED STATES.

The United States Department of Agriculture has issued a report on the ostrich industry in that country, which shows that in January, 1910, there were at least 6,100 breeding or feather-producing ostriches in the United States, of which Arizona had 80 per cent., California 17 per cent., the remainder being in Texas and Florida. The question of the nature of the country most favourable for ostriches is largely affected by the kind of vegetation peculiarly suited to the soil, which in turn is undoubtedly affected by the amount of rainfall. Alfalfa pasture makes an ideal run for the birds, furnishing a large percentage of their food; hence a soil which is, or can be, made suitable for alfalfa is one of the essentials to ostrich farming. It has been demonstrated that various parts of the United States are adapted to ostrich

Hosted by Google

breeding, and now that the results of experience have shown some of the ways in which ostrich farms may be managed successfully, there is every reason to believe that there will be a steady and marked growth in the United States ostrich industry in the near future. The demand for literature, and the number of inquiries received by the United States Agricultural Department for information concerning ostriches, indicate that the number of individuals who are interested in ostrich farming is rapidly increasing. The profit to be derived from the business will depend on the management, on the success secured in the breeding of the young birds, and on the production of feathers of good quality. The average annual yield of feathers from an ostrich is one pound and a quarter. Birds produce from twelve to twenty ounces of feathers at each plucking, with an average of sixteen ounces. The total weight of an average yield is divided roughly as follows:—"Wings," 48 per cent.; "short stuff," 25 per cent.; and "tails," 27 per cent. The amount received from the feathers of each bird varies from £4 to £6, depending upon the yield and the price of the product. The average return during the year 1909 was a little over £5 per bird. While both ostrich eggs and flesh may be used for human consumption, the amount to be derived from these products is hardly worth considering. As each pair of breeding birds is worth about £160, and chicks six months old are valued at £20, any deaths from accidents, or any inability to raise chicks greatly lessens the profit to be derived from the business. Allowing for some loss in this way, and charging a fair interest on the investment, the business can be run, it is said, to return a fair profit. The United States is reputed to be one of the greatest feather-buying markets in the world, and the amount of sales in that country has a very perceptible influence on the price. With such a market at hand, the obviously sound reasons for ostrich farming on a proper scale in the United States require no demonstration.

THE PROTECTION OF CROPS FROM HAIL.

The protection of crops from damage by hail has for some time occupied the attention of agriculturists and scientists in France. Good results have, in some cases, been obtained by the discharge of explosives during thunderstorms, but the practical working of the plan leaves much to be desired. In many cases the storm comes on too suddenly, the hail begins to fall before the gunner is at his post, and the damage is done before the firing can be commenced. The problem appears to have been solved by General de Négrier and Count de Beauchamp, by an apparatus which is at the same time simple and automatic. It is based on the fact that hailstorms are always associated with electrical disturbances. The ordinary lightning-rod, which exerts its influence over a very limited area, is quite insufficient for the protection of even a single field. A more powerful means of establishing equilibrium between the electrical conditions of the earth and atmosphere must be used.

The apparatus designed by MM. Négrier and Beauchamp, which they term "Niagara Eléctrique," appears to fulfil this condition. Its principle, which is the same as that of the lightning-rod in common use, consists mainly in a terminal or "Niagara" (so-called by the inventors), the conductor and the diffuser. The first serves, as it were, to tap the thunder cloud, and draw off the electric fluid, which passes to earth by means of the conductor. This terminal, which is made of chemically pure copper, on account of its high electric conductivity, consists of a number of points or spikes arranged round a central rod. It may be made in any suitable ornamental form, such as an aloe. This is usually made with a removable collar, to place round the cross or weather-cock of a church tower. The terminal may be placed on the summit of a church tower, factory chimney, or other high building, at a height of at least ten metres (33 feet) above the top of the highest trees in the neighbourhood. The conductor, which is made of copper plates five to eight centimetres (2 to 3¼ inches) wide, and two to two and a half centimetres (¾ to 1 inch) thick, is attached to the terminal. It should be enclosed in a lead casing to prevent oxidation, and properly protected from the weather. Care must be taken, in fixing the conductor, to avoid sharp curves and sudden turns. To the lower end of this conductor is attached the "diffuser." It is also of copper, silver-plated, and is placed in a well, running stream, pond, or underground watercourse.

The first apparatus was fixed by Count de Beauchamp, eleven years ago, on the church tower of Saint-Julien-l'Ars, in the department of Vienne, to protect his property, which, prior to this, was frequently visited by severe storms. The height of this tower is sixty metres (197 feet). The effect of this first station has been excellent, and, according to the reports of the mayor and curé of the place, no serious damage to the crops from hail, or persons or animals struck by lightning, have occurred within the protected area since it was first established.

A second station was established about three years ago, and an apparatus fixed on the tower of the church at Chauvigny, about ten kilometres (6¼ miles) off, at a height of fifty metres (164 feet), with equally satisfactory results. Chauvigny, in the valley of the Vienne, dominates an extensive arid plain formerly ravaged by hail. The third is fixed on an iron latticed post, forty metres high (131 feet), and was erected by General de Négrier at Paizay-le-Sec, in the same department. Finally, a fourth was established at Saint Sauvin, on the church tower, which is one hundred metres (328 feet) high. As the last is situated in a deep valley some sixty metres below the others, the level of the terminals of the four stations may be considered as practically the same.

Hosted by Google

A line drawn through these four stations, which are about six miles apart, forms a kind of barrier or dam (*barrage électrique*), which effectively stops the passage of the electrically-charged storm clouds, which, in this district, as is generally the case in France, come from the south-west.

This barrier, which has now been working about three years, has given excellent results, as is proved by the official reports of the local authorities, the statement after each storm being invariably "no damage" (*dégats-néant*). No hail is formed within the protected area, and hailstones, which may have been formed at some distance beyond the barrier, melt at once, without doing the slightest damage, as soon as they enter the protected zone.

It has been found, in practice, that the effect of the "Niagara" is exerted for a distance of between four and five kilometres (2½ to 3 miles) on the side of the barrier to which the storm clouds are moving, whilst on the windward side of the imaginary line between two stations its influence only extends from half to a kilometre (say three-tenths to three-fifths of a mile). In localities where storm winds may be expected from various quarters, the positions of the stations must be so arranged as to give complete shelter.

Notwithstanding that thunderstorms were very numerous and violent during the first half of last year, the crops within the protected area have not suffered. Beyond the influence of the barrier they have been severely damaged. The official reports from the mayors of Saint-Julien-l'Ars, Chauvigny, and Paizay-le-Sec, are unanimous as to the efficiency of the system, and of no damage being suffered by the crops in these districts.

A permanent committee (*Comité de défense contre les orages et la grêle*), with headquarters at Paris, has been formed, for promoting and advising on similar undertakings. A favourable report on the working of the system in the valley of the Vienne, was given in a mémoire by Professor Violle, to the Académie des Sciences, Paris; and, last year, M. de Pontbrian, senator, in a report to the agricultural department of the French Senate, strongly recommended the establishment of other "Niagaras paragrêles," to prevent damage to the vineyards and other crops by hail, in other parts of France. Other barriers are projected, and probably will be erected in various other parts of the country.

It is probable that, before long, the Eiffel Tower will be utilised as a station for this purpose, and towards the cost of this a subvention has already been granted by the Municipality of Paris. If this were done, and other stations established at the Panthéon and on the church of the Sacré Cœur at Montmartre, the whole of Paris would be effectually protected from thunderstorms.

Under ordinary conditions the cost of establishing one of these stations on a church tower, or other high building, should not exceed 2,500 francs (£100). For the protection of a large district, it is estimated that the cost would not exceed one franc per hectare (about 4½*d.* per acre).

THE JUNGFRAU RAILWAY.

The successful piercing on February 21st last of a tunnel at an altitude of 3,457 metres (11,339 feet) is an achievement which reflects great honour on Swiss engineering skill and enterprise. By the completion of this work the railway will be extended to Jungfrau Joch, where it emerges from the tunnel amidst the glaciers and perpetual snow of this lofty mountain range about 2,305 feet below the summit of the Jungfrau.

The Jungfrau railway planned by Professor Gollioz in 1895, and commenced two years later under the auspices of the Swiss railroad magnate, the late M. Guyer-Zoller, was opened for traffic as far as the Eismeer station in August, 1905. It is worked by electricity on the rack and pinion system; the gauge is one metre, and its maximum gradients are as steep as 25 per cent. (1 in 4). Starting from Scheidegg at an altitude of 2,064 metres (6,770 feet), the line ascends through pastures for a distance of about 1¼ miles, and after passing a short tunnel 92 yards in length, reaches the Eiger glacier station 7,640 feet above the sea level. The line then skirts the face of the cliff to enter a long tunnel, emerging at Rotstock (8,300 feet) at the second mile, and Eigerwand (9,406 feet above sea level) a quarter of a mile further. From hence the railway tunnel is carried on to Eismeer station (10,315 feet), a distance of 3½ miles from the starting-place at Scheidegg.

Eismeer, the present terminus of the railway, is an excellent starting-place for ascents of Mönch, Eiger, the Jungfrau, and other peaks. From this point, the line in construction to Jungfrau Joch (11,090 feet), and its extension to the terminus situated at an altitude of 13,428 feet, is mostly in tunnel for a length of about 3½ miles. The terminus will be connected with the summit, which is 4,160 metres (13,644 feet), by a lift. The total length of the railway from Scheidegg to the top of the Jungfrau is 7½ miles. About two hundred Italian miners and other workmen have been incessantly engaged for the construction of this part of the line during the last four years, in this Alpine region where the thermometer frequently registers 25° below zero C. (13° below zero F.). The temperature in the tunnel, however, never falls 3° below zero C. (26½° F.).

Eventually, it is intended to extend the line down the other side to reach the Rhône valley, and from thence to join the Simplon railway near Brieg. This would partly be worked by a cable line.

THE TONKA BEAN INDUSTRY IN VENEZUELA.

The tonka, tonqua or tonquin bean of commerce is supposed to have first reached Europe from the Province of Annam, Tonquin. It is the dried seed of the fruit of the leguminous tree called by botanists *Dipteryx odorata*, which grows in the forests of the northern part of South America. The tree attains a height of eighty feet, and the fruit

Hosted by Google

is an oblong, fibrous pod that contains one seed, almond-shaped but larger, and covered with a shiny black skin. The seeds have the sweet odour of new-mown hay. Tonka trees flourish in the Guianas, in the State of Para, Brazil, and the Orinoco basin of Venezuela. The best beans come, it is said by the International Bureau of American Republics, from a district in the vicinity of the Caura and Cuchivero Rivers, where yearly migrations of the natives convert the usually silent forests into populous localities. In the country watered by the Orinoco and its tributaries, several granite mountain ranges cross, with an average altitude, exclusive of isolated peaks, of between 3,000 and 4,000 feet. The land in the vicinity of these ranges is largely composed of detritus, in which powdered granite is present in high percentage, and this seems to be the soil best suited for the tonka-bean tree. The tree is found scattered singly throughout the forest, rarely in groves. Experience has shown that the third-year crop is generally the best, although it is almost impossible to forecast the harvest of any one year. In Venezuela the tree is known as the "Serrapia," from which the men engaged in collecting the beans earn their name "serrapieros." Early in February these men begin to arrive on the Caura from Ciudad Bolivar, or even farther distant. The old hands know every tonka-bean tree in the district, and usually confine their labours to the serrapiales with which they are familiar. Some of the more energetic of the men strike out to the untried regions, but the rapids of the upper river make such trips dangerous. When a suitable spot has been selected from which to begin operations, the men immediately build the ranches or straw houses that serve for headquarters during the two or three months following. If the fruit has commenced to fall, the men begin collecting the beans at once, otherwise they wander in the forest, marking places where the fruit is plentiful, or spend the time in hunting or fishing. Men, women, and children all take part in the collection. The fruit is much like the mango in appearance, and serves as food for the natives. It has but little pulp, which is sticky and of insipid taste, while the seed is covered with a hard fur-like substance. When the serrapiero has gathered sufficient fruit, he carries it to some open spot in the forest where he can get the benefit of strong sunlight; he here carefully breaks open the hard shell and extracts the single oblong, dark-brown bean. The seeds are then spread to dry on large granite slabs common in Venezuela. The dried beans are then shipped to Ciudad Bolivar and sold to local merchants, who may subject them to the process called crystallisation, or who may send the beans on to Trinidad, where this process can be carried on much more cheaply. Crystallising is an alcohol treatment. Open casks are ranged side by side and filled with beans to within one foot of the top. Strong rum is then poured over them until the casks are quite full, then they are covered with gunny bags. At the end of twenty-four hours the rum not absorbed is run off, and the beans are spread out to dry where the air circulates freely. When first emptied from the casks the beans are of a dull black colour, soft and swollen, but, on drying, shiny white crystals appear on their surfaces, and by the time they are ready for packing they seem to be sugar-coated. The beans shrink in drying, and present a wrinkled appearance when ready for final exportation. Tonka beans, pulverised, are mixed with snuff and tobacco to give a bouquet, and their sweet scent finds them a ready market with perfumery and soap manufacturers. Sometimes they displace the vanilla bean, but strictly speaking it is the fragrant odour that gives value to the fruit. The tonka bean is also found scattered through the forest lands of Colombia.

HORSE-BREEDING IN ANDALUSIA.

Andalusia has always been famous for its fine horses, and Jerez de la Frontera, since the seventeenth century, has been perhaps its most noted centre for horse-breeding. The town itself was one of the first and last Moorish strongholds in Spain, and the best horses there were all bred from famous Arab stallions, so that what is known as an Andalusian or Spanish horse has always a good deal of Arab blood. It has, however, been crossed with so many other breeds, especially Flemish, that to-day the Spanish horse is not registered in the books of record of pure-bred animals, according to the American Consul at Jerez de la Frontera. The Spanish Government has altogether six zones or stations for breeding horses for the army, and maintains in each a "deposito semental," containing about eighty-five stallions, besides ten or twelve remount stations. At the deposito at Hospitalet, near Barcelona, only artillery horses are bred. There is also a Government "yeguada" (from "yegua," a mare), containing seven hundred mares, at a farm called Moralatta, in the Province of Cordova, and another is being formed. The "deposito semental" at Jerez, established by the Spanish Goverment forty years ago, in an abandoned Carthusian manastery, called the Cartaja, is the best, and that at Seville the next best in the zone of Andalusia, which is said to be the best zone in Spain. Horse-breeding is still carried on in Jerez, but in a much lesser degree; the demand, however, is always greater than the supply. The cause of the decadence in horse-breeding in Jerez generally is a lack of means, the increase in the use of agricultural machinery, and the fact that every year many stallions are purchased and sent to Central and South America. Portugal, too, does not breed horses, and every year buys about two thousand in Andalusia. A Jerez dealer in horses says that, although the Spanish horse has been somewhat superseded of late years for certain work by the half-bred Spanish-English hackney, yet its supremacy as a saddle-horse, not only for fleetness but endurance and strength, has frequently been demonstrated.

Hosted by Google

On long and arduous journeys the only horses surviving the extreme hardships and lack of food have been the Spanish, the imported horses having succumbed. They undoubtedly are gifted with great endurance, and have a tenacity of life truly remarkable. It is stated that no matter what class of animal is brought to Andalusia, in two generations it acquires this remarkable toughness and endurance. This is said to be due partly to the climate, but principally to their feeding on a rich wild clover, called "zulla," found only in the Province of Cadiz, which people in that district say is the finest food in the world for horses. The zulla is very rich in sustenance, and grows to three or four feet in height, and with more luxuriance in chalky, clayey soil, such as is found in the vineyards which produce the famous Jerez wine or sherry. It is never sown or cultivated, as it seems to grow best wild. A large quantity, as much as forty tons to the hectare (2·47 acres), is sometimes gathered, and is cut and dried like hay.

RADIUM BATHS IN BOHEMIA.

The old town of St. Joachimstal, at an elevation of over two thousand feet in the ore mountains, about twenty miles north of Carlsbad, was once famous for its silver mines. As early as the year 1545 the National Government came into possession of the mines, and proceeded with the mintage of the original silver dollar, the so-called "Joachimsthaler." Long after the silver and copper mining activities of St. Joachimsthal had come to an end, other ores, such as bismuth, nickel, and, more particularly, uranium, were mined there. The last was used for colouring glass and porcelain, which are extensively manufactured in the vicinity of the old town. However, it is only since the discovery of radium that the St. Joachimstal uranium deposits have become famous. They are richer in this most precious element than any similar deposits in the world. The chief use of radium is for medicinal purposes, and, recognising this, the Austrian Government, several years ago, installed a provisional bath house near the mines. It was then demonstrated that the results of the radium treatment were most satisfactory in cases of gout, rheumatism of the joints, neuralgia, and similar diseases. The American Consul at Carlsbad states that, under the direction of the Austrian Ministry of Public Works, the building of a modern bath establishment was begun at the mines in the summer of 1910, and this was formally opened on October 22nd, 1911, in the presence of various high government officials. The building is equipped with the latest and most practical devices for the application of radium therapeutics. Although certain solutions of salts of radium are injected under the patient's skin, the principal method of application of the radium treatment is by the use of "emanations" from the element. The radio-activity, both of water and air, is utilised in these cures. The new bath establishment has numerous bath-rooms, where warmed radio-active water from the uranium mines is available in tubs, the exact degree of radio-activity necessary for every case being carefully regulated. Besides the emanation from the water through the skin, provision has been made for drinking the radio-active water, as well as inhaling radio-active air. The very latest scientific inventions are used to preserve the radio-activity of the waters. The medical director of the establishment has invented a flask, by means of which the St. Joachimstal waters can be shipped with a minimum loss of their radio-activity. Inasmuch as the building of the large and modern establishment at St. Joachimstal is expected to make the old town a "cure resort" of the first order, the next step, according to the Consul, will probably be the building of up-to-date hotels in the village. Eminent authorities have stated that the radio-activity of the St. Joachimstal waters is far greater than that of any other mineral spring, so it is not improbable that St. Joachimstal may become a notable addition to the already long list of celebrated Bohemian Spas.

CORRESPONDENCE.

THE SVASTIKA.

Having just read with great interest and admiration Sir George Birdwood's article on the svastika, it occurs to me that he deals out from his great stores of recondite learning with such a—I was going to say prodigal hand, but rather say *steam shovel—that it is really necessary to* "stand from under" in order to avoid accident. I have been hit on the head by a small lump which seems to consist of an extremely ancient name accidentally stuck to a very modern thing, where Sir George tells us the term "svastika" is applied to the revolution of the whole stellar cosmos about a centre bathetically called Hercules.

This motion is one of the most recent discoveries of astronomy, and could only be discovered since instruments could be made capable of measuring angles to one tenth of a second, say, within the lifetime of men now living. That men of this period in India, even if they had ever heard of this motion, should apply the name svastika to it seems a matter of very small importance, from which nothing of value could be inferred.

R. T. Mallet.

In reply to our member, Mr. Mallet, I regret that my article on the *svastika* did not make it plainer that it is not I, but the Hindus themselves, who have come to extend that ancient term to the modern European hypothesis of the sublime *pradakshana* of all the whole universe about a postulated "Hercules," or rather, I presume I should say, a postulated centre identified with Hercules. But this apart, the Hindus have always had a vague conception of the circulation of the

Hosted by Google

total visible universe around a common centre in its Maker and Father.

I would take this opportunity to reply also to two private correspondents in the same connection. (1) I did not include right-handed passing round of the wine bottle, and dealing of cards, as instances of *pradakshana*, because that would have led me to go on, and at great length, into the question of the casting of omens by the Gods [by the right], and the receiving of them [by the right or left] by the Roman augurs; a profoundly interesting question, of which some time or other, some one can make another article. It simply shows that every one thing in this universe is every other thing; and that all at zero, or at 212°, are one and the same thing! (2) To the lady who blames me for including women among the items symbolised by the *suvastika*, my reply is similar to that given to Mr. Mallet,—that it is not of my doing, but of "the mild Hindu" symbolisers, who, all ladies should remember, are not of "the fair sex," but of the desperately unfair sex of "mankind"!

George Birdwood.

March 14th, 1912.

OBITUARY.

The Hon. Sir William Austin Zeal, K.C.M.G.—The death occurred on the 11th inst. of Sir William Austin Zeal, President of the Legislative Council of Victoria from 1892 to 1901, and a Senator of the Commonwealth Parliament from 1901 to 1907. Born in Wiltshire in 1830, he became a railway engineer in Melbourne. Developing a talent for public life, he was elected member for Castlemaine, Victoria, in 1864, and continued to sit in the Legislative Assembly till 1881, when he entered the Legislative Council. In 1892–3 he was Postmaster-General for the State, and in 1895 he was created K.C.M.G. He was a Director of the National Bank of Australia, of Messrs. Goldsbrough, Mort & Co., of the Melbourne Gas Company, and of the Australian Mutual Provident Society; a Trustee of the Melbourne Public Library, and a Territorial Magistrate for New South Wales, Queensland and Victoria. He joined the Royal Society of Arts in 1897.

John Samuel Phené, LL.D., F.S.A.—Dr. John Samuel Phené died on the 11th inst. in his ninetieth year. He was well known in Chelsea as a wealthy and eccentric old gentleman, and the owner of the "mystery house" at the corner of Oakley Street and Upper Cheyne Row. This is a high square building decorated in a most bizarre fashion, the front being covered with a jumble of twisting columns and quaint symbolic figures. He intended it to represent the Château Savigny in Central France, where his Huguenot ancestors lived. For many years he superintended the decoration, but a quarrel with the local authorities about an overhanging bit of work annoyed him, and the house was never completed. He was a great lover of trees, and is said to have been the first to suggest the planting of avenues in London streets. He served as Master of the Clothworkers' Company in 1906–7, and he was a Vice-President of the Royal Literary Society. He was elected a life member of the Royal Society of Arts in 1906, and he was also a Fellow of the Society of Antiquaries, and of the Royal Geographical and Geological Societies.

NOTES ON BOOKS.

Examination Work in Building Construction. By Henry Adams, M.Inst.C.E., M.I.Mech.E., late Professor of Engineering at the City of London College. Published by the Author, 60, Queen Victoria Street, E.C. 2*s*. 6*d*. net.

Professor Adams has collected together in this volume the examination questions and answers written by him and published at intervals in the *Journal of the Society of Architects*. The author has had great experience as examiner to the Board of Education, the Society of Architects, the Royal Sanitary Institute, and various other public bodies. He therefore knows precisely what an examiner expects from a candidate, and his answers are models of clear and concise statement, such as, unfortunately, too seldom meet the eye of the long-suffering examiner. The book contains a large number of diagrams, which have been necessarily reduced to about half the size required in the examinations.

Heat and the Principles of Thermodynamics. By Charles H. Draper, B.A., D.Sc. London: Blackie & Son, Ltd. 5*s*. net.

This is a new and revised edition of the text-book which originally appeared eighteen years ago. During that time, of course, very considerable advance has been made in the study of the subject, and the author has brought his work up to date by describing modern means of attaining and measuring very high and very low temperatures, and generally by extending the space devoted to thermometry and electrical methods. The first part of the work is experimental; the second, which deals with the principles of thermodynamics, is necessarily somewhat mathematical in nature. The book contains some specimen examination papers of the University of London and the Board of Education.

Meteorological Instruments and Weather Forecasts. By H. T. Davidge, B.Sc., M.I.E.E. London: Percival Marshall & Co. 6*d*. net.

This little pamphlet forms No. 16 in the well-known *Model Engineer* series—a series which is as excellent as it is unassuming. Mr. Davidge

Hosted by Google

explains in simple language the principles of the various kinds of thermometer, barometer, anemometer, rain recorder, sunshine recorder and other instruments used by meteorologists, and he concludes with a chapter on weather forecasts, in which he shows the use of synoptic charts, and defines the meanings of such commonly used and commonly misunderstood terms as cyclones, anticyclones, V depressions, etc. The volume only contains some ninety small pages, but anyone who has read it—and it may be read intelligibly by a tyro—will have put himself in a fair way to understand the general principles of meteorology.

GENERAL NOTES.

Exmoor Sheep for Canada.—Professor Elliott, the Superintendent of the Canadian Pacific Railway demonstration farms in Southern Alberta, purchased during his recent visit to England a small flock of Exmoor sheep for breeding purposes from the well-known flock-masters, Messrs. Tapp & Smith, of Dulverton. Professor Elliott considers that these sheep will thrive well on the foothills of the Rocky Mountains, and the experiment will be watched with great interest. He was much struck also with the Devon cattle that he saw on Exmoor, and he may induce his company later on to acquire a picked herd. Alberta is an ideal country for mixed farming and dairying, and every effort to widen the present narrow basis of agriculture in the West, which rests too exclusively on wheat-growing, is to be commended.

Southern Persia and Economic Development.—The coastal belt of Southern Persia, which is anything from fifteen to sixty miles in breadth, is, wherever sufficiently fertile, given over to the cultivation of grain, but the rainfall is the principal factor governing the possibility of export each year. Across the mountains, however, a harvest can almost always be relied upon, and yet, though the amount produced is so far above the needs of the cultivators that a considerable amount is usually set fire to, high rates and dearth of animal transport make it impossible to get a pound of this to the coast for export. Besides grain, there are, says Mr. Vice-Consul Chick, in his report just issued (No. 4823, Annual Series), certain berries and wild nuts which would be of interest for vegetable oils, and other products, such as vegetable silk, awaiting the advent of European "discovery," for Persian traders are both unaware of possible commercial uses to which produce may be put, and, further, are never willing to try experiments. Unfortunately, little pioneer work or specialisation has been done so far by European firms settled in the country. The only exception is gum tragacanth, the purchase and sorting of which has become systematised to a certain extent in Shiraz. Almonds, raisins and sultanas, linseed, sesame, and Persian tombaku should all, in Mr. Chick's opinion, repay firms undertaking purchases on a large scale from the districts where each is cultivated. But all development of the internal trade, and of improved communication, is largely dependent on port improvements. None of the present outlets of trade along the Persian shore of the Gulf are satisfactory in their present condition.

Australian Precious Stones.—A great many precious stones are found in Australia. The gem most sought after is the Australian black opal, which is found nowhere else in the world. It appears in limited quantities in the matrix of ironstone and sandstone in the Lightning Ridge district of New South Wales. It is estimated that since 1890 opals valued at over £1,200,000 have been found in the State of New South Wales. Queensland also produces many opals, the production up to the present time amounting to about £200,000. Sapphires rank next among Australian gems in value of production. They are found in New South Wales and in Queensland, chiefly in the latter State in the gravel or creek beds. The gems show excellent fire and lustre, but the colour is a darker blue than the Oriental sapphire. In Queensland the present production amounts to about £15,000 annually, the total output to date being about £150,000. Other precious stones found in different parts of Australia include emeralds, turquoises, topaz, zircons, garnets, rubies, amethysts, tourmalines and beryls. Diamonds are found to a limited extent in New South Wales and in South Australia. Pearls are found along the northern coast of Australia. The quest for pearl shells is perhaps the most important industry of the northern part of Australia.

A New Siberian Exhibition.—Several exhibitions have been held in Siberia, the last in 1899 at Khabarofsk, on the Amur River. In order to call attention to the country's progress, and show the development of the Russian Far East since then, the local authorities have decided to hold another in 1913, which will also celebrate the three hundredth anniversary of the Romanoff reign in Russia. It will be held during August and September, as the Priamur Region Exhibition of 1913, at Khabarofsk, the capital of the Priamur district. Special buildings will be erected, and permits for space for exhibits will be granted on application. Gold, silver and bronze medals, as well as diplomas and money prizes, will be granted to exhibitors. Special attention will be given to agricultural implements and machinery for preparing the land, its fertilisation, planting, harvesting, thrashing and cleaning the grain, also to machinery for preparing food for cattle, and manufacturing agricultural products. In short, all phases of agriculture, gardening, apiculture, cattle and horse-breeding, etc., will receive consideration.

The Cultivation of the Poplar Tree in Italy.—During the last few years an active propaganda has been made by some of the

Hosted by Google

principal paper-makers in Italy, to encourage the growing of the poplar in that country. This tree is very common in Piedmont and Lombardy, where it is planted on the banks of the numerous irrigation canals and the valleys of torrents and rivers. The wood is used for a variety of purposes, and especially for making packing-cases. The pulp of this wood is excellent for the manufacture of paper, being white, soft, and free from resinous substances. It is considered that by the afforestation of waste and unproductive lands, a good return for the capital expended might be obtained by the manufacture of pulp from poplar wood trees. A systematic cultivation of this tree, on the best lines of forestry practice, is strongly urged by many of the principal local agricultural societies. In consequence of the high price of wood-pulp in Italy, and in order to render themselves independent to some extent of foreign supply, a few of the leading firms have set an example by establishing their own plantations. The results of their experiments have been most satisfactory. In one case a return of 15 per cent. on the outlay is said to have been obtained. A leading firm of paper-makers, with works near Milan, a few years ago established important plantations of poplars in the valley of the Ticino, where, being subject to floods, and with a stony and gravelly soil, the land is of little value for agricultural purposes. Several thousand trees are planted here every year, and in the course of a few years these plantations, it is expected, will furnish an abundant supply of raw material for paper-making.

Apiculture in South Russia.—According to a report by the apiary committee of the Imperial Agricultural Society of Southern Russia, it appears that apiculture is a favourite occupation of small landowners and the working classes. These are assisted by the Government zemstvo organisations and some of the apiary societies having special funds for the purpose. Many of the zemstvo organisations in the south of Russia maintain warehouses of apicultural accessories, from which peasants beginning bee-keeping receive proper hives free of charge, one or two hives being given per head. In other cases they are sold at low prices on the instalment plan. The ordinary peasant can also obtain, for almost nothing, all literature at hand upon the subject of bee-culture, the poorest being supplied free of charge. Meeting the demand for them, the Government and zemstvo organisations have established schools of apiculture at Warsaw, St. Petersburg, Moscow, and elsewhere, and have introduced courses of apiculture in some of the agricultural schools for scholars and teachers in the public schools. The methods of teaching are well arranged as regards both the practical and the theoretical sides. The Government and zemstvo organisations maintain staffs of apicultural instructors, who are sent to various points to give instruction to those interested in the work, and to assist teachers already engaged in the few existing schools.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock :—

March 20.—F. Martin Duncan, "The Work of the Marine Biological Association." P. Chalmers Mitchell, D.Sc., LL.D., F.R.S., will preside.*

March 27.—Theodore E. Salvesen, "The Whaling Industry of To-day." Lord Sanderson, G.C.B., K.C.M.G., will preside.*

April 17. — John Henry Coste, F.I.C., "Municipal Chemistry." Dr. Rudolph Messel, F.R.S., will preside.

April 24.—George Fletcher, "Technical Education in Ireland."

May 1. — William Burton, M.A., F.C.S., "Ancient Egyptian Ceramics."

May 8.—E. D. Morel, "British Rule in Nigeria."

May 15. — Ernest Kilburn Scott, Assoc. M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere."

May 22. — Gordon Craig, "Art of the Theatre." Miss Ellen Terry will preside.

Indian Section.

Thursday afternoons, at 4.30 o'clock :—

April 25.—Sir John O. Miller, K.C.S.I., "The Central Provinces."

May 16.—Neville Priestley, Managing Director, South Indian Railway, "Indian Railways."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock :—

March 26.—Leonard Lovegrove, "British North Borneo." *

May 7.—Alan Burgoyne, M.P., "Colonial Vine Culture."

May 21.—The Hon. J. G. Jenkins, "Australian Railways."

Cantor Lectures.

Monday evenings, at 8 o'clock :—

Noel Heaton, B.Sc., F.C.S., "Materials and Methods of Decorative Painting." Three Lectures.

Syllabus.

Lecture I.—March 18.—*The Development of Decorative Painting.*—Definition—Necessity for knowledge of materials—Origin of different methods—Development of distemper—Fresco—Encaustic—Tempera—The methods of the mediæval painters—Rise of oil painting—Growth of pictorial art and decline of decorative treatment—The loss of tradition as regards methods of working—Problems to be faced in modern work—Choice of a method.

* These papers will be illustrated by lantern views and by the cinematograph.

Hosted by Google

LECTURE II.—MARCH 25.—*Fresco and its Modifications.*—The nature of plaster—Chemistry of fresco process—Practical details—Quality of the result—Limitations—Nature and selection of pigments—Problem of durability—Protection of surface—Modifications of the process—Fresco-secco — Stereochrome — Keim's process — Oxychloride process—Possibilities of development.

LECTURE III.—APRIL 1.—*Oil and Tempera Painting.* — Tempera: technical principles on which it depends—Nature and use of natural and artificial emulsions—Yolk of egg—Casein, etc.—Protection of the surface—The problem of varnishing. Oil painting: the technical principles on which it depends—Its scope and facilities—The question of durability—Limitations as regards ground—Modifications of oil painting—Use of wax—Spirit fresco—Resins and varnishes—Oil tempera.

HOWARD LECTURES.

Monday evenings, at 8 o'clock:—

CAPTAIN H. R. SANKEY, R.E., M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

April 29, May 6, 13, 20.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 18...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Noel Heaton, "Materials and Methods of Decorative Painting." (Lecture I.)

Bibliographical, 20, Hanover-square, W., 5 p.m. Mr. R. B. McKerrow, "English Printers' and Publishers' Devices, 1557-1640."

Surveyors, 12, Great George-street, S.W., 7 p.m. (Junior Meeting.) Mr. A. J. Baker, "Styles of Architecture in Country Houses as they affect Market Values."

British Architects, 9, Conduit-street, W., 8 p.m. Mr. W. H. Ward, "The Architecture of the French Renaissance."

Victoria Institute, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Lieutenant-Colonel Mackinlay, "Some Lucan Problems."

TUESDAY, MARCH 19...Statistical, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Mr. Percy Ashley, "The Financial Systems of Germany."

Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Papers by Mr. F. W. Goodenough and Mr. Justus Eck, "The Lighting of Printing Works and Offices."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. T. R. Holmes, "Ancient Britain." (Lecture II.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Papers by 1. Messrs. A. B. McDonald and G. M. Taylor, "The Main Drainage of Glasgow." 2. W. C. Easton, "The Construction of the Glasgow Main-Drainage Works." 3. D. H. Morton, "Glasgow Main Drainage: The Mechanical Equipment of the Western Works and of the Kinning Park Pumping-Station."

Photographic, 35, Russell-square, W.C., 8 p.m. Dr. Somerville Hastings, "Toadstools."

Zoological, Regent's Park, N.W., 8.30 p.m. 1. Mr. A. R. Dugmore, "Lantern Exhibition of Studies of Wild Animals in Africa and North America." 2. Mr. E. W. Shann, "Observations on some Alcyonaria from Singapore, with a brief discussion on the Classification of the Family Nephthyidæ." 3. Mr. G. H. Kenrick, "A List of Moths of the Family Pyralidæ collected by Felix B. Pratt and Charles B. Pratt in Dutch New Guinea in 1909-10, with Descriptions of new Species." 4. Mr. T. H. Withers, "Some early Fossil Cirripedes of the Genus *Scalpellum.*"

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. Dr. F. B. Vrooman, "British Columbia and her Imperial Outlook."

WEDNESDAY, MARCH 20..ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. F. Martin Duncan, "The Work of the Marine Biological Association."

Meteorological, 25, Great George-street, S.W., 7.30 p.m. Professor Otto Pettersson, "The Connection between Hydrographical and Meteorological Phenomena."

Microscopical, 20, Hanover-square, W., 8 p.m. Mr. F. Enock, "Fairy Flies and their Hosts."

United Service Institution, Whitehall, S.W., 3 p.m. Colonel the Right Hon. Viscount Esher, "The Coordination of the Naval and Military Services."

THURSDAY, MARCH 21...Economics and Political Science, London School of, Clare-market, W.C., 3 p.m. Dr. J. H. Lewinski, "The Origin of Property and the Development of the Village Community." (Lecture I.)

Authors, Society of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m.

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Linnean, Burlington House, W., 8 p.m. 1. Dr. I. Bolivar and Mr. C. Ferrière, "The Orthoptera-Phasmidæ of the Seychelles." 2. Professor A. Dendy, "Living Specimens of Phasmidæ." 3. Miss May Rathbone, "Phyllody of Carpels in *Trifolium repens.*" 4. Mr. J. A. Liddell, "On *Nitocrameira bdellurœ*, a New Genus of Parasitic Canthocamptidæ." 5. Mr. W. West and Professor G. S West, "On the Periodicity of the Phytoplankton of some British Lakes." 6. Mr. H. N. Dixon, "Plants from South Portugal."

Chemical, Burlington House, W., 8.30 p.m. Messrs. A. K. Macbeth and A. W. Stewart, "Iso-Erucic Acid."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. F. A. Dixey, "Seasonal Dimorphism in Butterflies." (Lecture I.)

Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Discussion on "The Causes Preventing the More General Use of Electricity for Domestic Purposes," to be opened by Mr. S. Z. de Ferranti, President.

Mining and Metallurgy, at the Geological Society, Burlington House, W., 8 p.m. Annual General Meeting.

FRIDAY, MARCH 22...Royal Institution, Albemarle-street, W., 9 p.m. Professor D'Arcy W. Thompson, "The North Sea and its Fisheries."

North-East Coast Institute of Engineers and Shipbuilders, Newcastle-on-Tyne, 7.30 p.m. Annual General Meeting.

Physical, Imperial College of Science, South Kensington, S.W., 5 p.m.

SATURDAY, MARCH 23....Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Molecular Physics." (Lecture V.)

Corrections.—Dr. F. W. Edridge-Green desires that the following corrections be made in the report of his remarks in the discussion on the paper on "Some Modern Problems of Illumination," published in the *Journal* of the 8th inst.:—On p. 459, col. 1, l. 41, for the word "methods" read "processes," and on p. 459, col. 2, l. 18, for the words "the whole of the series," read "the older theories."

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,096. VOL. LX.

FRIDAY, MARCH 22, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MARCH 25th, 8 p.m. (Cantor Lecture.) NOEL HEATON, B.Sc., F.C.S., "Materials and Methods of Decorative Painting." (Lecture II.)

TUESDAY, MARCH 26th, 4.30 p.m. (Colonial Section.) LEONARD LOVEGROVE, "British North Borneo." EARL BRASSEY, G.C.B., will preside. The paper will be illustrated by lantern-slides and by the cinematograph.

WEDNESDAY, MARCH 27th, 8 p.m. (Ordinary Meeting.) THEODORE E. SALVESEN, "The Whaling Industry of To-day." LORD SANDERSON, G.C.B., K.C.M.G., will preside. The paper will be illustrated by lantern-slides and by the cinematograph.

Further details of the Society's meetings will be found at the end of this number.

INDIAN SECTION.

Thursday afternoon, March 14th; SIR THEODORE MORISON, K.C.I.E., in the chair. A paper by MR. E. A. GAIT, I.C.S., C.I.E., Census Commissioner for India, on "The Indian Census of 1911," was read by MR. J. D. ANDERSON, M.A., I.C.S. (retired).

The paper and discussion will be published in the next number of the *Journal.*

CANTOR LECTURE.

On Monday evening, March 18th, MR. NOEL HEATON, B.Sc., F.C.S., delivered the first lecture of his course on "Materials and Methods of Decorative Painting."

The lectures will be published in the *Journal* during the summer recess.

EXAMINATIONS.

The number of entries for the Society's Commercial Examinations, which commence on March 25th, is 36,381. This number is 743 less than last year, when there were 37,124 entries.

PROCEEDINGS OF THE SOCIETY.

FIFTEENTH ORDINARY MEETING.

Wednesday, March 20th, 1912; P. CHALMERS MITCHELL, M.A., D.Sc., LL.D., F.R.S., Secretary of the Zoological Society of London, in the chair.

The following candidates were proposed for election as members of the Society:—

Beecroft, D., The Class Journal Co., 231-241, West 39th-street, New York City, U.S.A.

During, Claudius Dyonisius Hotobah, 15, Pulteney-street, Freetown, Sierra Leone, West Africa.

Hartley, Frank Reginald, 3, Esplanade-road, Scarborough, Yorks.

Jenner, Harry, 35, Auckland-road, Ilford, Essex.

Markel, Karl Emil, Ph.D., 20, Queen's Gate-terrace, S.W.

Renton, James Hall, J.P., Rowfold Grange, Billingshurst, Sussex.

Stockdale, William, Rosebank House, Stubbins, near Manchester.

Sutherland, William George, The Birches, Ashton-on-Mersey.

The following candidates were balloted for and duly elected members of the Society:—

Ainsworth, Herbert, P.O. Box 1553, Johannesburg, South Africa.

Andrews, Fred Henry, 3, Park-hill, Clapham, S.W.

Bishop, Albert E., 1, Metal Exchange Buildings, Whittington-avenue, E.C.

Dodge, Walter Phelps, The Reform Club, Pall Mall, S.W.

Hosted by Google

Kothari, Jehengir H., K.I.H., Karachi, India.

Millard, V. C. H., M.A., Shrewsbury House, Ditton-hill, Surrey.

Welch, George Winston, Danville, Kentucky, U.S.A.

The Chairman introduced the lecturer for the evening, and in doing so commended to the meeting the subject which had been set down for discussion, namely, the work of the Marine Biological Association. That association dealt entirely with the life of the sea. He need scarcely remind the meeting that all the green vegetation of the earth, all the population of the land, of fresh waters, and of the air, had taken its origin from the sea. Even we ourselves, who stood at the head of terrestrial animals, bear written deeply on the character of our structure the marks of our aquatic origin; and we all, in the pre-natal stages of our life, passed through a phase which had no meaning or sense of any kind unless one looked at it as a legacy from our ancestors who lived in the sea. The mystery of the origin of life would have to be dredged up out of the sea, if it was going to be discovered anywhere. The study of the life of the sea, therefore, he regarded as one of the most interesting subjects which could possibly engage attention. And he thought the inhabitants of this country, an island country ringed round by the salt sea, had upon them a special duty to investigate everything which happened in the sea. It was not only a duty, but it ought to be a process very profitable to us, because, although the poet wrote of "the unvintagable sea," yet there was no doubt that the harvest of the sea was one of the most profitable of all our industries. It was about those matters that Mr. Martin Duncan would speak. It was scarcely necessary to remind the audience that Mr. Duncan was the son of a very distinguished naturalist, and that he was himself a very distinguished naturalist. Mr. Martin Duncan had devoted a great deal of time to the subject, and had been one of the pioneers in applying the art of photography to the study of natural history. He had had special opportunities of observing the work of the Marine Biological Association at Plymouth, and he would lay before the meeting some of the results of the investigations he had made.

The paper read was—

THE MARINE BIOLOGICAL ASSOCIATION, AND SOME ACCOUNT OF THE WORK IT HAS ACCOMPLISHED.

By F. Martin Duncan, F.R.M.S., F.R.P.S.

It would be impossible for me to describe within the time at my command to-night all the useful and important work which has been accomplished by the Marine Biological Association since its foundation. Therefore I propose briefly to outline the character of the association, to give some idea of the results obtained during the period that the association was engaged on the work of the International Fisheries Investigations, and some account of the scientific work that has been accomplished at Plymouth; and finally, by means of the lantern and cinematograph, to show you some of my own efforts in the application of photography to marine biological investigation.

The Marine Biological Association of the United Kingdom owes its existence to a combination of scientific men interested in the advancement of marine biology, and of others who are interested in the important sea fisheries, and the many problems connected therewith—a happy combination of Science and Industry for the advancement of our knowledge on these very important subjects. The aim of the association is to afford every opportunity, both for the biological investigation of marine plants and animals, and for investigations into the habits and conditions of the life of those marine fishes which form the "harvest of the sea," and of which our present knowledge is both incomplete and insufficient.

The association was founded and constituted at an influential meeting held on March 31st, 1884, at the Royal Society. Professor Huxley was its first president, and Sir E. Ray Lankester, who initiated the movement, acted as honorary secretary. Sir E. Ray Lankester is now our president, and has through all the years which have passed since that historic meeting in the rooms of the Royal Society, taken the keenest interest in the advancement and welfare of the association. The affairs of the association are conducted by a representative council, without any charge upon its funds, so that the whole of the subscriptions and donations received are devoted absolutely to the support of the laboratory, to the prosecution of researches by the aid of its appliances, and to the advancement of the association. The income of the association is derived partly from an annual grant from His Majesty's Government, partly from an annual grant made by the Worshipful Fishmongers' Company, and by the annual subscriptions of members, special donations, the rental of tables in the laboratory, and the sale of specimens.

The laboratory at Plymouth is a handsome stone building, standing on Citadel Hill, facing the historic Sound, and close to the famous Hoe. It was opened on June 30th, 1888, the building and fittings having cost some £12,000. Since that time, investigations, practical and scientific,

Hosted by Google

have been constantly pursued. The permanent scientific staff of the association consists of a director of the laboratory, a naturalist in charge of fishery investigations, and an assistant to the director, principally occupied in the collection, identification and preservation of marine animals. The employment of additional naturalists to carry out fishery or biological investigations must necessarily depend upon the subscription of funds for that purpose by private individuals or public bodies.

In addition to the permanent scientific staff, scientific men from England and from abroad come to the laboratory at Plymouth to carry out their own independent researches, paying a small rent for the use of a working table and other appliances, and by their investigations have made valuable additions to zoological and botanical science.

The declared object of the founders of the Marine Biological Association was "to promote researches leading to the improvement of zoological and botanical science, and to an increase of our knowledge as regards the food, life-conditions, and habits of British food-fishes and molluscs"; and this double purpose of scientific investigation and of special fishery study has been strictly adhered to by the council in its management of the funds at its disposal.

The part performed by the association in the progress of biological science generally in this country is at least as important as its fishery branch, and it must be remembered that many of the purely scientific investigations carried out in the laboratory have very important indirect bearings upon the solution of practical fishery problems. Thus, repeated experiments upon the life-histories of invertebrate animals in captivity are gradually but surely revealing the proper conditions for the successful hatching and rearing of marine fishes. Practical investigations upon matters directly connected with sea-fishing are constantly in progress, and embrace a variety of subjects, including the reproduction and development of fishes, the determination of the character of the egg, larva, and young at all stages of growth, with experiments on the rearing of fishes in captivity, and on their rate of growth in confinement and in the sea. Observations have also been carried out on the relation between the distribution, seasonal migrations, and varying abundance of fishes, and the physical conditions of the sea; also upon the distribution of flat-fishes at different stages of their growth, upon their migrations, and the destruction of immature fish on particular grounds, or by particular method, of fishing.

Although the headquarters of the association are situated at Plymouth, the work carried out by its officers is national, and by no means local in character. Thus, elaborate investigations were made from 1892 to 1895 by the officers of the association, working from Grimsby and Lowestoft as centres, in regard to the destruction of immature fish in the North Sea; while in the summer of 1902 the association undertook the investigation for His Majesty's Government of the fishing-grounds in the southern part of the North Sea, and the study of the changes in the hydrographical conditions and plankton in the waters of the English Channel, and continued these important investigations until March, 1910, when the work was taken over by the Board of Agriculture and Fisheries. This work was part of a scheme of international fishery investigations which had been formulated and adopted by a conference consisting of representatives of the European Powers bordering the North Sea, and the international programme drawn up by them, in its entirety, covers a wide and important field of investigation, including a thorough physical and biological examination of the waters of the North Sea, the Northern Ocean, the English Channel, and the Baltic, together with a systematic examination of the principal fishing grounds, and a scientific study of all the biological problems bearing on sea-fisheries. The results obtained by the Marine Biological Association in the part it has taken in this work are of wide and far-reaching importance, and already a large proportion of the results obtained have been tabulated and issued in Reports presented to both Houses of Parliament.

Six years ago, on February 21st, 1906, Professor W. Garstang read a brilliant and most interesting paper before this Society upon some of the results that had been obtained by the association in connection with the International Fisheries Investigations (see Vol. LIV. page 401, *Journal of the Society of Arts*), and gave a general survey of the work in progress. It is, therefore, unnecessary for me to enter fully into the details of these important investigations carried out by, or under, the able supervision of Professor Garstang. The following brief reference to some of the methods employed and results obtained, may, I trust, be of sufficient interest to those who are not already familiar with the work, to induce them to read Professor Garstang's paper. I would draw attention first

to the experiments in the marking and liberation of flat-fish, especially plaice, which were carried out with the view of throwing some light on the migrations and rate of growth of these fish, as well as upon the intensity of fishing carried on in different areas. To most landsmen I suppose the idea of marking a fish and throwing it back again into the sea, with the prospect of its subsequent recapture, must appear a curious, if not a somewhat hopeless kind of experiment; the chances of the recapture of a marked fish from among the teeming creatures of the deep appearing superficially somewhat remote. However, the results clearly show that this is by no means the case. In all the marking experiments carried out under Professor Garstang's supervision, the labels used were based upon Dr. Petersen's model, with certain modifications, and consisted of a couple of small discs perforated in the centre, and connected by a small piece of silver wire passed through the holes. In the actual work of marking, the silver wire, with a small bone button at its lower extremity, is passed through the dorsal edge of the body of the fish on the lower or blind side, about halfway down, very carefully, so as not to cause injury, and is then connected on the upper or eyed side of the fish with an oval concave disc of thin brass. The disc bears on its concave side a letter—" E." for England—and a distinctive number stamped upon it. The convex side of the disc lies next the fish, the shape having been designed to prevent the edge of the disc from cutting into the flesh, or otherwise injuring the fish. This object has been fully attained, while the number on the disc remains perfectly legible, and the brass itself free from foreign growths, even after prolonged immersion in the sea. Only perfectly healthy, vigorous fish were marked, and these, as they were marked and measured, were returned to the deck tanks supplied with running water, and kept there until the entire series to be liberated had been dealt with, so as to provide a further opportunity of rejecting fish of impaired vitality.

To obtain tidings of the recapture of these marked fish it was absolutely necessary to gain the interest and co-operation of the fishermen, and with this end in view notices were posted up in the chief trawling ports, and other means taken to make owners, masters, and men acquainted with the nature of the work. In the notices posted up, English fishermen who caught marked fish were requested to take note of the place, depth, and date of capture, and to hand the fish, together with such particulars, to the local agent of the association, or to forward them direct to the laboratory. In return the fishermen received the following rewards:—For fish and label complete with information as to place and date of capture, 2*s.*; for label alone, with the same information, 1*s.*; for label without information, 6*d.* In the case of valuable fishes, the market price was paid in addition to the reward, and in every case the cost of postage or transit to the laboratory. This course not only enlisted the hearty co-operation of the fishermen, but aroused the sincere interest of these brave, hardworking men, so that again and again they have shown more desire to know when and where and at what size the particular fish recaptured by them were set free, than to receive their due reward.

That the chances are nowadays strongly in favour of the possibility of the recapture of marked fish may be realised when we learn that out of 1,463 plaice marked and liberated, 287, or 19 per cent., were recaptured within a year. That the larger-sized plaice are capable of making very extensive migrations in a comparatively short time the two following examples will serve as illustrations. In the first case, a marked plaice, 33 centimetres (13 inches) long, liberated on December 12th, 1903, on the Leman Ground, in the latitude of Lincolnshire, was recovered by a Hastings trawler off Winchelsea, in the English Channel, on March 23rd, 1904; the fish having travelled a minimum distance of 175 miles in a little over three months. The second fish, marked and liberated on August 12th, 1903, off the Lincolnshire coast, near Mabelthorpe, was recaptured in April, 1904, in St. Andrews Bay, having in eight months travelled a distance of 210 sea miles from the point of its liberation. The intensity of the commercial trawling in the North Sea was demonstrated in these marking experiments by the fact that out of 855 marked plaice above eight inches in length liberated outside territorial limits, the number recaptured within twelve months yielded a total of 21 per cent.; while experiments on the Dogger Bank in the spring of 1904 resulted in the recapture of more than 40 per cent. of plaice exceeding ten inches in length. How the evil results of over-trawling on the Dogger Bank might be successfully overcome by the transplanting of immature fish from the crowded inshore nurseries to the Dogger Bank, Professor Garstang fully described in his paper already mentioned.

There is one very important piece of work in connection with these International Fisheries

Hosted by Google

Investigations, carried out for the Marine Biological Association by Dr. W. Wallace, to which I should like to draw special attention, and that is, Dr. Wallace's investigations on the age and growth-rate of plaice, as determined by the appearance of the otoliths, or ear-stones, of these fish. Within the ear of a fish are to be found the usual otolithic accumulations, either in the form of fine, mucus-connected, calcareous particles, as in the elasmobranchs (sharks and rays), or as massive solid concretions in the teleosts. In the cod and haddock, for instance, one of the otoliths is strikingly large.

The otoliths, or ear-stones, of the plaice show alternate white and dark rings; the white rings being formed in spring and early summer, the dark in late summer and autumn. In winter the growth of the otolith, as of the fish, is generally in abeyance, one white ring and one dark ring being added to the otolith each year. The otolithic method of determining the age of plaice was introduced by Reibisch in 1899, and the observations of Dr. W. Wallace in England, and of Johansen and other Continental workers, have fully established the value and reliability of this method. This is a matter of much importance in relation to practical fishery problems, since it not only enables a more accurate estimate to be made of the rate of growth of fishes in different regions, but may also throw light upon the effects produced by fishing operations. By this method the great difficulty formerly experienced, owing to the large plaice moving out into deeper water, of obtaining the true average length of the fish at any particular age, has been overcome, and it is now possible to determine what appears to be a sufficiently reliable estimate of the average rate of growth of the plaice in the region investigated.

Prior to the discovery of annual rings in the otoliths of the plaice, the only method of inferring the average rate of growth of fishes was the method of frequency-curves, often known as Dr. Petersen's method, dependent upon the measurement of given-sized groups, and founded on the well-known facts that plaice and other fishes spawn but once a year, and that the spawning season is strictly limited to a definite small period of the year. This has proved a most unsatisfactory and uncertain method, for, as Dr. Wallace points out, "it is impossible to tell whether two successive size-groups are of the same year of age or of two successive years (as the method assumes), or, finally, whether the interval between them is more than one year, since an intermediate year might, for one reason or another, be missing. Now the otolithic method gives us directly *the age of individual* fishes; and not only the average size of an age-group, which, in favourable circumstances (a sufficiently big collection), may be inferred from measurement alone, but also *the range of size*, which it is impossible to infer accurately from the measurements, since the amount of overlapping cannot be certainly calculated."

The otolithic method of determining the age of plaice of different sizes, and the growth-rate of these fishes in different parts of the North Sea and English Channel, is now firmly established as an ideal and accurate method. During the course of the investigations carried out by the association, the age of some 20,000 individual plaice has been determined by an examination of the otoliths, and in each case the length and sex of the fish and the position of its capture have been recorded. The detailed analysis of this great mass of material has, as might be expected, increased our knowledge of the life and habits of this valuable food-fish very considerably, but it is impossible for me in this paper, which is an attempt rather to bring before you a general survey of the work of the association than of one special branch, to deal at all fully with the matter. The results throw much interesting light upon the size and age of plaice at maturity in different regions. Thus it has been shown that in the central part of the North Sea, around the Dogger Bank, female plaice are on the average 40 centimetres (16 inches) long, and the majority just six years old, when they become mature for the first time; while male plaice average 32 centimetres (12½ inches) in length and five years of age, when they first reach maturity. In the southern bight of the North Sea, however, the females reach maturity a year earlier, measuring at first maturity about 33 centimetres (13 inches) in length, and the average age of five years. The average size of plaice at first maturity in the western part of the English Channel appears to be about the same as in the southern bight of the North Sea, but owing to the more rapid growth of the young plaice in the Devonshire bays the corresponding age is about a year less. To quote from the report: "These observations are of importance in showing that the regional differences as to size and age of plaice at first maturity are more extensive and numerous than has hitherto been recognised, and are of interest in connection with the

Hosted by Google

hypothesis of the existence of two races of plaice, a northern and a southern one, in the North Sea." And to quote again: "Such investigations of the age of the plaice population on the fishing grounds are also capable of yielding evidence as to the migrations of plaice, and by means of a series of samples taken along a line proceeding radially from the coast of Holland to the deeper water of the central part of the North Sea, the migration of the small fish from shallow to deep water has been traced. The mass of each age-group was found to move seawards to the extent of several miles between May and September, plaice in their third year taking in September the position which had been occupied in May by those in their fourth year; those in their fourth year in September that of those in their fifth year in May, and so on for the higher ages."

The association's experiments as regards the vitality of trawl-caught plaice point unfortunately to a very high percentage of mortality among the unmarketably small fish. The investigations show that the otter-trawl injures the fish to a greater extent than the beam-trawl, and that fish from a long haul are much less likely to survive than those from a short haul. An hour was estimated as the shortest time likely to elapse between the arrival of the trawl on deck and the shovelling overboard of any small unmarketable fish, under ordinary commercial trawling methods, and in the case of hauls of the beam-trawl, although relatively fewer fish appear to be fatally injured, in only five out of sixteen experiments did so many as 50 per cent. of the small fish appear sufficiently healthy to be likely to survive after return to the sea. With a view to throwing further light on this very serious question of the large destruction of immature marketable fish, experiments have been carried on by enclosing various parts of both commercial otter- and beam-trawls in an outer bag of fine mesh, so as to ascertain what fishes escape through the meshes of the trawl-net. These experiments have shown that relatively few fish escape through the more open-meshed "square" and "batings," or forward portions of the trawl, the bulk of the fish making their escape after reaching the "cod-end," the fine-meshed terminal portion of the trawl-net. The experiments showed that the average sizes at which 75 per cent. of the fishes which reached the cod-end of the trawl were retained by the trawl were as follows:—Plaice, 12 cm. (4·7 inches); dab, 13·5 cm. (5·3 inches); cod, 17 cm. (6·7 inches); whiting, 19·9 cm. (7·8 inches); while 25 per cent. escaped through it.

Very valuable and interesting results have been obtained from experiments carried out under the association by Mr. R. A. Todd, B.Sc., with a view to obtaining information concerning the food of fishes, the contents of the stomachs of some 9,826 specimens of thirty-four species having been examined, classified, and reported on. The results so obtained show that in all fishes examined, and particularly in the case of the plaice, dab, and cod, the young, as compared with the older fish, show a marked preference for crustacea, chiefly consisting of amphipods, cumacea and decapod larvæ for food. An acute competition for food between various fishes probably exists in the case of a few species only, namely, in mollusca, *Solen ensis* and *S. siliqua* (between plaice, dabs and haddock), *Tellina fabula* (between plaice and haddock); in crustacea, *Crangon Allmanni* (between whiting, cod and grey gurnard), *Eupagurus Bernhardus* (between dabs, whiting and cod), etc., etc. It was also shown that a cessation of feeding during the winter months is apparent in the plaice, a habit which may be due to the spawning period of the fish, the number of empty stomachs observed during the winter months being 99 per cent. for November, 72 per cent. for December, 76 per cent. for January, and 57 per cent. for February; while during the remaining months of the year, from March to October, the percentage of empty stomachs in each month never rose above 7 per cent. It is impossible for me to enter deeply into the many interesting points raised by Mr. Todd's reports here, and therefore I can only briefly refer to some of the facts he obtained concerning the chief characteristics of the food of some of the species of fishes examined. Mr. Todd found that the grey gurnard (*Trigla gurnardus*) feeds almost wholly on crustacea, while the latchet gurnard (*T. lairundo*) feeds chiefly on pisces, *Solea lutea* and *Callionymus lyra* being the principal representatives. The angler (*Lophius piscatorius*) is a veritable glutton, one 99 cm. long being found to contain two cod of 45 and 50 cm., three haddock of 21, 22, and 30 cm., and other fish remains.

The cod (*Gadus morrhua*), when quite small ($<$ 15 cm.), feeds wholly on crustacea, chiefly amphipods, but feeds on other food-groups, especially pisces, mollusca, and polychæts, as it increases in size. The haddock (*Gadus æglefinus*) feeds chiefly on mollusca, polychæta, echinoderma, and crustacea, and when young

Hosted by Google

undoubtedly does an enormous amount of damage among small mollusca, no fewer than 509 *Solen* fry of less than 2 mm. length having been counted in one stomach.

As the food of the very large plaice (50 cm. +) consists almost exclusively of mollusca (species of *Solen* and *Mactra*), it is obvious that the presence or absence of large numbers of small haddock will affect the food supply on the feeding-ground, and the number of the larger-sized plaice present. When small (< 10 cm.), the plaice feed chiefly on crustacea (amphipods, etc.) and polychæta. The whiting (*Gadus merlangus*) feeds chiefly on crustacea and pisces; the pout (*G. luseus*) on crustacea, pisces and mollusca; and the ling (*Molva vulgaris*) and turbot (*Rhombus maximus*) entirely on pisces. Soles (*Solea vulgaris*) feed chiefly on polychæta and crustacea, with some pisces and mollusca.

Leaving this interesting international fishery work, we will now consider some of the other investigations that have been accomplished through the Marine Biological Association, investigations which it is not too much to say have been only made possible by the existence of the association's laboratory at Plymouth. Among these investigations, Mr. J. Stewart Thomson's work on the structure and seasonal growth of gadoid and pleuronectoid scales calls for special mention, as bearing on both the scientific and commercial aspects of marine biology. This was a successful attempt on the part of Mr. Stewart Thomson to extend to certain marine fishes a system of age determination by means of the appearance of annual rings on the scales, a system which had already been shown by Dr. Hoffbauer as a reliable means of demonstrating the age of the carp.*

Mr. Thomson's investigations show that scale growth is accelerated during the warmer season of the year, but diminished during the colder season in such a methodic manner as to cause the formation of annual rings. The formation of these annual rings results from the fact that the lines of growth on the scale surface are comparatively widely separated from one another in that portion of the scale formed during the warmer season of the year, but are much less widely separated in that part built up during the colder season. Thus, by following the arrangement of the lines of growth upon certain scales, it is a simple matter to observe the starting-place of any year's growth by the comparatively wide separation of the growth-lines at that portion of the scale, and in this way the surfaces of scales appear mapped out by annual rings. These rings, therefore, supply us with an index as to the age of a fish, and may be roughly compared to the annual rings seen in many trees; while their divergence in growth during the summer and winter is probably due to the effect which seasonal variation of temperature, and more particularly of food supply, has upon the general growth of the fish. Mr. Stewart Thomson's results have been arrived at after the examination of thousands of gadoid scales, and he considers that from an examination of three or four well-developed scales taken from the median region of the flanks near the lateral line, it would be possible to arrive at a very close approximation of the exact age of the fish in ninety-eight cases out of a hundred. The truth of his hypothesis is fully supported by the work of Mr. Cunningham and Dr. Fulton.

Thanks to the systematic dredgings conducted by the association, fair samples of the bottom-deposits, including sands, gravels, pebbles, and small boulders, have been obtained, and have added considerably to our knowledge of the geology of the English Channel; and this subject has been dealt with in an important paper by R. Hansford Worth, published in the Journal of the association.

The experiments of Dr. E. J. Allen and Mr. E. W. Nelson, on the artificial culture of marine plankton organisms, have been crowned with success, and offer an example of pure scientific investigation carried out for the association, which at the same time has important value commercially; adding greatly to our knowledge of the possibilities and successful methods of rearing not only those diatomaceæ peculiar to the plankton, but of the larval-invertebrate and vertebrate forms of life which feed on them, and in turn constitute a large proportion of the food of the marketable marine fishes at certain stages of their lives. As a result of their experiments, Dr. Allen and Mr. Nelson have succeeded in rearing persistent cultures of some eighteen species of plankton diatoms; and their work on this subject has been published in detail in the Journal of the association (New Series, Vol. VIII. No. 5, p. 421–474). One of the greatest charms of marine biology is the way in which each piece of accomplished work opens up new vistas of possible and fascinating investigation. This, I think, I can demonstrate to you by briefly drawing attention to Dr. Allen's paper on "Mackerel and Sunshine," published in

* "Die Altersbestimmung des Karpfen an seiner Schuppe," von Dr. Hoffbauer; *Jahresbericht des Fischerei-Vereins für das Jahr* 1899.

Hosted by Google

Vol. VIII. No. 4, of the Association's Journal. A paper in the same volume of the Journal (Vol. VIII. p. 269), on "Plankton Studies in Relation to the Western Mackerel Fishery," by G. E. Bullen, showed that in the years 1903–1907 there appeared to be a correlation between the number of mackerel taken during May and the amount of copepod plankton, upon which the mackerel feed, taken in the neighbourhood of the mackerel fishing grounds during the same month. From these results, Dr. Allen considered that "it was clearly worth while to consider what conditions favour the production of an abundant supply of copepods in the fishing area, since it appears to be this supply of food which attracts the mackerel into that area, or at any rate into its surface waters." Now it is pretty well established that copepods feed chiefly upon the vegetable organisms of the plankton, while even supposing a considerable proportion of their food were to consist of minute animal organisms, it is obvious that these in their turn would feed upon the phytoplankton. Therefore, to quote Dr. Allen's paper, "it is to the conditions which favour the production of phytoplankton, the fundamental food supply, that we must turn" for enlightenment. "The hydrographical investigations carried out at the mouth of the English Channel have rendered it probable that the movement of the water there is comparatively slow. It may, therefore, be assumed that on the mackerel grounds to the westward of the Cornish coast the water which is present at any particular time has not recently moved into the district from any very remote region, and, treating the matter broadly, has been subjected for some time to the general climatic conditions of the neighbourhood. The question then suggests itself, can the differences which occur from year to year in the abundance of the copepods be referred in any way to such climatic conditions?" After pointing out that the three most obvious matters to be considered in connection with the production of the vegetable plankton are the composition of the sea-water, the temperature, and the amount of light available for the production of plant life; that the only information available concerning the composition of the sea-water refers to its salinity; and that up to the present it has not been possible to show any simple relation between changes in salinity and changes in the animal or vegetable production in the area under consideration, Dr. Allen writes as follows: "Experiments on the cultivation of marine plankton diatoms in the laboratory, upon which I had been engaged, had drawn my attention to the great importance to be attached to the intensity of the light to which the diatoms were exposed. It therefore occurred to me that a special abundance of copepods during the month of May in any year might be due to a special amount of sunshine during the earlier months of the year, which would increase the amount of phytoplankton, the copepod food." The results of Dr. Allen's investigations are fully described in his paper from which I have quoted above, and seem clearly to indicate that a fundamental correlation exists between the abundance of mackerel in May and the amount of bright sunshine during the earlier parts of the year. Indeed, when plotted out, the extreme closeness of agreement between the sunshine curve and the mackerel capture curve is most striking. Mr. A. E. Hefford's observations on teleostean ova and larva is another valuable piece of work successfully accomplished, thanks to the existence of the laboratory at Plymouth; while mention must also be made of Professor J. T. Cunningham's valuable works on "The Natural History of the Marketable Marine Fishes of the British Islands," and his "Treatise on the Common Sole," the former prepared by order of the council of the Marine Biological Association.

Other important work carried out at Plymouth by Dr. Allen has been the investigation of the fauna and bottom-deposits near the thirty-fathom line from the Eddystone Grounds to Start Point; and, in conjunction with Mr. R. A. Todd, of the fauna of the Salcombe and Exe estuaries. The existence of the association's laboratory has enabled investigations to be carried out on the reproduction of fishes, and the life-history and habits of a vast number of marine organisms. Of researches carried out under the auspices of the Marine Biological Association in the Laboratory at Plymouth, or on the North Sea coast from 1886 to 1907, the number published in different scientific journals reached the respectable total of 415.

Such is a brief survey of the history and work of the Marine Biological Association, but I hope that while the time at my disposal has made it impossible for me to do more than lightly touch upon the subject, necessarily leaving many interesting points unmentioned, this outline-sketch which I have had the honour of presenting to you to-night will have illustrated the really vitally important work which the association has accomplished, and the pressing need for the wider support of this institution, that it may in the future be better able to continue and successfully carry out those investigations which

Hosted by Google

are of such importance not only to science, but also to the general community. Under the present conditions the income of the association is never quite sufficient to cover its expenditure on research, and from year to year continuous investigation of both biological and fishery problems has to be scamped, if not brought to an abrupt stop, owing to lack of funds. In the Marine Biological Association of the United Kingdom, equipped as it is for research that will reveal to us the solution of innumerable problems connected with those important fishing industries which constitute the "harvest of the sea," and one of our most important sources of food supply, and will give the answer to many of the enigmas of biology, we have an institution deserving the strongest financial support. Our neighbours across the Channel and our cousins across the Atlantic are ever ready to mock at British apathy towards the advancement of science; and it certainly does seem an extraordinary state of things that we, who pride ourselves on being the greatest maritime nation the world has ever known, do not possess in our capital city of London an oceanographical institute. That is bad enough; but let not our foreign rivals point the finger of scorn at us and say that we cannot even support our Marine Biological Association adequately to carry on its useful and important work.

And now, if you will permit me, I will show you a few of the latest results which I have obtained in the course of my studies of marine animal life, and my application of photography as a means of keeping a graphic record of my biological work. It is rather more than twenty years since, as a student, I first took up photography as a means of keeping a record of microscopical and biological research—chiefly, in those days, with the view of helping my dear father, the late Dr. P. Martin Duncan, F.R.S., in his investigations on the corals and echinoderms. Since then I have had my cameras in almost daily use for the various branches of scientific work in which I have been engaged, so that I am in a position fully to appreciate the very great value of photography as an aid to scientific investigation. The movements of animals have always deeply interested me, and prior to the introduction of celluloid bands, which made the cinematograph an accomplished fact, I began taking serial photographs somewhat on the lines of Professor Marey, using a home-made apparatus, and mounting the results on a kind of zoetrope or "wheel of life"; but with the first introduction of the cinematograph the old apparatus was abandoned. Of the cinematograph results which I am now going to show you, I would particularly draw your attention to those of marine worms, because you will see how very characteristic are the movements of each species represented, and also because it was at the suggestion of Sir E. Ray Lankester that I attempted to obtain them. I am also going to show you the movements of certain marine fishes, crustacea, echinoderms, and molluscs.

DISCUSSION.

The Chairman called attention to the extent to which the various creatures inhabiting the sea had interactions upon each other, and how, accordingly, the life of the sea, or any part of it, must be studied with that fact in mind, and how that was necessary in order to arrive at any real and adequate understanding about it. As the lecture proceeded, it became more and more impressed upon him how futile it was to try to single out any one particular phase of the subject, such as that which concerned the practical aspect regarding food fishes, without considering the matter as a whole. One could not proceed far in a study of the life of food fishes without including in one's purview the whole sea community. The relationship of mackerel to sunshine was a remarkable case in point. Nor could one successfully study the life of one particular part, such as the North Sea, without at the same time making hydrographical investigations into the quality of the water in the Arctic and Atlantic Oceans, because of the slow, intermittent seasonal changes, and the current movements, the bulk of the water sometimes coming from one region, sometimes from another. Amongst the recent work which had been done, he thought the most interesting, and that which was the most profoundly promising, was what Mr. Duncan had not had time to say much about, namely, the work of Dr. Allen in making what were known as "pure cultures" of the microbes which lived in sea water. It was known by the audience, of course, that just as the green vegetation on the land was the ultimate source of all the food supply of the land—a certain number of animals lived on green plants, and other animals lived on these animals, and, however it was traced, the ultimate source of the food was the green plant—so also the ultimate source of all the food upon which fishes lived was the green vegetation, the small things floating on the surface of the sea. And Dr. Allen's investigations into the conditions under which the separate organisms of the sea lived seemed to him to be of the greatest possible promise, not merely towards an understanding of the practical problem of increasing sea fishing, but possibly for increasing the actual bulk of food in the sea, and accelerating the growth of marketable fish. No isolated study was likely to advance the science of marine biology,

Hosted by Google

either practically or theoretically; this object could only be properly attained at a properly-equipped institution containing specialists in the different departments of biology who were working together towards the same end.

Mr. Frank Farnell (late Chairman of the Board of Fisheries, New South Wales) said it had been an intellectual treat to him to listen to the paper and see the slides and cinematograph demonstrations. He had been associated with fisheries in the Australian colonies for a number of years, and though he was not a student of the same character as Mr. Duncan, he recognised the great value of scientific investigation in regard to fisheries generally. Some time ago, when an attempt was made to put trawling on a proper basis in Great Britain, objections were raised by practical fishermen to the proposal, and one reason for the objection was that the process tended to destroy the ova of the fish. But scientific investigation showed that trawling had no effect on the spawn of the fish, because in the case of the majority of the fish in our own waters the spawn was pelagic. So in that one instance, if attention had been paid to the practical experience of fishermen at that time, the great industry of trawling would have had a set-back. The work of scientific men such as Mr. Duncan succeeded in dispelling many clouds of ignorance on the subject. One of the points set out by the lecturer had convinced him of the solution of one of the problems which faced those interested in the matter in New South Wales. They were there anxious to engage in the introduction or acclimatisation of certain species of fish; and for that purpose some kinds were introduced from English waters. They lived in the Australian waters at a temperature of over 70°, though it was anticipated that with anything over 40° they would succumb. But he regretted to say that in inaugurating that experiment, adequate provision was not made by the authorities for the treatment of those fish when they arrived there, and owing to the absence of that provision the fish practically all succumbed. But in the last few years flounders had been introduced from Tasmania. His contention had always been that it might be all very well to engage in introducing new species of fish, but if it was at all possible, those fish thus introduced would probably find their way back to the region from which they were originally brought. The fish which were introduced from Tasmania in the gravid state, after hatching their ova at the marine biological station there, were found 100 miles lower down than Sydney. That seemed to be the extent of the region of their distribution from Tasmania. They had not only been liberating the adult flounders after collecting the spawn from them, but had liberated hundreds of millions in the "fry" stage; and there had not been any instance in the last seven or eight years showing that those fishes, either adult or fry, had remained in the regions of the Sydney waters. These experiments were of very great value in proving to the world what were the migratory habits of the different fish. His belief was, in connection with the introduction of the Tasmanian flounder to New South Wales waters, that directly they got free they returned to the district to which they properly belonged. In conclusion, he desired to express his keen appreciation of the paper, which would prove of great interest and value to the Fisheries Board of New South Wales.

The Chairman formally moved a vote of thanks to Mr. Martin Duncan for his extremely valuable paper, and the beautiful illustrations. It was unnecessary to comment upon them; they constituted their own justification.

The vote was unanimously carried.

Mr. Duncan, in acknowledging the vote, said that if he had succeeded in awakening a keener interest in the Marine Biological Association and its valuable work, he would feel that his efforts had been amply rewarded.

EMPIRE NOTES.

Chambers of Commerce of the Empire.—The proposed Congress of British Chambers of Commerce, which is to be held in London in June, will be an important gathering. The arrangements for it are being made by the British Imperial Council of Commerce, which was formed in June last, and on which the leading Chambers of Commerce of the Empire are represented. Over 500 delegates are expected to attend from all parts of the Empire. The main object of the meeting will be "to focus the views of the whole of the Chambers of Commerce of the Empire on matters of common interest, and to get public opinion to bear upon Governments in favour of various matters and reforms which the business men of the Empire consider necessary to its material prosperity and development." Among the subjects to be considered will be Penny Postage throughout the Empire; the "All-British" cable; the question of double income tax on investments at home and in the Dominions; commercial arbitration; preferential trade; national defence; emigration, and the Panama Canal. The last-named subject is one of special importance, as the conditions under which that waterway between the Atlantic and Pacific Oceans may be used will have an important bearing upon the commercial intercourse of the Empire.

Transatlantic Mail Service.—The mail contract, entered into by the Canadian Government in 1906, expires on May 1st of this year. Rumours are afoot regarding the terms upon which the new contract will be made. The late Dominion Government were in favour of the abolition of a direct subsidy during the summer months, and many of the leading steamship lines, finding that it pays to run fast vessels between the Mother Land and

Hosted by Google

Canadian ports, would be willing to carry the mails, on a payment equal to a slightly advanced freight rate. The new Government, however, is making an attempt to bring about the much-talked-of "all-red route" service, an initial step in the direction of which would involve the subsidising of steamers, as fast as, if not faster than, those now running. An adequate subsidy for this purpose would cost the Dominion Government at least £800,000 per annum, instead of £120,000 as at present. It has been suggested that, in order to secure the adoption of this desirable service, the Home Government should join in the subsidy, but the likelihood of their doing so is extremely remote. It is argued that with the existing rate paid to the shipping companies, it would be impossible to get capitalists to interest themselves in providing an accelerated service. Whatever may be the outcome of the new proposals, it is certain that the present Canadian service is in need of numerous improvements. There is, surely, no reason why Canada should not have as effective a mail service as that which exists between Great Britain and the United States.

Canadian Contracts for British Firms.—Two large contracts have been recently given to British contractors, the value of one being £1,500,000 sterling, and the other is also over a million. This fact is of some interest, in view of the growing tendency to suggest that British tenderers are unduly handicapped in competing with local organisations. An English trade journal has been vigorously attacking the system of contract awards, asserting that there is a lamentable lack of fairness. Something is known in this country of local influences and prejudices in the element of contracts, and it is not to be expected that the same element will not appear in Canada. Owing, however, to the lack of skilled labour and the high wages paid in the Dominion, British contractors have a better chance of securing many of the large contracts than the Canadian firms themselves. Up to the present, the chief rival of Britain has been the United States, where a careful study of Canadian opportunities has been made. Hitherto, several wealthy British engineering firms have allowed many excellent opportunities to pass. It is to be hoped, however, that in future, greater attention will be paid to the opportunities offered to British manufacturers by the rapid development and increasing requirements of Canadian trade.

The Prosperity of Newfoundland.—At the opening of the Legislature of Newfoundland last month, the Governor congratulated the Colony on its unexampled prosperity. Every effort has been made during the present administration to improve the fisheries, roads and steamship services, and steps have been taken to enlarge the old age pension scheme for ameliorating the condition of the people. The Premier reports that there was a handsome surplus for the last fiscal year. With this surplus the Colonial Treasurer hopes to make greater strides to combat tuberculosis by the establishment of further and better equipped sanatoria. One of these institutions is located in St. John's, and there are sixteen others in various parts of the Island. These sanatoria are the gift of the Reid Newfoundland Company, and are maintained out of the public purse. Good fisheries, high prices of exports, all-round progress in mining, farming and manufacturing industries, were indicated as the factors in bringing about a state of affairs which is altogether satisfactory.

The Design for the Federal Capital.—A difficulty has arisen in securing designs for the new Australian capital, owing to the conditions imposed by the Government in relation to the competition. These require that the plans go before a committee of one engineer, one architect, and one surveyor, whose names, however, are not given, and who therefore, in the judgment of the Architectural Institutions of Australia, Europe, and America, might mean anybody. It has been suggested that a board should be appointed, consisting of three architects, one each for the British, United States, and Australian Institutes, to act, with engineers and surveyors, as judges. It is argued that an architect who competed would be put to great trouble and expense in preparing his design, and that he would require to be assured that those who are entrusted with the duty of dealing with the matter were competent for the work. Owing to the practical boycott of the leading architects of the above countries, only twenty designs have thus far been received. To meet the difficulty the Australian Minister for Home Affairs is arranging for a consultation between the Institutes, which, it is hoped, will lead to a revision of the conditions, and so enable a larger number of leading architects to compete.

Australian Fruit Industries.—The Government of New South Wales propose to establish fruit-canning, vegetable-canning, and jam-making factories in the Burrinjuck irrigation area on the Murrumbidgee. At these factories the produce of the settler will be handled at moderate rates and, subsequently, the factories may be taken over by the settlers themselves, under a co-operative arrangement. The experiment will be carried on by the Department of Agriculture. The fruit-growers will be encouraged to plant only the best varieties of fruit, and will be taught how to specialise in those varieties that are most useful for canning purposes. The Burrinjuck scheme of irrigation will bring under intensive cultivation no less than 350,000 acres of splendid land. It is stated that 500 irrigation farms in this area will be available for settlement in April. A similar proposal is under consideration in Victoria, in the well-known and fertile Bacchus Marsh irrigation district. The Commissioner is endeavouring to induce landowners in that district to sub-divide their properties for intensive cultivation, and

Hosted by Google

suggests that a canning department be added to one of the district butter factories, for preserving the fruit raised by the settlers.

The Expansion of Trade in New South Wales.—The figures regarding the growth of manufactures and trade in New South Wales indicate that the year 1911 has shown a considerable advance upon former years. At the end of 1911, the number of factories was 4,823. Over 99,000 hands were employed, and goods valued at nearly £50,000,000 were manufactured. The value of the production, being the value added to raw materials, exceeded £17,000,000, an increase of £2,300,000 in the year. Increases are shown in almost every commodity. The butter produced amounted to 76,624,830 lbs. The New South Wales Government railways carried nearly 34,000,000 passengers during the half-year just ended, and 5,500,000 tons of merchandise. The net earnings of the railways for the period mentioned were £1,185,472, while the gross revenue reached £3,259,139. The State has 3,807 miles of railways open to traffic. The tramway system of New South Wales at the end of December last had 191½ miles open for traffic, and the gross revenue was £752,056. The net earnings were £113,503. The number of passengers carried was 127,336,793. The growth of railways and railway traffic is one of the surest signs of a country's increasing development, and the railway returns are satisfactory in every way. At the commencement of this year the shortage of labour was acutely felt, and at the moment the demand for skilled artisans in Sydney and other towns is pressing. To supply this lack, efforts are being made to obtain men from the United Kingdom, but owing to the want of adequate shipping accommodation there is no immediate prospect of the need being supplied.

Irrigation in South Africa.—This subject was dealt with in a paper by Mr. W. A. Legg, which appeared in the *Journal* of February 9th, and reference was also made to it in these columns last month. Information is to hand that a successful experiment, in the direction of transforming the arid Karoo into fertile farming land by means of irrigation, has been conducted at Hanover, where a stretch of level ground, comprising many acres, was ploughed and sown at the beginning of the season, an arm of the Seacow River, running through the district, having been diverted so as to flood the area. No less than 40,000 bundles of wheat and other cereals were harvested, as a result of the experiment. Following up this experiment, the Union Government has privately purchased several thousands of acres of land south of the Aughrabis Falls, on the Orange River, and also land on the north of the Falls, at a total cost of £15,000. At the moment nothing definite is known as to the purpose which prompted this action, but the general impression is that the ground will be used for irrigation purposes.

Asiatic Trading Licences in Rhodesia.—Throughout South Africa, British traders have been attempting, for many years, to eliminate the small trading operations of the Asiatics. The first great blow to these natives of India and China was the Eight Hours' Shop Act. This Act had the effect of putting half the Asiatic trading population out of employment, and ended in their return, in large numbers, to their native countries. Since that time it has become law that no coloured man can trade without a licence. An interesting case recently occurred at Buluwayo, where the town council refused to grant a trading licence to a certain Asiatic. Sir William Milton, the Administrator, reversed the decision, and a considerable amount of unfavourable comment was consequently called forth. Feeling is exceptionally strong throughout Rhodesia upon the question of licences, as it is held that the trading methods of Asiatics conflict with the popular sense of what is good for the community. The Buluwayo town council recently issued a warning to householders against the dangers of consuming commodities purchased from Indians without taking precautionary measures, and it was further suggested that the time had arrived for the total abolition of hawking. It is likely that an amendment of the law in this direction will be made.

CORRESPONDENCE.

THE SVASTIKA.

May I make amends to Sir George Birdwood for my levity by offering two other instances of the universal right-handedness, not mentioned by him? There lies before me a photograph by that learned photographer Mr. R. Welch, of Belfast, of the Cloca Breaca altar and "cursing stones" at Inishmurry, Sligo, Ireland. Mr. Welch told me the peasants used these to curse their enemies by walking round the altar contra-clockwise and turning each of the cursing stones on it, also left-handedly, while repeating the Pater Noster backwards. This requires great care, as any mistake would recoil disastrously on the curser. The largest of these stones, on the left-hand near corner, is inscribed with marks which, so far as appears from this one point of view, may well be a left-handed *svastika* and the signs of the zodiac.

The other instance is the universal use of right-handed screws, save in the rare cases where a special reason requires them to be left-handed.

R. T. Mallet.

Perhaps some of your readers may be interested in knowing that in reverence for the *svastika* the Chinese are not behind their Western neighbours. And possibly some of the Sinological members of the Society may give us fuller information on the use of the *svastika* in the extreme Orient. I

Hosted by Google

remember reading somewhere that its employment as an ornament, either in metal or on embroidery, is one of the deadly sins, ranking with murder in wickedness.

W. H. SHOCKLEY.

NOTES ON BOOKS.

GOVERNMENT OF FORMOSA. Report on the Control of the Aborigines in Formosa. Bureau of Aboriginal Affairs. Taihoku, Formosa.

To all who appreciate the present powerful position of Japan between the Old World and the New, I would say—read this book. There are but forty-two pages of it; but the subject of them, and the way in which it is treated, and in which it is further illustrated by no less than one hundred photographs, and three maps, and three diagrams, and four statistical tables; and the paper, printing, binding, and general "forwarding" of the book, to the very monogram on its titlepage, are a prophecy of assured fulfilment—for all habituated to the handling of official administration reports—that, astonishing as is the greatness of Japan in the present—from the fateful February 8th, 1904—it will be found yet more marvellous and momentous in the future—and so long as it is justified and reinforced by righteousness and truth.

The Island of Formosa, perhaps first generally known to Europeans through the impostor George Psalmanazar's forged "History of Formosa," 1704, is about 225 miles in length, and 90 miles in breadth at its broadest, its whole eastern side being mountainous and virgin forest, from its prolonged southern extremity to within twenty miles of its rounded northern end; and draining off all its considerable streams through its western side into the sea; out of which the island rises in a series of terraces to the mountains, giving to the island its Chinese name of Tai-wan, *i.e.* "Terraced-beach." This western coast was partially settled by the earlier Spanish and Dutch adventurers into the Yellow Sea; but they were all expelled from it in the latter half of the seventeenth century by the Chinese, who, extending themselves through the lowlands, drove the aborigines back into their highland strongholds. The island was ceded to Japan in 1894; and the present Report deals with the control of these aborigines from that date to November, 1909. They occupy the whole mountainous eastern side of the island, from within seven miles of South Cape to within ten miles of Taihoku, the Japanese capital, situated about ten miles from the sea, on the north, where the semi-civilised lowland portion of the island extends continuously, with a breadth of about twenty miles, for thirty-five miles down its eastern side. The area of Formosa is in this way almost equally divided lengthwise, between its semi-civilised and its still more or less untamed autochthonous inhabitants. The latter population numbers 121,981 souls, in 683 villages: of which total the Ami, scattered over an average breadth of twelve miles, and a length of eighty-five miles, down the steep eastern coast, number 31,578, centred in 108 villages; and the Tai-yal, occupying nearly the whole northern half of these alpine wilds, 28,242, in 242 villages. The only other great tribes of the nine tribes named, are the Bunun, west of the Ami and south of the Tai-yal, counting 15,807 in 100 villages, and the Tsarisen, west of the Bunun, 13,995 in fifty-five villages. The Tai-yal are absolute savages; the Bunun and the Tsarisen are but little better; but the rest are gradually becoming more peaceful in their ways and means of life, and though they still hunt and fish they are also steadily taking more and more to agriculture and cattle-breeding. The Tai-yal tattoo their faces, and practise head-hunting as a religious rite. A human head is required at the opening of every public ceremony, and when a dispute occurs between two tribesmen, the decision is given in favour of the one who first secures a human head; and again, on a Tai-yal youth attaining his majority he has to bring in a human head, and now, preferably, of a Japanese, before he can be consecrated a member of the tribe. The Japanese are proceeding in their task of raising these primeval savages higher in the scale of humanity very much on the same lines as we have been following for a century past with the wild tribes of Central and Southern India,—in patience and quietness, and with equal steadfastness and sagacity, and the most merciful forbearance; only, as in all else they do, in this also, they seem to be more thoroughgoing than ourselves, judging from the greater success of their efforts, and probably because these are more scientifically directed. At least they never allow mercy to be degraded to sentimentality; never paltering with lawlessness and violence. One of their great "means of grace" in the art, or rather, the religion of civilisation, is in laying down roads everywhere. They have run a railway from the extreme north-east of the island, all down its western side to within thirty miles of South Cape; and a "trolly-road" right through the Ami country, from Karenko on the north to Taito on the south. But their most successful feat has been in establishing "a guard line" between the semi-civilised, and, under their direction, the increasingly civilising western side of the island, and its still wildered eastern side; and also between the murderous Tai-yal tribe, and the other more progressive aboriginal tribes.

And the book itself stands out so stridently for a wonder and a sign! To begin with, it is, speaking of its mere material substance and structure, but a "Blue Book," or a "Yellow Book," and of the Government of Japan. Yet it is written in English, and pure, simple, and clear English, and although printed and published at Taihoku, a place-name English people have never heard of before, it is perfect in its paper, in its typography, and its "get up"; in everything that constitutes it *un livre de bonne foi*, as the French so expressively say. In its maps and photographs it is equal

Hosted by Google

to anything we do with such official publications, in England, and in its binding far superior to any of our bindings of to-day of any class of utilitarian books. Except in its maps, it is superior in every detail to what we have as yet done in India, even at Bombay, and Calcutta, and Madras; and I can only compare it as a sample—and an example!—with the volume on "Farm Weeds" recently issued by the Government of Canada and reviewed by me in our *Journal* of December 1st last. The monogram on the titlepage is of two equilateral triangles placed base to base, with the upper one open at the apex, like the "triangle" used in military bands, the whole wreathed in with two sprays of chrysanthemum. Mr. I. Tokugawa, the Attaché to the Japanese Embassy, has most courteously informed me that it is not only a symbol, but a Chinese "character," Tai, the first syllable of the Chinese [and Japanese] name, Tai-wan, of the Island of Formosa. It is a charming monogram. The book is indeed an omen; and a most portentous one, when you know that the same perfection of workmanship is shown by the Japanese in all to which they ever put their hands, from the imitation of English books to the reproduction of English warships.

GEORGE BIRDWOOD.

KÖNIGLICH-SÄCHSISCHE PORZELLANMANUFAKTUR, MEISSEN. By Dr. K. Berling. Meissen: The Royal China Manufactory. £2 or $10.

China has been manufactured in the country whose name it bears for upwards of a thousand years, but it was not until early in the eighteenth century that the problem of making pure white porcelain was solved in Europe. At that time Friedrich August I., generally called August the Strong, was Elector of Hanover; he was possessed of a great thirst for knowledge and a laudable passion for encouraging the arts and manufactures of his country. When he heard of the fame of young Johann Friedrich Boettger, who was gaining a great reputation as a chemist or alchemist, he sent for him. For some reason or other Boettger fled, but in 1701 he was caught and brought to Meissen. The rumours that he had found the philosopher's stone and the art of making gold proved to be ill-founded; but such was his success in manufacturing, first, earthenware pottery and afterwards pure white china, that in 1710 the Elector decided to found a factory in Meissen over which he appointed Boettger to rule supreme.

Such was the origin of the famous factory which for two centuries has continued to supply the world with Dresden china. During this long period there have naturally been many ups and downs—periods of great success, and periods of disaster—but the factory has contrived to weather all storms, and in 1910 it celebrated the two hundredth anniversary of its foundation. On this occasion Dr. Berling was invited to write a history of the factory, and this sumptuous work is the result. It consists of some 190 folio pages, which relate the history of the factory and contain careful descriptions of many of the works produced. To the expert in china one of the most valuable features of the book lies in the fact that Dr. Berling has for the first time traced a great many of the best-known pieces to the artists who made them. Another admirable feature is the 377 illustrations which were prepared under the supervision of Professors Hoesel and Achtenhagen, and which give a complete pictorial history of Dresden china. Mention should also be made of the chapter on the chemico-technical working of the factory by Dr. Heinze, and the sketch of the organisation, financial management and social statistics of the royal china factory by Privy Counsellor of Commerce Gesell.

The edition before us is in English—a compliment which has presumably been paid to this country because of the numerous patrons it has provided to the factory. Upon the whole the translation has been well done, but it is marred by a good many obvious, if unimportant, slips, which could have been easily corrected by an English eye. One does not, however, wish to cavil at these; one prefers to look at the work as a whole, and to congratulate the Meissen factory and Dr. Berling upon having given us a worthy memorial of a great occasion.

GENERAL NOTES.

ACCIDENTS IN COAL MINES.—In reply to a question asking how many workmen were killed or injured in the coal mines of the United Kingdom during each of the past ten years, the Home Secretary has furnished the following figures:—

Year.	Number killed.	Number injured as reported to the Inspectors.	Number injured and disabled for more than 7 days.
1902	1,024	3,745	—
1903	1,072	3,822	—
1904	1,055	3,754	—
1905	1,159	3,646	—
1906	1,142	3,839	—
1907	1,245	5,892	—
1908	1,308	5,860	141,851
1909	1,453	5,859	153,306
1910	1,775	5,737	159,042
1911	1,259	(Not yet available.)	

The figures in the last column were obtained for the first time in 1908 under the provisions of the Notice of Accidents Act, 1906, and cannot be

Hosted by Google

given for the preceding years. The table speaks eloquently of the terrible dangers of the collier's life. On an average some four men are killed every day, and five hundred disabled for more than seven days.

CANADA'S RAILWAY PROGRAMME, 1912.—Railroad construction last year in Canada reached high-water mark, nearly 2,000 miles of new railway having been built. Canada's total railway mileage has thus been brought up to 26,500 miles. The building programme for the present year seems to insure as great, if not greater, activity. Sir Thomas Shaugnessey states that the Canadian-Pacific Railway will probably build five to six hundred miles of new track, and that the main line from Medicine Hat westward for 500 miles is to be double tracked. The company will thus secure a double line of railway from the head of Lake Superior to the Rocky Mountains, a distance of 1,200 miles. The Grand Trunk Pacific contemplates building 1,100 miles of railway, 200 of which will represent the main line in British Columbia and the balance branch lines in the prairie provinces. The Canadian Northern will spend a million sterling on their system in British Columbia, in addition to a large expenditure on their main line north of Lake Superior, for the completion of which they raised the huge loan of nearly seven millions sterling in London at the close of last year.

"SHAKESPEARE'S ENGLAND" EXHIBITION.—This exhibition, promoted and organised by Mrs. George Cornwallis-West in support of the Shakespeare Memorial Fund, will be held at Earl's Court from May to October. Inside the permanent buildings and in that portion of the grounds known as the Queen's Gardens will be erected a replica of an English town of the sixteenth century, with streets lined with houses of characteristic Elizabethan architecture. These houses will be available as shops for the use of firms of high standing. Performances will be held in a replica of Shakespeare's own theatre, the "Globe," while a copy of the old "Fortune Theatre" will be given up to folk-songs and Morris dances.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at 8 o'clock:—

MARCH 27.—THEODORE E. SALVESEN, "The Whaling Industry of To-day." LORD SANDERSON, G.C.B., K.C.M.G., will preside.*

APRIL 17. — JOHN HENRY COSTE, F.I.C., "Municipal Chemistry." DR. RUDOLPH MESSEL, F.R.S., will preside.

APRIL 24.—GEORGE FLETCHER, "Technical Education in Ireland."

MAY 1. — WILLIAM BURTON, M.A., F.C.S., "Ancient Egyptian Ceramics."

MAY 8.—E. D. MOREL, "British Rule in Nigeria."

MAY 15. — ERNEST KILBURN SCOTT, Assoc. M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere." SIR WILLIAM RAMSAY, K.C.B., Nobel Laureate, F.R.S., will preside.

MAY 22. — GORDON CRAIG, "Art of the Theatre." MISS ELLEN TERRY will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 o'clock:—

APRIL 25.—SIR JOHN O. MILLER, K.C.S.I., "The Central Provinces."

MAY 16.—NEVILLE PRIESTLEY, Managing Director, South Indian Railway, "Indian Railways."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 o'clock:—

MARCH 26.—LEONARD LOVEGROVE, "British North Borneo." * EARL BRASSEY, G.C.B., will preside.

MAY 7.—ALAN BURGOYNE, M.P., "Colonial Vine Culture."

MAY 21.—THE HON. J. G. JENKINS, "Australian Railways."

CANTOR LECTURES.

Monday evenings, at 8 o'clock:—

NOEL HEATON, B.Sc., F.C.S., "Materials and Methods of Decorative Painting." Three Lectures.

Syllabus.

LECTURE II.—MARCH 25.—*Fresco and its Modifications.*—The nature of plaster—Chemistry of fresco process—Practical details—Quality of the result—Limitations—Nature and selection of pigments—Problem of durability—Protection of surface—Modifications of the process—Fresco-secco — Stereochrome — Keim's process — Oxy-chloride process—Possibilities of development.

LECTURE III.—APRIL 1. - *Oil and Tempera Painting.* — Tempera: technical principles on which it depends—Nature and use of natural and artificial emulsions—Yolk of egg—Casein, etc.—Protection of the surface—The problem of varnishing. Oil painting: the technical principles on which it depends—Its scope and facilities—The question of durability—Limitations as regards ground—Modifications of oil painting—Use of wax—Spirit fresco—Resins and varnishes—Oil tempera.

HOWARD LECTURES.

Monday evenings, at 8 o'clock:—

CAPTAIN H. R. SANKEY, R.E., M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

April 29, May 6, 13, 20.

* These papers will be illustrated by lantern views and by the cinematograph.

Hosted by Google

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 25...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Noel Heaton, "Materials and Methods of Decorative Painting." (Lecture II.)

Geographical, Burlington-gardens, W., 8.30 p.m. Mr. D. Carruthers, "Exploration in Central Asia."

Actuaries, Staples Inn Hall, Holborn, W.C., 5 p.m. Messrs. W. Palin Elderton and R. C. Fippard, "Notes on the Construction of Mortality Tables."

Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Mr. C. F. A. Voysey, "Patriotism in Architecture."

TUESDAY, MARCH 26...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Mr. Leonard Lovegrove, "British North Borneo."

Sociological, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8.15 p.m. Annual General Meeting.

Swedenborg Society, at the Suffolk-street Galleries, Pall Mall, S.W., 7.30 p.m. Professor Sir W. F. Barrett, "Swedenborg's Philosophy in the Light of Modern Science."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. T. R. Holmes, "Ancient Britain." (Lecture III.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on Papers. (*a*) Messrs. A. B. McDonald and G. M. Taylor, "The Main Drainage of Glasgow"; (*b*) Mr. W. C. Easton, "The Construction of the Glasgow Main-Drainage Works"; (*c*) Mr. D. H. Morton, "Glasgow Main Drainage: the Mechanical Equipment of the Western Works and of the Kinning Park Pumping-Station." 2. Messrs. E. L. Mansergh and W. L. Mansergh, "The Works for the Supply of Water to the City of Birmingham from Mid-Wales."

Photographic, 35, Russell-square, W.C., 8 p.m. Messrs. J. and E. Rheinberg, "The Micro-Spectra Method of Colour Photography by Prismatic Dispersion."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mr. J. A. J. de Villiers, "The Boundaries of British Guiana."

Faraday Society, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8 p.m. 1. Mr. S. W. Melsom, "Dry Batteries: the Relation between the Incidence of the Discharge and the Relative Capacity of Cells of Different Manufacture." 2. Dr. R. B. Denison, "Contributions to the Knowledge of Liquid Mixtures." (Parts I. and II.) 3. Messrs. L. S. Bagster and B. D. Steele, "Electrolysis in Liquefied Sulphur Dioxide." 4. Dr. A. C. Cumming, "The Elimination of Potential- due to Liquid Contact." Part II. 5. Messrs. E. P. Perman and T. W. Price, "Vapour-Pressure of Concentrated Aqueous Solutions."

Quekett Microscopical Club, 20, Hanover-square, W., 8 p.m.

WEDNESDAY, MARCH 27...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Theodore E. Salvesen, "The Whaling Industry of To-day."

Geological, Burlington House, W., 8 p.m.

Naval Architects, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C. (Annual Conference), 11.30 a.m. 1. Address by the President. 2. Admiral Sir Reginald Custance, "Some Military Principles which bear on Warship Design." 3. Professor W. Hovgaard, "On Turning Circles." 4. Dr. T. E. Stanton, "The Law of Comparison for Surface Friction and Eddy-making Resistances in Fluids." 5. Mr. G. S. Baker, "Description of the William Froude National Tank." (Part II.)

Royal Society of Literature, 20, Hanover-square, W., 5 p.m. Mr. T. S. Moore, "The Best Poetry."

St. Paul's Ecclesiological Society, Chapter House, St. Paul's, E.C., 8 p.m.

Economics and Political Science, London School of, Clare-market, Kingsway, W.C., 7.15 p.m. Mr. Harold Jeans, "The Economics of the Iron Trade." (Lecture II.)

THURSDAY, MARCH 28...Naval Architects, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C. (Annual Conference), 11.30 a.m. 1. Mr. W. I. Knudson, "Results of Trials of the Diesel Engined Sea-Going Vessel 'Selandia.'" 2. Mr. A. C. Holzapfel, "Gas Power for Ship Propulsion." 3. Messrs. George Idle and G. S. Baker, "The Effect of Bilge Keels on the Rolling of Lightships." 4. Mr. A. Cannon, "Results of Calculations regarding the Effect of an Internal Free Fluid upon the Initial Stability and the Stability at Large Angles in Ships of Various Forms."

7.30 p.m. 1. Monsieur G. Hart, "On the Solignac-Grille Boiler and its Application in French Channel Steamers." 2. Mr. Harold E. Yarrow, "Results of Experiments on Water-tube Boilers, with Special Reference to Superheating."

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Child Study Society, 90, Buckingham Palace-road, S.W., 7.30 p.m. Miss Beatrice Edgell, "The Experimental Study of Memory."

Chemical, Burlington House, W., 4.30 p.m. Annual General Meeting. Presidential Address by Professor P. Frankland, "Some Stereochemical Problems."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. F. A. Dixey, "Sexual Dimorphism in Butterflies." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. W. Mark Webb, "The Uses of Colour to Animals."

Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Dr. J. A. Fleming and Mr. G. B Dyke, "The Power Factor and Conductivity of Di-electrics when tested with Alternating Electric Currents of Telephonic Frequency at Various Temperatures."

FRIDAY, MARCH 29...Naval Architects, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C. (Annual Conference), 11.30 a.m. 1. Professor J. H. Biles, "Geared Turbine Channel Steamers, 'Normannia' and 'Hantonia.'" 2. Monsieur P. Sigaudy, "Performance on Service of the Channel Steamer 'Newhaven.'" 3. Mr. F. R. S. Bircham, "On the Measurement and Automatic Recording of Dead Reckoning." 4. Commander G. J. Baugh, "Description of a Tide Indicator."

7.30 p.m. 1. Mr. A. Welin, "The Arrangement of Boat Installations on Modern Ships." 2. Dr. L. Gumbel, "Torsional Vibrations of Elastic Shafts of any Cross Section and Mass Distribution, and their Application to the Vibration of Ships." 3. Professor W. E. Dalby, "Load Extension Diagrams obtained Photographically with an Automatic Self-contained Optical Load-extension Indicator."

Royal Institution, Albemarle-street, W., 9 p.m. Professor Sir J. J. Thomson, "Results of the Application of Positive Rays to the Study of Chemical Problems."

SATURDAY, MARCH 30....Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Molecular Physics." (Lecture VI.)

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,097. VOL. LX.

FRIDAY, MARCH 29, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, APRIL 1st, 8 p.m. (Cantor Lecture.) NOEL HEATON, B.Sc., F.C.S., "Materials and Methods of Decorative Painting." (Lecture III.)

Further details of the Society's meetings will be found at the end of this number.

COLONIAL SECTION.

Tuesday afternoon, March 26th; EARL BRASSEY, G.C.B., in the chair. A paper on "British North Borneo" was read by MR. LEONARD LOVEGROVE.

The paper and discussion will be published in a subsequent number of the *Journal*.

CANTOR LECTURE.

On Monday evening, March 25th, MR. NOEL HEATON, B.Sc., F.C.S., delivered the second lecture of his course on "Materials and Methods of Decorative Painting."

The lectures will be published in the *Journal* during the summer recess.

CONVERSAZIONE.

The Council have decided that the Society's Conversazione shall in future be held biennially instead of annually, and that no Conversazione shall be held this year.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, March 14th, 1912; SIR THEODORE MORISON, K.C.I.E. (Member of the Council of India), in the chair.

THE CHAIRMAN announced that, as Mr. Gait was still in India, Mr. J. D. Anderson, I.C.S. (retired), had kindly undertaken to read the paper. He would point out that the paper represented only a few of the first-fruits of Mr. Gait's Census Report. A great deal of the most interesting matter—that which related to anthropological researches — was not indicated in it; for that they had to wait for t full report.

The paper read was—

THE INDIAN CENSUS.

By E. A. GAIT, I.C.S., C.I.E.,
Census Commissioner for India.

INTRODUCTORY REMARKS.

When I was asked to read a paper on the Indian Census taken on the 10th March, 1911, my first impulse was to suggest that the task should be entrusted to the more experienced hands of my old friend and mentor, Sir Athelstane Baines, who, as Census Commissioner for India in 1891, gave me my first lessons in census taking, and who since then has achieved well-earned distinction in a wider statistical arena. I reflected, however, that great changes have occurred during the last twenty years, both in local conditions and in certain branches of census procedure, and my intimate connection with the last two censuses seemed, therefore, to afford some justification for my attempting the task.

It is barely a year since the census was taken. Some of the final tables are still incomplete, and none of the provincial reports have yet been sent in. It is, therefore, impossible, at this stage, to deal at all with certain branches of the subject, such as migration, caste, and occupation; and even where the bare figures are available, it would be unsafe to build too large an edifice on them until they have been subjected to a more detailed examination than has hitherto been found possible. I propose, therefore, in this paper to confine myself to a presentation of the main features of the statistics, and a discussion of the

Hosted by Google

broad conclusions to be drawn from them. At the time of writing, the revision of provincial boundaries, in accordance with the changes announced at Delhi by His Majesty the King-Emperor, has not been finally settled. In the two Tables A and B appended to this paper, I have, therefore, given the main statistics for the provinces as constituted at the time of the census.

Previous Censuses.

Although in some provinces it had long been the practice to make periodic estimates of the population, the first attempt to do so throughout India was carried out in the years 1867 to 1872. But even then the census was non-synchronous; the methods followed in different parts were far from uniform, and the information collected and tabulated varied from province to province. The first synchronous census on a uniform plan was taken in 1881. The arrangements for it were made by the late Sir Charles Elliott, who was the first to hold the appointment of Census Commissioner for India. He took up the work with his characteristic energy and thoroughness, and although the procedure has been steadily improved at successive enumerations, it still follows the general lines which he laid down thirty years ago. Sir Charles was transferred to a higher appointment before the operations had been completed, but he never ceased to take a close personal interest in the subject, and seven years ago he read before this Society a most interesting paper on the census of 1901. Since 1881 a general synchronous census has been taken every ten years.

The Arrangements for taking the Census.

In India, with its teeming population, its great distances, and its varied local conditions, a census presents difficulties which can only be overcome by careful organisation and a judicious combination of close supervision and decentralisation, and in particular by the creation of a complete and well-drilled graded staff, the officers in each grade being carefully linked up with those above and below, so as to provide a ready ladder of communication between the top and the bottom of the structure. As on previous occasions, the District Officer was responsible for the arrangements in his district, and the Tahsildar, Sub-Inspector, or Township Officer, for those in his tahsil, thana, or township. Each tahsil, etc., was divided into circles under supervisors, and each circle into blocks containing forty to forty-five houses, under the enumerators who actually took the census. The total number of supervisors and enumerators was about two millions.

Owing to the widespread illiteracy of the population, the schedules in India (with a few exceptions) are filled in, not by the householders, but by the enumerators. In the first instance, classes were held at which each grade of census officer was trained by some officer of a higher grade. A rough draft of the census record was prepared by the enumerators a few weeks beforehand for all persons ordinarily residing in their blocks. This was carefully checked by the supervisors and other superior officers, and was then copied into the schedules. On the night of the census the record was brought up to date by striking out the entries relating to persons no longer present, and filling in the necessary particulars for new-comers. Some errors, of course, remained—chiefly in the age column—but, on the whole, thanks to the careful preliminary training and the subsequent examination of the schedules, it may be said that the work was well done. The entries, at any rate, were, as a rule, more accurate than those made by the limited number of private persons (chiefly Europeans) who filled in the schedules for themselves and their families. In the latter, owing to failure to read the instructions, numerous errors came to light. A High Court judge, for instance, included in his schedule a relative who was absent for a few days, and who was thus enumerated twice over, while an hotel-keeper and his wife put themselves down on a single line, noting "2" as their serial number, and "actual work" as their occupation. One old spinster, thinking, perhaps, that she was at last signing the marriage register, entered "full age," instead of the actual number of years she had lived; and another, seeing an insult in the question "whether able to read and write," instead of a simple "Yes," wrote "perfectly well educated." The superiority of the work done by trained enumerators to that of individual householders is now so well established that the tendency is to discourage the issue of private schedules, even to Europeans, and, as far as possible, to get the whole record prepared by the enumerators.

The Provisional Totals.

The efficiency of the organisation is shown by the great speed with which the provisional totals were got in. According to the instructions, each enumerator on the morning after the census was to prepare a statement showing the population of his block, and hand it to his supervisor,

Hosted by Google

who, after checking it, was to prepare a total for his circle and take it to his charge superintendent. The latter was similarly to prepare a total for his charge, and send it to the District Officer, who added up the charge figures and reported the district total by telegraph. This work was so admirably done that the results for the whole of India were received complete on the 19th March —*i.e.*, within nine days of the census—and were issued in print next day with full details, not only for Provinces and Agencies, but also for districts and states and the principal towns. This constitutes a world's record. Not even in the smallest European States are the provisional totals published with the despatch attained in India. The accuracy of the figures thus obtained is also noteworthy. The net difference in the whole of India between them and those arrived at after detailed tabulation was only ·04 per cent., and for nearly half of this a mistake in one district in Burma was responsible.

The returns for many districts, states, and even provinces came to hand much sooner. Within four days of the census the figures had already been reported for a population of 134 millions, while on the sixth day they had been ascertained for 238 millions, or nearly four-fifths of the whole. The record was broken by two Native States (Rampur and Sarangarh), where the census staff set to work to prepare the provisional totals the moment the final census had been completed, and, by dint of working all night, were able, with the aid of mounted messengers and other means of conveyance, to get the figures for all parts of the state to headquarters in time for the telegram reporting the result to reach Calcutta by 8 a.m. on the following morning. The provisional totals for the Kashmir State, with its sparse population and bad communications, were ready within four days of the census, although in some cases the local figures had to be carried for upwards of two hundred miles over snow-covered passes and across rivers swollen by the heavy rain which fell on the 10th March and following days. In one of the Himalayan districts of the United Provinces, where the difficulties were equally great, two forest peons carrying the figures from an outlying circle lost their lives in trying to cross a river in flood. The Bastar State has an area of 13,000 square miles, and a sparse and primitive population, who a few months previously had risen against their chief. It is 150 miles from any railway, and there are very few roads. The local results were brought in by relays of policemen posted every few miles, and the telegram announcing the total for the state reached Calcutta on the fourth day after the census. It may be noted, as a matter of curiosity, that in Balaghat a man-eating tiger, which was holding up all night traffic, was shot by the Deputy Commissioner just before the census, and the enumerators were thus enabled to go about their work unmolested.

The above are only a few instances illustrating the devotion to duty which animated all ranks of census officers, and which is all the more remarkable when it is remembered that very few of them received any payment for their services. Nor was it only the actual staff who vied with each other in making the census a success. Private owners of horses, camels, and even motor-cars, were most generous in lending them in order to facilitate the speedy transmission of the figures to district headquarters.

I venture to think that the above details are of interest, not merely as showing the efficiency of the census organisation, but also as proof of the public spirit and loyalty of the staff, and of the knowledge of the people, tact, energy, and administrative capacity of the District Officers, in Native States as well as in British territory, on whom fell the brunt of making and carrying through the local arrangements for the census.

Special Arrangements.

Amongst the peculiar difficulties of an Indian census may be mentioned the long lines of railway, the big rivers on which boats travel sometimes for days without coming to the bank, the forests to which wood-cutters resort, often for weeks at a time, and the numerous sacred places, which, on occasion, attract many thousands of pilgrims. It would be tedious to describe all the special arrangements which were made in these and similar cases; it must suffice to give a brief outline of the measures taken on the railways. All persons travelling by rail who took tickets after 7 p.m. on the night of the census were enumerated on the platform, if there was time, and, if not, in their train. Those alighting at any station during the night were enumerated there unless they could produce a pass showing that they had already been counted. All trains were stopped and every carriage visited about 6 a.m. on the following morning, in order to include any travellers who up till then had escaped notice. At one large junction alone sixty special enumerators were engaged for the census of travellers by rail.

Hosted by Google

The Tabulation of the Results.

In the matter of taking the census, there has been no material change of system since 1881. In connection with the tabulation of the results, however, a new departure was made in 1901, when the slip system, which was first used by Dr. Georg von Mayr at the Bavarian census of 1871, was substituted by the late Sir Herbert Risley for the old method of abstraction by ticks. Under this system a separate slip is prepared for each person, on which all the necessary particulars regarding him are noted. The slips used on the present occasion measured 4½ in. by 2 in.; religion was denoted by the colour of the slip, and sex and civil condition by symbols printed on it. The amount of writing required for the other entries was reduced by means of abbreviations; and one man was thus able, on the average, to prepare about five hundred slips a day. It may be interesting to note that these slips, placed end to end, would form a narrow band of sufficient length to encircle the world at the equator. After the slips had been prepared, they were compared with the original entries in the enumeration books, and the number of each sex was checked with the enumerator's abstract. If any difference was disclosed, the slips were again compared with the books. Those for each circle were then sorted by sex and religion, after which all the slips of the same sex and religion were thrown together for the tahsil or other unit, and sorted and re-sorted for the different tables. This method of work is not only much simpler and more expeditious than the one which it superseded, but it is also more accurate and can more easily be tested.

In 1901, the slip system being new to India, the local superintendents were allowed considerable latitude in the methods of applying it. At the present census, in the light of the experience then gained, a general code was prepared, on the basis of which provincial superintendents drew up their instructions, with such modifications as were necessary in view of local conditions.

The Information Collected and Compiled.

The information collected included, as usual, sex, age, religion, civil condition, caste or race, occupation (including subsidiary occupations and the means of subsistence of dependents), language, birthplace, education, and certain infirmities. Sect was recorded for Christians, and, in some provinces, for other religions also. In a few provinces the sub-caste was entered as well as the caste. A new feature was the use of a separate schedule for obtaining information regarding persons working in factories and other industrial undertakings in which not less than twenty hands were employed. Special returns were also obtained of persons working on railways and canals, and in the Postal and Telegraph Departments. In this way a good deal of information has been collected which cannot be got from the occupation columns of the ordinary census schedules.

Changes in the form of the final tables are to be deprecated, as they impede comparison with the results of previous enumerations. The only material alteration made on the present occasion was in the occupation tables. It had already been recognised that the Indian classification was too elaborate, and the opportunity was taken, while simplifying the scheme, to recast it in accordance with the one drawn up some years ago by M. Bertillon, and recommended for general adoption by the International Statistical Institute. In doing so, the more important detailed heads of the previous scheme were retained unaltered, so that it will still be possible to compare the main figures with those of 1901.

Population and Density.

The total population of India is now 315 millions, of whom three-fourths are resident in British territory and one-fourth in Native States. The mean density of the population is 175 per square mile, but there are great local variations; from 900 and upwards in a few favoured districts of Bengal, to less than fifty in Burma, Kashmir, the west of Rajputana, and Baluchistan. In the last-mentioned province, including its states, there are only six persons to the square mile. Apart from past political conditions, the rainfall is the main factor in determining these variations, but the configuration of the surface and the nature of the soil are also of importance. The density is greatest in the Gangetic plain, where the rainfall is ordinarily ample and the soil is a level alluvium, practically every inch of which is cultivable except where it is covered with water. The next most thickly inhabited tracts are two narrow strips along the coast on each side of the peninsula. Gujarat, though it has been called the "garden of India," supports barely a quarter of the number of persons per square mile found in the delta of Bengal. Its rainfall is more scanty and less regular than that of Bengal, the surface is somewhat undulating, and the soil more sandy. The low density in

Hosted by Google

Burma is due to historical reasons; with the advent of a settled government the population is rapidly increasing. In the elevated tract in the centre of the peninsula, not only is the rainfall comparatively light and uncertain, but the surface is broken and irregular, and the soil is often thin and stony. In western Rajputana, Sind, the south-west of the Punjab, and Baluchistan, the rainfall is so scanty that very little cultivation is possible without the aid of irrigation. That the soil itself is fertile enough is shown by the large yield of wheat in the canal colonies of the Punjab.

There is at present no general correlation between irrigation and density of population. In the tracts where the density is greatest the rainfall in ordinary years is ample, and there is no need for an artificial supply of water. Where, on the other hand, the rainfall is scanty or very precarious, the population has hitherto been sparse, and the canals which have been constructed have not yet had time to produce their full effect. It may be mentioned in passing that the construction of irrigation works has often been accompanied by a deterioration in the public health, due to the spread of malaria. The question of malaria prevention is one of India's most urgent problems; and it is earnestly to be hoped that success may attend the efforts which are now being made to cope with it.

Growth of Population.

The population has grown by 53 per cent. since 1872. Part of this increase, however, is due to the inclusion of new areas, and part to the greater accuracy of recent enumerations. The following statement shows, as far as can now be ascertained, how far it is attributable to these causes and what the actual growth of the population is believed to have been:—

Period.	Increase due to — Inclusion of new areas.	Increase due to — Improvement of method.	Real increase of population.	Total.	Rate per cent. of real increase.
	Millions.	Millions.	Millions.	Millions.	
1872–1881	33	12	3	48	1·5
1881–1891	5·5	3·5	25	34	9·8
1891–1901	2·5	·2	4·3	7	1·5
1901–1911	1·5	...	19	20·5	6·4
Total	42·5	15·7	51·3	109·5	19·3

Note.—The total percentage of real increase has been calculated on the assumption that the rate of increase has been the same in the "new" areas as in the old.

The fluctuations from one decade to another reflect the intimate connection which exists in an agricultural country between the harvests and the growth of the population. In the first of the above periods a series of bad seasons, culminating in the great famine of 1876–78, kept the population almost stationary. The next decade was one of general agricultural prosperity, and the increment was large in consequence. Between 1891 and 1901 there were two widespread and disastrous famines, which not only caused a heavy fall in the birth-rate, but also, with the diseases which followed in their train, led to a mortality, chiefly in the Native States, of about five millions in excess of the normal. The ensuing ten years, though marked by a few local famines, were, on the whole, favourable to agriculture, and the result has been an accelerated growth of population. The increase would have been far greater but for the extremely unfavourable state of the public health in Upper India. Malarial fevers were terribly prevalent in the irrigated tracts of the eastern and central Punjab, and in the Ganges-Jumna Doab in the United Provinces. Plague also caused great havoc in these provinces and Bombay, and in parts of Bihar and the Central Provinces; the total recorded mortality from it during the decade in British territory was six and a half millions. These diseases caused a decline in the population of the Punjab and United Provinces of about half a million in each case, when otherwise—at least, in the Punjab—a large increase might have been looked for.*

The variations which have occurred during the last ten years in individual provinces and states are shown in Table B. It will be seen that while, taken as a whole, British territory has an increase of 5·5 per cent., the Native States have gained 13 per cent. Some of these states had lost heavily in the famines of the previous decade, when they showed a net decrease of 5 per cent., compared with an increase of 4·7 per cent. in British territory, and many of them are still so sparsely populated that there is much more room for growth than there is in most British provinces. Taking the district or state as the unit, it may be noted that 332 units, with a population in 1901 of 223 millions, have gained 11 per cent., while 86, with a population of 71 millions, have lost 5·3 per cent.

It has sometimes been assumed that the increase during the ten years ending in 1891

* It will be shown further on that the excess mortality occurred chiefly amongst women. The result will be a diminished birth-rate in the immediate future.

Hosted by Google

represents the normal rate of growth in India, or the rate which might always be expected to obtain were it not for famine and other similar calamities. That decade, however, like the one which has just come to a close, followed on a period of famine, with a retarded birth-rate and a heavy death-rate. The excess mortality in the famine years had occurred mainly amongst the very old and the very young: persons in the prime of life—*i.e.*, at the child-bearing ages—were but little affected. The conditions were thus favourable to an abnormally rapid growth of population. With restored fecundity and an undiminished number of persons at the child-bearing ages, the number of births would be greater than usual. On the other hand, there would be far fewer deaths, since so many of the "bad lives," which would otherwise have swollen the mortality, had already disappeared. This rebound after famine is always very marked. In Madras the famine of 1876–78 caused a slight setback at the ensuing census. This was followed ten years later by an increase of 15·6 per cent. The rate of growth fell to 7·3 per cent. in 1901, and it has now risen to 8·3 per cent. The comparatively small figure for the decade 1891–1901 was probably an aftermath of the famine, the new generation of potential parents being smaller than it would otherwise have been. The Central Provinces and Berar afford another instance of rapid recovery from famine losses. Owing to the famines of 1897 and 1900, the population in 1901 showed a decrease of 8 per cent. In the last Census Report for India, I pointed out that this loss had occurred entirely at the two extremes of life, and predicted that, in the absence of any fresh calamity, it would be made good before many years had elapsed. This forecast has proved correct. The increase during the ensuing decade was no less than 16 per cent.

The growth of population depends not only on the prevailing sanitary and material conditions, but also on the sex proportions and on the age constitution, which is constantly changing. There is no such thing as a normal rate of increase. All that can be said is that since 1872 the average increment has been about 5 per cent. per decade. If the population were to continue to grow at the same rate, it would double itself in about a century and a half. Compared with the Teutonic races, this rate of increase is very moderate, but it is greater than that of the Latin nations. The birth-rate in India is high, but so also is the death-rate. The mortality amongst children is particularly heavy, especially during the first year of life, when it sometimes exceeds one-third of the number born. With the advance of sanitary science, this mortality will no doubt be reduced, but even so, a greatly accelerated growth of the population cannot be expected so long as it continues to be so largely dependent on agriculture.

It is difficult to form any estimate of the additional agricultural population which India is capable of supporting with the present methods of cultivation. There are extensive areas where there is still scope for expansion, especially where irrigation can be carried out on a large scale. The largest and most successful of the completed irrigation schemes is the one by which several thousand square miles of waste land in the Rechna Doab have been converted by the lower Chenab canal into a most prosperous wheat-growing tract. It was previously inhabited only by a few pastoral nomads, numbering in 1891 at the most 70,000; but as soon as the canal began to be effective, immigrants flocked in. By 1901 the population had already risen to 792,000, and ten years later to 1,071,000. It has been estimated that it will ultimately reach two and a half millions. On the other hand, there are tracts—chiefly in the United Provinces and Bihar—where there seems to be scarcely any room for further growth. Mere density, however, is not always a safe criterion. Some of the most thickly-peopled districts of East Bengal are still growing very rapidly. Dacca, with 952 persons to the square mile in 1901, has added 11 per cent. to its population, and Tippera, with 848, nearly 15 per cent. The people of these two districts are extremely prosperous, and there is no reason to suppose that the limit of expansion has been reached.

The Urban Population.

There is nothing new to say regarding the general distribution of the urban population. In India, as a whole, only about one-tenth of the inhabitants live in towns. The proportion is lowest in the north-east and extreme north-west of India, and highest on the west coast. Contrary to experience in Europe, where the domestic servants are mostly women, the proportion of females to males is usually less in urban than it is in rural areas. As might be anticipated from their occupations, an exceptionally large proportion of the Parsi and Jain communities reside in towns. According to the census, the urban population has grown since 1901 by ·3, and the rural by 7·8 per cent. The figures, however, are vitiated by the fact that at the time of the census plague was raging in many towns, chiefly

in the United Provinces, the Central Provinces, and Central India, and large numbers of the regular inhabitants had gone away. A fresh count taken a few months later often gave far larger figures than those of the general census—*e.g.*, in Nagpur, where the difference was no less than 33 per cent. Calcutta, with its suburbs and Howrah, now has a population of nearly a million and a quarter. The increase during the decade is 10 per cent., or less than half that during the previous ten years. In Calcutta proper the increase is less than 6 per cent., but in the suburbs of Maniktola and Garden Reach it is nearly twelve times as great. Owing to the removal of slums and improvements in the means of locomotion, the tendency is growing for workers in the city to make their home in the suburbs or even further afield; a similar tendency has been noticed in some other towns also. Bombay, with nearly a million inhabitants, shows an increase of 26 per cent., but it must be remembered that in 1901, owing to a severe visitation of plague, the population was abnormally small, being, in fact, slightly less than it had been ten years previously. The population of Madras is almost stationary. Hyderabad, the capital of the Nizam's dominions, has a gain of 12 against 8 per cent. in the previous decade, and Rangoon of 19 against 35. The largest proportional increase amongst cities, or places with not less than 100,000 inhabitants, is shown by Karachi, which has grown by 30 per cent. Dacca has added 21 per cent. to its population. Owing to plague, all the cities in the United Provinces show an apparent decline, but in the Punjab, Delhi and Lahore have increases of about 12 per cent. in spite of a falling off in the adjoining rural areas.

The Sex Proportions.

In most parts of Europe the females outnumber the males. More boys than girls are born, but the mortality amongst them is greater both in infancy, owing to physiological reasons, and in later life owing to the greater risks to which they are exposed in their daily avocations. In India, as in most other parts of the world, males are in excess. The proportion of the sexes at birth is not very different from that in Europe, but subsequent conditions are relatively less favourable to female life. Female children are not wanted, and it is well known that the practice of killing them was formerly widespread amongst certain communities, chiefly in the north-west of India. A striking instance of this came to the notice of a friend of mine a few years ago. He was discussing with the Durbar of a Native State the amount which ought to be expended on the marriage of the Chief's sister, and, as there was some difference of opinion, he asked how much had been spent on similar occasions in the past. He was told in reply that *there was no precedent*. This girl was the first in the family who had been allowed to live! A middle-aged Punjabi gentleman recently told me that he had been compelled, as a boy, to assist at the murder of his infant sister, and that an aunt had had seven daughters and killed them all. He was careful to add that his family has since abandoned such practices. But even now there is much neglect of female children. Girls are neither so well fed nor so well clothed as boys, nor, if ill, are they so carefully looked after. In Gujarat there is a proverb that "the parents look after the boys, and God looks after the girls." Early marriage and child-bearing, coupled with all the risks attendant on unskilful midwifery, are also responsible for many deaths. Speaking of the results of early marriage, the Census Superintendent of a Native State in 1901 wrote as follows:—

"Numbers of these girls march from the nuptial bed to the funeral pile. Nervous debility, consumption, and uterine diseases create a havoc among them."

These adverse conditions affecting female life would seem to be sufficient to account for the difference in the proportions as compared with Europe, but it has sometimes been attributed in part at least, to the relatively incomplete enumeration of females owing to the seclusion in which they are kept. It may be pointed out, however, that if reticence regarding females were the cause of the difference in the proportions, it would be greatest in the case of Muhammadans, but in almost every part of India the proportion of females amongst Muhammadans is greater than it is in the same locality amongst Hindus. Concurrently with the greater accuracy of each succeeding census from 1881 to 1901 there was a steady rise in the proportion of females, and it was assumed by some that there was a connection between the two phenomena. That this was not so is shown by the fact that the proportion of females has now fallen to what it was in 1881. The variations which occur from time to time depend partly on changes in the proportions at birth which, whatever their cause, are known to occur, and partly on changes in the relative mortality of the two sexes. It has been clearly established that in severe famines the mortality amongst women is less than it is amongst men. This is due to their being less

Hosted by Google

metabolic, and to the fact that it is chiefly women who get gratuitous relief, do the cooking, handle the food supply for their children, and collect the jungle products, with which they eke out their ordinary food supplies. The rise in the proportion of females in 1901 was thus due, to a great extent, to the famines of 1897 and 1900. The diminution which has now taken place is the result of the greater mortality which has occurred amongst them from plague and malaria in Northern India. Being largely confined to their houses, women are more exposed than men to infection by plague-bearing rat-fleas and malaria-carrying mosquitoes.

It is impossible within the limits of this paper to discuss the local variations in the sex proportions in different parts of the Empire. I may mention, however, that the proportion of females is lowest in the north-west of India. This is the tract where female infanticide was formerly common, and it would take a generation for the discontinuance of this practice to have full effect on the proportions, even if there were no longer any serious neglect of female infant life. In this tract, moreover, there is a relatively high proportion of males at birth. Darwin has pointed out that this would naturally be the result of long-continued female infanticide, if it be assumed that there is a hereditary tendency to produce one sex more than the other. Girls would be killed chiefly in families where they are more numerous than boys, and spared where they are in a minority, and the survivors would thus be those with a male-producing tendency.

Religion.

The Hindus, though they form 69 per cent. of the total population, claim only half of its net increase during the decade. Owing mainly to their social customs, and especially the common prohibition of widow marriage, their natural rate of growth is relatively slow. It is difficult to draw the line between Hindus on the one side, and Jains, Sikhs, and Animists on the other. The tendency is growing for Jains to call themselves Hindus; but in the Punjab many persons returned as Hindus in 1901 have now been entered as Sikhs, and a similar change of procedure elsewhere has augmented the number of Animists. The net result has been some diminution in the number of persons recorded as Hindus. There have, besides, been losses by conversions to Christianity, and also, though to a less extent, to Muhammadanism. It may be interesting to mention that the members of the Arya Samaj are endeavouring to counteract this steady drain by taking back into caste those who are willing to return to the Brahmanical fold. But ordinary Hindus will not always accept their authority in a matter of this kind, and it is with them that the decision really rests. The Muhammadans, in spite of their greater prolificness, the reasons for which were explained in the last census report, and occasional gains from the ranks of other religions, have increased at slightly less than the average rate. This is because a quarter of their total strength is found in the two provinces which have sustained a loss of population. They have more than held their own in each province and state taken separately. The number of Christians is now nearly four millions—a gain of a million in ten years. The largest actual addition (411,000) has occurred in Madras and its Native States, which contains three-fifths of the total number of Christians in India, but the greatest proportional increase (200 per cent.) is in the Punjab. The figures for

District or State.	Number of Christians.	
	1911.	1901.
Ranchi	177,473	124,958
Jashpur	36,880	12
Gangpur	33,692	1,758

this province came as a surprise, even to some of the missionaries. Numerous conversions continue to be made amongst the aboriginal tribes of Chota Nagpur. The missions to the Khasis and other hill tribes of Assam, and to the Karens of Burma, are also highly successful. The value of the work done amongst these primitive races, moreover, must be measured not merely by the number of converts, but also by the good which the missionaries have done in other ways. It is they who have reduced the languages of these rude tribes to writing, and who have taken the lead in educating and civilising them.

Of the modern Hindu schismatics, the Brahmos have made very little progress, but the Aryas are nearly three times as numerous as they were ten years ago. They still number less than a quarter of a million, but they include in their ranks an exceptionally large proportion of educated persons.

Education.

The inquiry regarding education was limited, as in 1901, to the question whether each person was literate, and, it so, whether he could read

† Manipur figures were omitted in 1872 and 1891, but included in 1881, 1901, and 1911.

and write English. In 1901 no general indication was given as to the degree of proficiency in reading and writing which should qualify a person to be entered as literate, and the practice varied a good deal according to the view taken by the local officers. In Madras it was laid down that only those should be so entered who could write a letter to a friend and read his reply. This seemed as good a criterion as could be devised; and as uniformity is obviously desirable, it was this time prescribed for general adoption. Its application has in some parts led to the entry as illiterate of persons who would otherwise have been shown as literate; but in spite of this the proportion to the total population returned as able to read and write has risen during the decade from ninety-eight males and seven females per mille to 106 and 11 respectively. The progress amongst males has been greatest in Eastern Bengal and Assam, Madras and Mysore, and amongst females in Baroda and the United Provinces. The proportion of literate persons is greatest in Burma and the extreme south of India, and smallest in the north-west. The Dravidian and Mongolian elements in the population appear to be more alive to the advantages of education than the Aryan.

In India, as a whole, ninety-five males and ten females per ten thousand are literate in English. Amongst the main British Provinces Bombay leads, and the United Provinces come last. A colloquial knowledge of English is probably most widespread in Madras, but the English-speaking servant or coolie was not ordinarily returned as literate in that language.

Infirmities.

Information is collected at the census regarding four infirmities—insanity, deaf-mutism, total blindness, and leprosy. Up to 1901 there was a progressive decline in the number of persons thus afflicted, owing mainly, in 1891, to better diagnosis, and in 1901 to the famines of the preceding decade. A very large proportion of these unfortunate persons are beggars, and it is they who suffer most when scarcity occurs and the springs of private charity dry up. The last ten years have been fairly prosperous, with the result that the number of the afflicted has risen, though it is still less than it was twenty years ago. Of every 100,000 persons, 26 are insane, 64 deaf-mute, 142 blind, and 35 lepers. Blindness affects the two sexes almost equally; but the number of females returned as insane or deaf-mute is only about two-thirds that of the males, while in the case of lepers it is barely one-third. No one but a beggar will willingly say that he is a leper. This natural reticence is largely discounted in the case of males by the local knowledge of the enumerators, but there can be no doubt that many female lepers must have escaped entry as such. The figures, however, can be relied on for comparative purposes. The proportion of lepers, as compared with the abnormally low one of 1901, shows a smaller increase than do the other infirmities, and it is still much below that of 1891. It may thus, perhaps, be inferred that the disease is showing a tendency to disappear. If the latest theory that the bed-bug is the common medium of infection be correct, a decrease would naturally result from the more frequent segregation of lepers in asylums, and the steady improvement which is taking place in the material condition of the people.

DISCUSSION.

The Chairman, in opening the discussion, said the paper made one very anxious to receive the full report of the census, but from what they had heard that afternoon it appeared that the mere enumeration had been an admirable piece of administration. He also thought the great amount of public spirit shown in India by the extent and value of the voluntary services for the census should be put on record. He had been very interested to see that Mr. Gait had spoken so definitely upon the causes of that rebound of population after famine to which their attention had been called. For some time there had been a theory that the privations through which the people had passed caused an increased fecundity, and that it was an example of the *vis medicatrix naturæ* which caused the spontaneous increase of population to follow upon hardships. That rather attractive theory seemed to be corroborated by evidence of some breeders of animals. Mr. Gait, however, found other and, as appeared to him (Sir Theodore), more substantial reasons. One was that the child-bearing population was the one which survived best during famine, and that the loss of life took place at the two extremes—amongst children and the very old—so that the child-producing capacity of the population was not thereby impaired. He wondered whether some of the previous Commissioners of the Census were satisfied that some fair estimate of the rate of increase of the Indian population had now been arrived at. If Mr. Gait had placed before them reasonably reliable data for forming a calculation, it would seem that the estimates of population at the beginning of the nineteenth century—which of course were very rough—appeared to have understated the population at the time. It was said that the population at the beginning of the nineteenth century was probably 100 to 150 millions, and on the basis

Hosted by Google

of that calculation some rather exaggerated estimates were made of the rate at which the population must have increased before the first regular census was taken. It seemed to him, speaking without any expert authority, that Mr. Gait's calculation would bring the population at the beginning of the nineteenth century more nearly to 200 millions. The sex proportions of the population had struck him as extraordinarily puzzling when the first results were brought out. There seemed to him to be no rhyme or reason in the large preponderance of males in some provinces, and the curious equality of sexes, especially towards the east of India in the two Bengals. He hoped that point would be dealt with at greater length in the full census report.

Sir William Chichele Plowden, K.C.S.I. said the paper teemed with interest from the commencement, where it dealt with the valorous bravery of the forest peons who lost their lives in their endeavours to do their duty, to the very end of it, where Mr. Gait dealt with that pestilence that "walketh in darkness," known as the bed-bug. Three points had struck him in reading the paper, firstly, the great rapidity with which the work of the census had been performed; secondly, the extraordinary increase of the Christian population; and lastly, and what was very remarkable, the increase of the literate population, especially among the women. In passing, he might mention that a table appended to the paper showed that part of the increase in the population was due to the inclusion of new areas. He hoped that a censorious public would not understand from that that Great Britain through its administration had been grabbing territory. Those new areas were not new areas by conquest, but simply old areas in which the former enumerations did not exist. He supposed there was no census in the world which had disclosed its results so quickly as Mr. Gait's census, and it certainly was essential to India to have the most rapid knowledge of the increase of its population. The extraordinary increase in the Christian population was very largely confined to aboriginal districts, especially the three districts belonging to Chota Nagpur. He had been talking to a missionary friend, who had informed him that the Bible was having a very great influence in the country. Turning to the extraordinary increase in the literate character of the population, the increase in the female literate world was remarkable when compared with the increase in the male literate world. The increase in the case of females was 50 per cent., compared with a 10 per cent. increase in the case of males. The influence that the acquisition of knowledge on the female side of the household in India would have upon the welfare of the country was something upon which Indian officials might very well dwell with great satisfaction. The changes in the country were vast and extraordinary. To him, who had been away from India thirty years, he was sure there were things occurring which would be perfectly novel, but they were occurring in the right direction, and he thought India could look forward in the future to a happier state of things than it had ever enjoyed in the past.

Sir Athelstane Baines, C.S I., mentioned that it was under his auspices that Mr. Gait first began census work, and he heartily congratulated that gentleman on the great success with which he had accomplished one of the most difficult tasks in census-taking in the world. Mr. Gait was first brought before his notice by the Chief Commissioner of Assam as a capable district officer, and, therefore, he possessed just the qualifications required for arranging the census preliminaries. Mr. Gait then developed a remarkable taste for statistics, and had acquired a knowledge of scientific works, both in French, German and English, bearing on census work, which had been unrivalled in his (Sir Athelstane's) time in India, and, which he believed was unrivalled at the present day. The work he did in 1901 gave him (Sir Athelstane) full confidence in saying that the census report of 1911 would be far superior to all previous reports. Mr. Gait also had another qualification which was very useful in India. Everyone who took up census work there developed, whether voluntarily or involuntarily, a taste for ethnography. The figures regarding castes and religions that came before one were so replete with interest that even those who began with no taste whatever for the subject were bound to go into it. The only danger was that one might overstep the bounds of ethnography—which came legitimately within the scope of the census—and trespass on the domain of ethnology, which was a very different subject. Mr. Gait had been made Surveyor of Ethnography after the first census, and he had continued his work in that direction ever since, and would carry on the task so splendidly begun by the late Sir Herbert Risley. In the taking of a census, India had one or two great advantages over this country. In the first place there was in India an efficient co-ordination of the official hierarchy. India was exceedingly fortunate in having a more or less permanent agency, or the cadre of an agency, which it could supplement at the time of the census either from official sources or from outside. A second great advantage which India possessed was the comparative immobility of its population. The census of India could not possibly be taken in one night unless what was called the preliminary record was prepared. A record of all the habitual residents in a village or town, or street, or whatever might be the unit of enumeration, was made at varying times from a month to ten days before the census, and on the night of the census that record was brought up to date. Without such a system it would be impossible that 315 million people could be enumerated, even with the assistance of the two million enumerators whom Mr. Gait had

Hosted by Google

under his control; it would require fifteen, or even twenty million enumerators to enumerate that number properly *de novo* on the night of the census. The preliminary record was only possible because not more than 5 per cent. of the people would move anywhere out of their habitual residences in the month before the census—and that figure represented the amount of correction necessary to bring the record up to date. A third great advantage which India had over this country in the matter of taking the census, was the number of volunteers. Almost every well-educated person was at the disposal of the local officer, and the tribute which had been paid to them had been well earned. Passing to the results of the census, the figures which had been produced in such an extraordinarily short time were those necessary for immediate and direct administrative purposes. He understood, however, from Mr. Gait that the more elaborate tables were complete, though of course he was not at liberty to publish them until they had been embodied in the report. That was quite a right procedure to follow, because it would be very misleading to publish merely a set of figures in a series of tables. They had to be subjected to very serious examination, and it must be shown where the figures were comparable and where they were not susceptible of comparison with each other or with the figures of other countries. He had seen comparisons instituted between figures for India and figures for some Western countries which were insusceptible of comparison. One of the results of the census, which was of marked importance, was the rate of increase of the population. The rate for ten years in almost every old or settled country ranged from 6 to 8 or 9 per cent. at the most, and he was of the opinion that a moderate rate like 6 per cent. was all that India was likely to get, and all that India was likely to be able to support. Considering that ninety-nine out of every hundred natives of India obtained their subsistence from the cultivation of the soil, a decennial increase of nineteen or twenty millions was as much as India could stand. The question of the density of population must be taken in consideration with the question of occupation. The figure of 175 per square mile given in the paper was a mere arithmetical expression, and was worth nothing statistically. It was not typical of more than a very small area of the country. In India, with its great variety of circumstances between different parts of the country, it was not numerical density that had to be taken into account, but economical density. Mr. Gait had mentioned the possibility of increasing the density per acre by irrigation, but where that was not resorted to, districts with less than 150 per square mile might be economically as congested as districts with three times that population in the more fortunate parts of the country. Referring to the Chairman's question about earlier populations, if he (Sir Athelstane) might be allowed to say so, every surmise and every estimate made about the population before 1840 was not worth printing.

Mr. Bernard Mallet, C.B. (Registrar-General), said, as being responsible for the conduct of the last census of England and Wales, he desired to congratulate Mr. Gait on the splendid success of his vast undertaking. He agreed with Sir Athelstane Baines that India possessed a good many advantages over this country in taking a census, the chief advantage being the command it had over the great administrative machinery. All he (Mr. Mallet) had to call upon was his very small expert staff in his office and two or three thousand registrars and superintendent registrars of births and deaths in the country and any local official he could obtain by going cap in hand to the local authorities. To create organisation under those circumstances was not a very easy matter. Then again apparently India did not have to pay anybody. In this country about two-thirds of the expense of the census was caused by payment to local officers, only one-third being caused by the cost of tabulation. The cost of the 1901 census worked out at about 11*s*. per head in India and about £5 per head in England. He had been attracted by Mr. Gait's remarks as to the superiority of the work done by paid enumerators in India as compared with individual householders in filling up the forms. He thought that remark would probably be true even of a country of comparatively educated people like ourselves. The census officials in this country during the last census had gone as far as they possibly could in the matter of adding questions to the schedule, and they only succeeded by careful process of education through the elementary schools, trades' unions, and the Press in teaching the public how to answer the questions. Some questions—for instance, that about infirmities—really could not be filled up by the public. He himself had been rather anxious to leave out the whole column about infirmities, but the authorities thought otherwise. The figures, however, obtained in that connection were of no use whatever. He was of the opinion that in an ideal system the schedule should be filled up mainly by the enumerators. The idea of having a preliminary record made before the census day by enumerators seemed to be an extremely good one, and he wished such a system could be copied in this country. He was afraid the question of expense would prohibit the idea of following the Indian example in these matters. He had often wondered whether it would be possible by making a great appeal to the public spirit of the country to get people to volunteer to do the work, but he supposed it would not be, after all the past years of paid enumerators. He did not see any other way of improving the usefulness of the census unless the public were willing to pay a good deal more than they did at the present time. One point which had interested him was the adoption of the international scheme of classification. He should much like to know to what extent the list of occupations, drawn chiefly from the French, German and English sources, was adapted to the

Hosted by Google

more primitive conditions of India. The classification of occupations in India must be simpler, easier and more satisfactory than in this country, where the sub-divisions of industry were so great as to make it almost impossible to secure an ideal system by which the personal occupation of people in different countries could be compared. The census officials in one respect had followed the excellent example of India in introducing a system of slips or cards, which were tabulated here by machinery. He supposed it was not necessary to use mechanical means in that respect in India on account of labour being so cheap. He could add many instances of errors to those given by Mr. Gait. He certainly had every sympathy with the High Court Judge mentioned in the paper, and indeed, he had to confess, in filling up his own schedule he made a mistake, but luckily he corrected it before it came under official cognisance. One old lady of eighty-six had described her occupation in the words: "Proverbs, chapter xxxi. verse 27." On being looked up, the words were found to be: "She looketh well to the ways of her household and eateth not the bread of idleness."

Sir Thomas Holdich, K.C.M.G., K.C.I.E., proposed a hearty vote of thanks to the author, and on behalf of the Committee thanked Sir Theodore Morison for presiding, and Mr. Anderson for reading the paper. He thought very few people understood what enormous problems vital to the interests of the nation were wrapped up in the pages of a census. For instance, Major Darwin, the President of the Eugenics Society, had recently pointed out the difference in the increase of the undesirable population in this country as compared with that of the desirable or tax-paying classes, from which he argued the decadence of the British nationality. Only when the completed census of India was available would the difference in the percentage of increase between the desirable and the undesirable classes of India be observed.

Sir James Wilson, K.C.S.I., in seconding the resolution, mentioned that he took the census of a district of 250,000 inhabitants in India in 1881, and in 1891 he took the census in another district of 500,000 inhabitants, and it was, therefore, very interesting to him to have all the various incidents which attached to the taking of a census recalled by the paper. He himself was within measurable distance of being a Census Commissioner. In 1901 he had been told that his name had been sent up to the Government of India for that post, but the Government had very wisely appointed Sir Herbert Risley instead. He had received an inkling that afternoon why he had not been selected, as Sir Athelstane Baines had said that for the post of Census Commissioner a man was wanted who did not know anything about mathematics; and perhaps it had been discovered that he had once had some slight knowledge of that subject. He thought all must be impressed by the rapidity with which the last Indian census had been taken. It was a triumph of organisation, and showed what an enormous and far-reaching influence and power the Government in India had when it could enlist the voluntary work of so many people throughout the whole country. That same voluntary effort was available to the Government in India for other things besides taking a census, for instance, in combating famine. It would have been impossible for the Government to have saved the people from starving had it not been for that voluntary aid which had come to its assistance. He hoped to see that help used against the greatest enemy which India appeared to have—not famine, not plague, but malaria—and he trusted the Government would organise such a great campaign against that dread disease that practically the whole of the population would be persuaded to take part in it. There was one very important consideration to which he would like to refer. India had at the present time 315 million inhabitants. That number was increasing rapidly, and how would India support its population one hundred years hence? As far as could be seen the population was likely in time to overtake the means of production, and unless the birth-rate decreased there was a great danger of the general deterioration of the people. That was a question for the future, but it was one which those who were responsible for the government of India should always keep in view.

Mr. J. D. Anderson said he was sure Mr. Gait would wish his mouthpiece not merely to thank his audience for their obvious appreciation of his admirable paper, but also to express his gratitude to the experts, his distinguished predecessors in census work in India, and the Registrar-General, who had commented on what they had just heard. Perhaps, as Sir James Wilson had set the example of indulging in some natural reminiscences of census experiences in India, he (the speaker) might be allowed to add that Mr. Gait's reason for asking him to read his paper was perhaps the fact that, when he was Census Commissioner for Assam in 1891, he (Mr. Anderson) was one of the district officers who supplied him with figures. They once or twice indulged, as brother officers will, in friendly controversy as to details of enumeration, controversy in which the speaker was invariably worsted, and had an opportunity of admiring the powers of organisation which even then distinguished Mr. Gait as an administrator who was bound to make his mark. It was with a mind full of those now ancient controversies that he read his old friend's paper, and it had been a matter of much pride and pleasure to him to be his interpreter. He was glad to think that the interest and importance of this brief account of his great enumeration had been fully appreciated.

The vote of thanks was carried and the meeting terminated.

SIXTEENTH ORDINARY MEETING.

Wednesday, March 27th, 1912; LORD SANDERSON, G.C.B., K.C.M.G., Chairman of the Council of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Brandon, James Augustine, Battery House, Nepean Sea Road, Bombay, India.

Davidson, Alexander Rae, 150, Stradbrooke-place, Winnipeg, Canada.

Goodenough, Francis William, 1, Young-street, Kensington-square, W.

Groundwater, William, The Rising Sun Petroleum Company, Yokohama, Japan.

Maclachlan, Thomas, Mount Lavinia, near Colombo, Ceylon.

Payne, Harold William, Box 210, Durban, Natal, South Africa.

The following candidates were balloted for and duly elected members of the Society:—

Ba, Maung, Additional Magistrate and Small Cause Judge, Mandalay, Upper Burma.

Brunton, John Robert, 305, Padiham-road, Burnley, Lancashire.

Dass, Bahadur Luchman, c/o B. N. Rutton, Oliver Commercial School, The Mall, Lahore, India.

Finot, Leo, F.R.P.S., 27, New Bond-street, W.

Lichtenstein, Meyer, J.P., Pretoria Club, Pretoria, Transvaal, South Africa.

Okura, Kihachiro, Aoicho Akasaka-ku, Tokyo, Japan.

Sprott, Ernest M., 123, Victoria-street, S.W.

Ward-Thompson, B., Wilpshire, near Blackburn.

Young, Simon J., M.D., Main and Franklin-streets, Valparaiso, Indiana, U.S.A.

The paper read was—

THE WHALING INDUSTRY OF TO-DAY.

By THEODORE E. SALVESEN.

Whaling has been carried on since very early times, but it is only during the last three or four years that the industry, conducted on modern lines, has developed so enormously. I shall endeavour this evening to give as briefly as possible an account of its present position, showing the geographical distribution of the various whaling stations, the methods by which the whales are caught and their products reduced, the various species of whales hunted, and the commercial results of last season's operations in both northern and southern hemispheres.

DISTRIBUTION.

The pursuit of the Greenland Right Whale is now almost neglected, owing to the small catch caused by the scarcity of this species of whale, the most valuable of all the different kinds.

In the eighteenth century no less than 700 vessels, manned by 35,000 men, found employment in hunting the Greenland Right Whale from Spitzbergen to the Davis Straits and Baffin Bay. Now this industry in these waters is conducted by only five barque-rigged wooden auxiliary ice-protected vessels, of from 350 to 450 gross tons. The result of the last few years' operations has been anything but encouraging, and it is not unlikely that the number of this class of whalers will be still further reduced during the coming season, if indeed the industry does not cease altogether.

The Norwegian Sea, lying between the Faroes, Iceland, Jan Mayen and Norway, is annually invaded by about forty-five or fifty vessels, mostly sailers, in pursuit of the Bottle-nosed Whale. The result of last year's catch gave only about 900 tons of oil, which at the present ruling prices will not encourage any expansion of this special industry, which has been a declining one for several years.

In 1866 a whale was first killed by a method quite distinct and different from any known at that time—a method which will be fully described later on. The success attending the new method led to the formation of a great number of Norwegian whaling companies on the north coast of Norway, in the Finmarken district, as many as thirty-four steam whalers being employed in 1885 with a catch of about 1,000 whales. This industry came to an end in 1905, the prosecution of the whaling industry in the north of Norway having been prohibited by law at that time.

In Iceland the whaling was started about thirty years ago, and the industry is now carried on by two companies operating on the north-west coast with eight steam whalers, and by four companies on the east coast employing nineteen whalers. The results of the operations off the coast of Iceland have been unsatisfactory during the last few years, and consequently the industry will be conducted with fewer craft in the coming season.

At Spitzbergen there are two companies working, one with two whalers and the other with four. The season is a very short one, owing to the ice conditions, and the extension of whaling operations here is not looked for.

Off the Faroe Islands whaling has been

Hosted by Google

carried on for many years with varying success. Last year there were six companies operating with fifteen steam whalers, but this number will be decreased in the coming season.

Whaling off Shetland was commenced in 1903, and off the Hebrides in 1904. There are in all five companies interested, operating eleven steam whalers.

In 1909 the coast off the west of Ireland was invaded, with such satisfactory results that two whaling stations have been erected with licences to employ five whaling vessels. The experiences, however, of the last two seasons have been so unsatisfactory that no further development of these whaling grounds can be looked for.

Crossing the Atlantic to the Newfoundland coast we find only five whalers operating—all that is left of a large fleet which, started in 1899, flourished for only a few years, and gradually ceased to be anything but a negligible quantity over five years ago, when most of the whalers were sold to the Japanese.

The St. Lawrence River whaling was revived last year by a Norwegian-Canadian company, but the results of the first year's operations have not been satisfactory.

A specially constructed steam whaler was sent into the Davis Straits last season with orders to pursue the Right Whale and also the Finner species. Only twenty-four Finner Whales were captured, a result which will probably not lead to a continuance of this experiment.

I have now enumerated all the whaling operations carried on at the present time in the North Atlantic and Arctic Seas.

In the North Pacific there are still a number of barque-rigged, ice-protected wooden whalers which belong to San Francisco, and which pursue the Right Whale in the Behring Sea and neighbourhood. New Bedford seems also to have about twenty-seven of the old-fashioned vessels still surviving, but these, I understand, are principally employed south of the Equator hunting the Southern Right Whale and the Cachalot.

In 1840 we read that no less than 827 vessels were engaged in this industry, which number was reduced to about 160 in 1875, and since then has constantly been on the decline.

Off the coast of British Columbia the industry is being carried on with great vigour by ten modern whalers, which number during the coming season may be increased. The seas off these shores have proved themselves to be well stocked with the Finner variety of whales, and the business has been of so lucrative a nature that two or three new companies have been formed to commence during the next season, and to operate on a large scale, off the coast and islands of Alaska. These companies will fly the flag of the United States, whereby the products will be admitted to that country on preferential terms.

Before leaving the northern hemisphere, I have still to mention the Japanese whaling industry carried on under such protective conditions that all the crews, except some of the gunners, are Japanese, and the capital employed is wholly Japanese, the industry at present being conducted from twelve shore stations operating twenty-eight modern steam whalers. Little oil is exported, as the greater part of the carcasses is used for human food in Japan and the adjacent Korea.

A Norwegian enterprise, under the Russian flag, made experimental cruises from Vladivostok last season, fishing in the Sea of Okhotsk, and in the Behring Sea, but the results have not been satisfactory, only six whales having been secured.

This brings me to the end of the whaling enterprises in the northern hemisphere. It will be noticed that the industry is on the decline, except so far as the North Pacific Ocean is concerned, where there seem to be probabilities of favourable expansion.

The great increase in the whaling industry has come from the southern hemisphere, and I shall start from the Island of South Georgia, where it was first initiated about eight years ago. The whaling grounds of this small island in the South Atlantic have so far shown themselves to be the most lucrative ever discovered. At present there are in operation eight companies, working twenty-one whaling steamers. At the South Shetlands and Graham Land ten licences have been granted by the British Government for thirty steam whalers. In the Falkland Islands a British company operates five whalers. In the south of Chili in the Magellan Straits, one company has its station and factory, and two others are situated on the west coast of Chili. Another company has been formed to operate at Corral, and during the off season there the business will be carried on from the Galapagos Islands. The Kerguelen Whaling Company has its seat on the island of the same name, but its efforts so far have not been crowned with success in the whaling line, not owing to want of whales so much as to constant stormy weather conditions, during which it is impossible to carry on the hunt.

Hosted by Google

The whaling season at these South Atlantic stations closes about the month of May, by which time most of the whales have proceeded northwards into the warmer waters, and they are found in large quantities on the coasts of the continents of South America, South Africa, Australia, and New Zealand.

African whaling was started about four years ago in Durban, and the success was so striking that a great many companies have since been formed to share in the industry. Taking the west coast of Africa first, we have companies operating at Lobita, three in Elephant Bay, one in Mossamedes (a Portuguese company), one in Port Alexander, and one in Tiger Bay, all in Portuguese West Africa. Coming further south, concessions have been granted for Walfisch Bay, and probably whaling will be commenced there during the coming season. Two companies work from Saldanha Bay, one from Mossel Bay, on the south coast, and three from Durban. One station has been built at Inhambane in the Mozambique Channel, and another company operates at Angoche, the two latter being in Portuguese East Africa. Altogether thirty whalers were employed off South Africa, but during the coming season this number will be greatly augmented.

On the east coast of South America, so far, the whaling grounds round Bahia have only been tapped, but as the experiment proved successful one or two more companies are being formed to work with the neighbourhood of Bahia as their base.

Australia and New Zealand have only been tried experimentally, but the prospects seem to be so favourable that already several large ventures have been started in order to exploit the possibilities of the waters round the Australian continent, Tasmania, New Zealand, and other islands.

Methods.

So much for the geographical distribution of whaling stations. Let us now consider the way in which the animals are taken. Until the year 1866, the method of killing whales was either by throwing by hand, or by shooting from a gun or cannon, a harpoon with or without a bomb, and attached to a line. This was performed from the bow of a rowing boat, and if the whale was not killed outright by the first harpoon, which hardly ever happened, more harpoons were buried in the whale's body, shot there from the first boat or from others belonging to the same vessel, until the animal eventually was killed. As has been stated, the only species of whales which were pursued and killed up till 1866 were the Right Whale and the Cachalot, the reason for this being that these whales, when dead, float. The Finner Whales, on the other hand, sink when they are killed, and as their weight is considerably greater than the buoyancy of a whaling boat, it is impossible to secure them by a line from a rowing boat, as if one were to hold on to the whale line the inevitable result would be that the boat would be hauled under the surface of the sea. The Finner species are also much more active than the Right Whale and Cachalot, and seldom remain long enough at the surface to permit a rowing boat to approach them.

A Norwegian, Svend Foyn, was the first to solve the difficulty of how to kill and secure the large Finner Whales, and the methods introduced by him are now, with considerable improvements, those in use at the present time in all the modern whaling steamers. The most approved type of such a vessel is from 100 ft. to 115 ft. long, with a breadth of from 18 ft. to 21 ft. 6 ins., decked all over, and cut away at the bow and stern in order to make the vessel answer her helm quickly (Fig. 1). The lines of the hull are designed for a speed of from eleven to twelve knots, and the engines are of 350 to 650 effective horse-power. She is fitted with a glycerine recoil cannon, with a bore of about $3\frac{1}{2}$ ins. in diameter, and about 45 ins. in length (Fig. 2). The cannon is fixed on a swivel in the bow, and when loaded with powder and harpoon is so delicately balanced that the gunner can raise, and lower, and turn it from side to side, without any apparent exertion. The harpoon is of finest Swedish steel, and is about 6 ft. in length with a weight of a little over 1 cwt. It has four prongs, which spring out at right angles to the harpoon when the line is tightened after the harpoon is lodged in the whale's body. On the top of the harpoon is screwed a cast-iron head or shell, of conical shape, about 14 ins. in length and weighing about 11 lbs. This shell is charged with gunpowder and a time fuse usually explodes it three seconds after the harpoon has left the cannon. A 4 in., $4\frac{1}{4}$ in., or $4\frac{1}{2}$ in. foregoer, sixty fathoms in length, and made of the finest Italian hemp procurable, is attached to the harpoon, and to the other end of the foregoer a 5 in., $5\frac{1}{4}$ in., or $5\frac{1}{2}$ in. whale line of 120 fathoms is spliced on. If required, additional lines may be attached. There is a double set of lines on each boat, one on the starboard side and one on the port side, and the lines are most carefully coiled down in suitable bins under deck. A

large double whaling winch is fixed abaft the mast, with engines having cylinders of from 6 ins. to 7 ins. in diameter. Along the keelson from forward to the boiler bulkhead, are arranged double rows of steel springs connected to two snatch-blocks above the shrouds of the foremast by strong flexible steel-wire rope.

The whale is usually sighted by a look-out in the crow's nest on the mast. The steamer is then sent off in the direction of the spot where the whale was seen, but long before this is reached the whale has sounded, and the whaler moves towards the vicinity where it is expected that the animal will rise to breathe.

Gradually the distance separating the hunter from the hunted is lessened until the gunner gets within range, which is anything from about fifteen to twenty yards. The chase may go on for hours, and it often happens that the whale entirely disappears from sight and gives no chance at all for a shot. If the whale is killed outright the animal sinks, drawing with it the whale line paid over the drums of the winch. The steamer is brought to a standstill, and when the line hangs vertically it is stoppered in the bow, and the inboard part is passed into one of the snatch-blocks at the shrouds, and then round the drums of the winch, by which the whale is raised to the surface.

The object of the steel springs arranged in the bottom of the vessel is to compensate for the rise and fall of the whaler, caused by the wave motion when the whale is attached to her, and consequently these steel springs should be compressible to an extent equal to the difference between the top and the bottom of the waves. Were no accumulators, as these springs are called, provided, the strain on the rope when heaving in the whale, caused by the rise and fall of the steamer, would be greater than the strength of the line, which would consequently break, and rope, harpoon, and whale would be lost. If the whale is not shot dead on the spot, the gunner has to play it, in a very similar manner to that of the angler who has hooked a salmon. In both cases the strength of the line is very much less than the power at its extremity, and most experienced skill and care in handling have to be exercised. The whaling steamer plays the whale by manipulating the steam winch and also by moving ahead and astern, but it often happens that the line will be snapped by a sudden jerk, or a leap above the surface of the water. The whale having been raised to the surface, a chain is passed round the tail inside the flukes, and made fast at the bow ot the ship, the harpoon line is cut off at the harpoon, and the whale is towed at the side of the vessel, tail foremost. In order to make the carcass float, and to lessen its towing weight, a hole is pierced through the body into the lungs or stomach, and the whale is inflated with air by a steam air-pump in the engine-room of the whaler. If the conditions are favourable the hunt is continued until dusk, when the steamer usually heads for the reducing station to hand over the carcasses to the factory. She then steams off again as soon as possible, the object being to arrive at the whaling grounds by sunrise of the next morning.

In northern latitudes it is seldom that more than four whales are brought in during one day, but in the south, where they are much more abundant, eight to ten whales per day is not an unfrequent occurrence for one whaling steamer.

This is the method of killing and taking whales employed by all modern whaling companies. Killing and taking whales by means of rowing boats is only practised by the old-fashioned Dundee, San Francisco, and New Bedford whalers, and by the fleet of small vessels which pursue the Bottle-nosed Whale.

Reduction.

The vessels carrying on the pursuit of the Right Whale and Cachalot are constructed so as to receive the products of their catch; thus the whalebone is cut out and stowed away, and the blubber is flensed off the whale and deposited in tanks on board the whaler and discharged at her home port, where it is tried in. The American Cachalot whalers boil down the oil on the high seas.

With the modern whaler, a factory is an essential part of the equipment. These factories are of two kinds—a shore factory and a floating factory. A complete shore factory consists of plant which reduces every part of the whale carcass to merchantable products.

Nearly all the whaling stations and factories in the northern hemisphere are complete, but in the south there are comparatively few stations which do more than boil down the blubber of the whale. The distance from the markets, with the consequent expense of bringing to the factory the stores necessary for reducing the carcass and the extra freightage incurred in conveying the finished products to the markets, make it questionable whether it is a profitable business to reduce more than the blubber in such places as the South Atlantic; indeed, the work can only be conducted under any circumstances when the products are saleable at high prices.

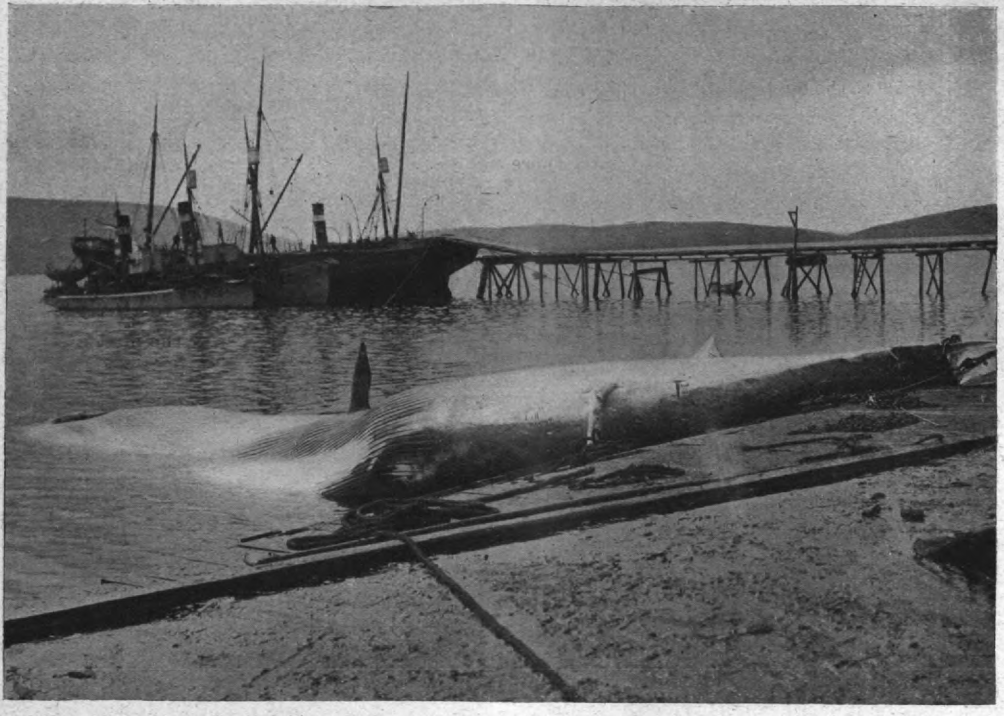

FIG. 3.—WHALE BEING PULLED UP THE SLIP ON TO THE FLENSING PLATFORM.
Three whaling steamers, moored to a coal-hulk, are seen in the background.

FIG. 4.—FLENSING A FINNER WHALE—THE FIRST CUT.

Hosted by Google

If the whale be brought to a fully-equipped shore factory, it is hauled up a slip on to the flensing platform (Figs. 3 and 4), where the whalebone or finners (as the baleen of the Finner species of whale is commonly called) are removed, the blubber cut off in strips, chopped into small pieces, and conveyed to large open vats, where the oil is extracted by means of direct steam. In Newfoundland and British Columbia the oil is usually extracted by the benzine process, but although the resultant quantities seem to be greater, the treated oil generally fetches a lower price. The tongue and kidney fat are treated similarly, but the flensed carcass has to be chopped and sawn into suitable pieces and then conveyed into large boilers, where the contents are subjected to a steam pressure of about 60 lbs. per square inch for twelve to fifteen hours continuously. During this period the oil contained in the carcass is run off into tanks. The digesters thereafter are emptied of their contents, which are passed over large open drying kilns, fired by foundry coke, and finally the dried residue is run through a disintegrator, then sifted, and finally bagged as a fine powder or meal.

Three products may be obtained from the dried meat and bones: Firstly, whale meat meal made exclusively from absolutely fresh whale flesh, the best parts only being used; this is a most nutritious and wholesome foodstuff, containing about 79 per cent. of protein. Secondly, whale guano, made from the carcass, flesh, and about one-third of bones; the analyses of this shows about 8·50 per cent. ammonia and about 21 per cent. of tribasic phosphates of lime. Thirdly, bone meal, yielding about 4 per cent. ammonia and about 50 per cent. phosphates. The whole of the dried carcass may also be made into one product, making a rich guano of great value, and containing from about 10 to 11·75 per cent. ammonia and 17 to 23 per cent. of phosphates. The present value is about 11*s.* 6*d.* per unit of ammonia, and 9*d.* per unit of phosphates.

The value of whalebone, baleen or finners, varies greatly. The product of the Greenland Right Whale is the most valuable, but the present market price can hardly be stated at more than about £1,200 to £1,500 per ton. The baleen of the southern Right Whale and the Biscay Whale is worth from £800 to £1,000 per ton, whereas the finners of the Fish Whale (*borealis*) is only about £65, Blue Whale and Finner Whale about £50, and of the Hump-backed about £25 to £27 10*s.* per ton. Very few finners of the low-priced qualities are shipped from the South Atlantic stations, as it has been demonstrated that the cost of preparing and placing them on the market is barely more than what the goods realise.

Whale oil is usually graded into four qualities: Nos. 1, 2, 3 and 4, although some companies add a fifth—No. 0. Nos. 0 and 1 are made entirely from the blubber; No. 2 from the tongue and kidney fat and from the residue of the blubber boilings; No. 3 from the flesh and bones; and No. 4 from refuse.

During last season the demand was great, and prices ruled in consequence high—£24 to £25 per ton, barrels included, being obtained for the best qualities, with from £1 to £2 per ton reduction between the grades. The prices ruling this year are very much lower, in sympathy with the values of competing seed oils.

Where circumstances, climatic or otherwise, make the erection of a shore station and factory difficult or costly, or where, owing to ice setting in, the season is a very short one, floating whaling factories are now utilised. These consist of a steamer varying from 3,000 to 8,000 tons dead weight, provided with all the necessary reducing plant, and with tanks for storing the oil. The whales are flensed in the water alongside the vessel, and the blubber hoisted on board, where it is treated in a similar manner to that adopted in the shore station. These floating factories are complete in themselves, and accommodate the whole of the crews necessary for the operations conducted, which vary from fifty to 100 hands, according to the size of the vessel and the plant fitted on board.

The power of reduction of the best-fitted floating factories is very considerable, as it is no unusual thing to dispose of twenty whales per day. Some vessels have plant fitted, not only to dry the blubber, but also to reduce the flensed carcasses, and several companies have one floating factory for boiling down the blubber alone and another which deals only with the flensed carcasses. In this way the whole carcass is utilised.

Experiments have also been made with the fitting of guano-drying plant afloat, but so far the efforts have been unsuccessful, and it is doubtful whether the expenses of reduction and marketing will be covered by the price realised for the finished products.

Species.

According to Guldberg, a Norwegian professor, there are between 140 and 160 different

Hosted by Google

species of whales, but the following are those of commercial value :—

The Greenland Right Whale (*Balaena mysticetus*) attains a length of about 60 ft., and has a very large head, about one-third of its length. The whalebone has a length of up to 15 ft., 300 to 400 pieces on each side, which command the highest prices on the market, owing to the length and quality. This is a purely Arctic species.

The Nordkaper Whale, or Biscay Right Whale (*Balaena biscayensis*), is somewhat smaller than the Greenland Right Whale, and has not such a large head. The whalebone is of a similar quality to that of the Greenland Right Whale, but the length is seldom more than 7 ft. It is most frequently found in the North Atlantic, off Ireland and the Hebrides, but specimens have also been secured off Shetland, Faroe and Iceland.

The Southern Right Whale (*Balaena australis*) is an Antarctic species, and has a length of about 45 ft. to 50 ft., and whalebone measuring up to about 7 ft. in length.

The White Whale (*Delphinapterus leocas*) is absolutely white and about 20 ft. in length. It is furnished with teeth in both the upper and lower jaws. It is a purely Arctic whale.

The Bottle-nosed Whale (*Balaenoptera hyperoodon*) has a length of about 20 ft. to 25 ft. It is principally found in the Norwegian Sea from April to July.

The Cachalot or Sperm Whale (*Physeter macrocephalus*) has a length of about 50 ft. to 60 ft., and is found on both sides of the Equator, but has also been killed in the temperate and cold zones as far as Iceland in the north and South Georgia in the south. It has an unusually large head, and teeth in the lower jaw only. In its head is found the valuable spermacetti and sperm oil. As much as ten tons may often be collected from a single whale.

The Blue Whale (*Balaenoptera sibbaldii*) is the largest living animal in the world, and attains a length of up to about 100 ft. It is found in almost all seas. The whalebone or finners are seldom more than about 3 ft. in length.

The Finner Whale (*Balaenoptera musculus*) has a length of about 70 ft. It is also found in most seas all over the world.

The Humpbacked Whale (*Megaptera boops*) is about 50 ft. in length, and has a large head, with a flat forehead. The body is short and thick. It is found nearly all over the world, more especially in the South Atlantic, from November to May, and off the coasts of South Africa and South America, and probably also off the Australian continent, from May to November.

The Fish Whale (*Balaenoptera borealis*) is usually about 40 ft. to 50 ft. in length, and is principally captured off Scotland and the Faroe Islands, in the north, and the Falkland Islands in the south. It is a whale of very small value, and is only pursued when there is a scarcity of the larger species.

Production.

During the season of 1911 there were in operation north of the Equator, about 120 modern steam whaling vessels, and the catch was about 5,000 whales, yielding about 156,000 barrels of oil of about 26,000 tons. These figures are exclusive of the Japanese fleet. The approximate value is about £625,000. Compare this with last year's result of the whalers operating at South Georgia alone. Here, with only nineteen whalers, 7,000 whales were brought in, yielding about 200,000 barrels of oil, or about 50 per cent. more whales, and nearly 40 per cent. more oil than the total result of the combined efforts of the whole whaling fleet operating in the northern hemisphere.

In the South Shetlands, twenty-two whalers bagged 3,500 whales, yielding 100,000 barrels, and South Africa's thirty whalers accounted for 4,000 whales, giving 120,000 barrels. Altogether the total catch of the eighty-six steam whalers operating in the southern hemisphere was about 17,500 whales, yielding about 500,000 barrels of oil, representing a gross value of about £1,750,000. The total value of the catch of the whaling industry for last season, excluding the Dundee, New Bedford and San Francisco, and bottle-nosed vessels, thus amounts to about £2,375,000, and from all sources may be estimated as worth between two and a half and two and three quarter million pounds sterling. The total number of whales killed was about 22,500, yielding about 620,000 barrels, or about 103,000 tons of whale oil, which constitutes a world's record, and is nearly twice as large as the catch of the season 1910. The present season is expected to eclipse its predecessor by at least 10 to 15 per cent.

The industry gives employment to about 10,000 men, manning the whaling vessels and working at the factories ashore and afloat. Of these, by far the greatest number are Norwegians, and it is they who have started all the whaling enterprises in the different parts of the world working on modern lines.

DISCUSSION.

THE CHAIRMAN said he was not qualified to speak on the subject of the paper, beyond the fact that he had been brought up in the nursery on a charming book called "Peter the Whaler," and he was afraid any remarks he made could be tendered by any person in the room. He thought everybody must have been struck while the author had been reading the paper by the amount of energy, ingenuity and resourcefulness which had been displayed by the Norwegians in the whaling industry: they seemed to have pervaded the whole of the world in their search of the whale. He recollected hearing the late Lord Granville once saying that a celebrated sportsman had told him that he had pursued every possible kind of sport, and had speculated on the Stock Exchange, but that he had never known what continuous excitement really was like until he began to manage his own farm. He (Lord Sanderson) thought the audience would agree with him that if that gentleman had gone whaling in the manner which had just been depicted on the screen, he would have experienced entirely new sensations. There was one point on which the author had not touched, as only the practical side of the question had been dealt with in the paper, and that was whether a whale was really a fish. When he (Lord Sanderson) was engaged on the Behring Sea Commission, he went to hear a lecture by Sir William Flower upon seals, and the first thing that gentleman did was to draw upon the blackboard the skeleton of a squirrel and then to surround it with the outside of a seal; and he (Lord Sanderson) believed that the whale was the skeleton of a mammal with some very undeveloped hind legs. He supposed that made it, none the less, a fish to most people, although from a zoological standpoint it was not a fish. The remark made in the paper with regard to the falling off in the northern whale fishery and the immense increase in the southern whale fishery, reminded him of a walk he once took near Dungeness. He came across a coastguardsman with an enormous telescope, who was reflecting upon shrimps, and the man remarked that when he was a little boy he was able in half an hour to get quite enough shrimps for his tea, but in consequence of the number of people now engaged in shrimping operations, and the deadly nature of the instruments employed, it took him the whole afternoon to get sufficient to feed a single infant. The man finished by saying that whatever man enjoyed, that man destroyed. He (Lord Sanderson) could not help thinking that similarly some kind of precaution ought to be taken that the whaling industry should not exhaust itself by its own efforts.

MR. BULLEN, referring to the author's phrase "old-fashioned whaling," said that no doubt operations in the past had been old-fashioned, and certainly the industry had been a very poorly paid one. He sincerely trusted that the men seen in the pictures thrown on the screen were a great deal better paid than he had been. The author was quite correct in saying that the old whaler had the advantages of not having to seek permission to hunt whales, that he was a pelagic fellow, that he went outside the three-mile limit, and so on, but he (the speaker) could very well remember being surrounded by at least three thousand sperm whales, and having to be satisfied with one, which, when they got it, took a fortnight to dispose of. Nothing could be done to it until the wind was favourable enough for the ship to get into port, and when they had stripped all the blubber they possibly could off it, the Maoris got hold of the carcass——which, perforce, had had to be cut adrift—and succeeded in getting many more pounds' worth of oil out of it. He joined issue with the author in regard to the character of the weapons that were used. The Cachalot was as huge and as hardy a creature as could be found in the ocean, and yet he had on four occasions seen a Cachalot killed within the space of three minutes by a thrust from a hand lance delivered by an experienced man. Such a man was not even in these days to be despised, because the author himself had confessed to having followed a whale for seven or eight hours before one of those tremendous 6-foot harpoons with its 11 lbs. of gunpowder to blow the whale's inside out could be planted in the whale's body. Two years ago he was on the coast of Bahia going to Buenos Ayres, and he saw something like 25,000 whales; the ocean was covered with them, and the only people engaged in hunting them were those people of which the author spoke, and justly, with a tinge of scorn, the natives of the Brazilian coast—who, he thought, were born tired, and whose only ambition seemed to be to prevent anybody else from doing work which they would not do themselves. He understoood that state of affairs was going to be altered in the future. He thought he could safely voice the opinion of the audience in thanking the author very warmly for his paper. In conclusion, he would warn the southern whalers that they had better make hay while the sun shone, as if seven whalers were getting 7,000 whales in one spot, it would not be very long before the southern whale fishery would follow the northern whale fishery, and the whales would practically disappear from the sea.

On the motion of the CHAIRMAN a hearty vote of thanks was accorded to the author for his interesting paper, and the meeting terminated.

DISTRESSED INDIAN STUDENTS' AID COMMITTEE.

The first annual report of this Committee, which has just been issued, affords some interesting reading. The Committee, which is under the chairmanship of Sir James Wilson, K.C.S.I., with offices at the Indian Students' Centre, 21, Cromwell

Hosted by Google

Road, S.W., was formed for the purpose of collecting, receiving and distributing money given in private charity, or from public funds, for the benefit of Indian students in pecuniary difficulties in this country.

The objects of the Committee are:—(1) To assist deserving cases of temporary distress; (2) In case of remittances being delayed, to help the applicant with a loan; (3) to help students who have no means of subsistence in this country to return to their own homes; (4) to obtain the repayment of advances made or other necessary funds from the student's relations or friends in India; (5) to save charitable persons in this country from being imposed upon by undeserving applicants.

At present there are believed to be in this country about 1,700 Indian students, of whom some 1,000 are working in London. During the past year the Committee dealt with applications from thirty-eight Indians of various castes and creeds belonging to different Provinces and Native States.

The report contains a paragraph relating to the cost of study in Europe and the equipment that should be possessed by an Indian student before deciding to come to this country, which deserves to be quoted in full:—

"Our experience of the distressing cases with which we have had to deal leads us to urge earnestly on all parents in India, and on others having influence over young Indians who may think of coming to this country to study, the duty incumbent on them of discouraging any student from carrying out such an intention until full provision has been made for the expenses he must necessarily incur in order to obtain any real advantage from his stay in England. It is hardly possible for an Indian student to complete a course of education in this country, and to obtain a call to the Bar, or a degree or diploma which will be of any use to him in after life, at a cost for passage, fees, clothes, books, board and lodging of less than Rs. 10,000, and no Indian parent should allow his son to come to England for study unless he can see his way to provide this sum without unduly crippling his own resources. Many students cost their families Rs. 12,000 or Rs. 15,000, and it would be wise to count on the possibility of having to provide as much as this. It is also of great importance that no Indian student should leave India for England until he has acquired a thorough knowledge of English and a good general education, and if possible a degree of an Indian university. While the majority of Indian students here are diligent and well-behaved, and make a good use of their time, and go back to India with a more thorough knowledge and wider views, we have met with too many cases in which it is obvious that the youth should not have been allowed to come to this country at all, and that he will ultimately have to return to India a failure, after having cost his family much more than they could spare, and having possibly himself, owing to imperfect education or insufficient pecuniary resources, become degraded, instead of improved, in character. The Committee will be glad if, in consequence of their labours, such cases become fewer in number, to the advantage of the young men themselves, of their families, and of the whole body of Indian students."

EXHIBITION OF OLD MASTERS AT NICE.

A collection of works of the old painters of the Nicene school, "Les primitifs Niçois," is being shown by the Société des Beaux Arts of Nice. These paintings, which occupy several rooms at the Municipal Museum, are interesting specimens of local art of the fourteenth and fifteenth centuries. The collection consists chiefly of altar-pieces, tryptichs and panels lent by the owners, and in many cases the paintings are remarkable for the intense religious feeling which must have inspired their authors. Many of these works were discovered in the churches, monasteries and shrines, in out-of-the-way mountain villages or in the small towns in the Maritime Alps. Two rooms are devoted to tracings from frescoes. Those from the chapel of St. Maur at Saint-Etienne-de-Tinée, representing the martyrdom of St. Sebastian, and another of the martyrdom of St. Bernard, from Venanson, painted in 1480, may be noted as especially bold in treatment. A fresco by Canavasi, painted in the middle of the fifteenth century, from the chapel of St. Sebastian at La Tinée, and many others including the works of Gaspard Nadal and Currandi Brévisi in 1493, from the chapel of La Tour, are remarkable for their purity of style and treatment.

A third room contains a number of paintings lent by the Principality of Monaco, consisting chiefly of altar-pieces.

Especially worthy of attention is "The Descent from the Cross," by Lodovico Bréa, painted in 1505. This is surrounded by six panels representing various scenes in the Passion of Christ. Two other panels representing St. John the Baptist and St. Vincent, by an unknown painter, are remarkable for their harmonious colouring.

The great altar-piece belonging to the church of St. Nicolas, painted by Lodovico Bréa in 1500, in which the patron saint occupies the centre panel, and St. Michael and St. Madeleine with other saints on a background of gold the sides, is well worth attention.

Another altar-piece, from the Church of the White Penitents at Monaco, is interesting on account of a landscape showing La Condamine as it appeared in 1520.

Amongst the gems in this collection worthy of note, must be mentioned the altar-piece in five compartments from Bouyon, another from Vence, painted in 1450 by Jacques de Carolis, representing

Journal of the Royal Society of Arts.

No. 3,098. VOL. LX.

FRIDAY, APRIL 5, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

CANTOR LECTURE.

On Monday evening, April 1st, Mr. Noel Heaton delivered the third and final lecture of his course on "Materials and Methods of Decorative Painting."

On the motion of the Chairman a vote of thanks was accorded to Mr. Heaton for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

THE ROYAL SOCIETY OF ARTS.*

By Sir Henry Trueman Wood, M.A.,
Secretary of the Society.

VII.—The Officials. The Transactions. The Council. The Charter. (1761–1847.)

On the death of Lord Folkestone in 1761, Lord Romney was elected President, and he held the office till his own death in 1793. From its foundation, he had always taken the greatest interest in the Society, and during his presidency he continued to attend regularly. There is no doubt that the Society owed a great deal of its early success to its first two presidents.

During Lord Romney's presidency a proposal was made that the Prince of Wales should be elected patron, and His Royal Highness seems to have agreed. At the meeting of the Society on December 14th, 1785, a letter was read from Caleb Whitefoord,† saying that the Prince would become patron, and the proposal was approved. However, at the meeting of the following week (December 21st) other counsels prevailed, and the consideration of the question was "postponed," not to be revived. The reasons for this action are veiled in what was perhaps a judicious reticence.

Lord Romney died in November, 1793, and was succeeded in the following year by the Duke of Norfolk. The Duke had been elected a member of the Society in May, 1769, as Charles Howard, jun., his father, also Charles Howard, having become a member in 1758. The elder Howard became tenth Duke of Norfolk in 1777, when his son became Earl of Surrey. The tenth Duke died in 1786, when he was succeeded by his son as eleventh Duke. He was made a Vice-President in 1791, and was elected President at the election of officers in 1794.

He was a man of considerable natural ability and of independent character. He was distinctly eccentric, and was a frequent subject for Gillray's caricatures. Slovenly in his habits and dress, and too much addicted to conviviality, he was yet a liberal patron of literature and the arts, a ready speaker, and endowed with plenty of common sense. He was extremely popular, especially in Cumberland, and in the borough of Carlisle, which he represented for some time in Parliament. But he lacked self-control, and allowed himself a licence in speech and behaviour for which only his great rank procured toleration. He insulted the King, and was deprived of certain of his commissions. At

* The previous articles of the series appeared in the *Journals* of June 9th and 16th, September 22nd and 29th, November 3rd, 1911, and January 12th, 19th and 26th, 1912.

† Caleb Whitefoord was for long a prominent member of the Society. He was a friend of Franklin, being his neighbour in Craven Street, and was proposed by him in January, 1762. He continued a member till his death in 1810. He was then a Vice-President, having been elected in 1800, and for many years, from 1786 onwards, he served as Chairman of the Committee of Polite Arts. He was Secretary to the Commission which concluded peace with America in 1781, but had a greater reputation as a wit than as a diplomatist. Burke described him as nothing more than a *diseur de bons mots*, but he was well known and popular in Society. He was a friend of Johnson, Goldsmith, Garrick and Foote. The Society possesses a portrait of him painted by an unknown artist, and another portrait, engraved by Holl from a painting by Stuart, forms the frontispiece of Vol. XXIX. of the *Transactions*. He presented Templeman's portrait to the Society, and was also instrumental in obtaining the portrait of Shipley. A short memoir of him is included in the preface to the volume of the *Transactions* above mentioned.

Hosted by Google

one time he was intimate with the Prince of Wales, but they quarrelled. Their reconciliation was celebrated by the disgraceful practical joke played upon the Duke in his old age by the Prince, and described in scathing language by Thackeray in the "Four Georges." The Duke, himself a sufficiently seasoned toper, was invited from Arundel to the Pavilion at Brighton, and there made most disgracefully drunk. Readers of Thackeray's brilliant, but very one-sided, essays will remember the sorry story well enough.

He certainly did not take the same keen personal interest in the Society's welfare as did his two predecessors, but he made a good and attentive President, and at all events performed efficiently the ceremonial functions of his office. He attended regularly at the annual distribution of prizes, and occasionally at other meetings when important business had to be transacted. It was owing to the Duke's objection to the proposal that the resolution giving permission to Barry in 1801 to substitute portraits of King George III. and Queen Caroline for those of Lords Folkestone and Romney, then in the Great Room, was rescinded.*

The Duke of Norfolk died in December, 1815, and his death was formally reported at the ordinary meeting of the Society on the 20th of that month. At the next meeting, on January 10th, 1816, it was proposed that the Duke of Sussex should be nominated in his stead. His Grace was a member of some four years standing, he having been elected in April, 1811, when he paid the usual life membership fee of £21. An extraordinary meeting was called for February 1st, and His Royal Highness was elected by 180 votes to twenty-four over the Earl of Liverpool, who had also been proposed. At the same meeting a deputation was appointed to wait on the Duke and to invite him to accept the presidency. The deputation was received at Kensington Palace on the twelfth of the same month. The Duke made a very courteous and complimentary reply to the elaborate address presented by the deputation, and accepted the office, apparently with some gratification. He attended the next meeting of the Society two days later (February 12th, 1816), was duly inducted into the chair, and conducted the regular business of the meeting.

The sixth son of George III., the Duke of Sussex was a man of liberal sentiments, genial manners and intellectual tastes. He took a genuine interest in art and in science, and was well qualified for such a post as the presidency. He liked the work, and did it well, and enjoyed acting as figure-head on all ceremonial occasions. Afterwards (from 1830 to 1839) he acted as President of the Royal Society, and in both offices he made himself popular. That he should take any active share in the management of either society was not to be expected, but he was always ready to attend any functions which required his presence, and discharged the duties required on such occasions with unvarying amiability and dignity.

So far as the Society of Arts was concerned, the most important functions for its President were the annual dinner and the annual distribution of premiums. The latter ceremonial was for many years held in the Society's own room, but the attendance grew too large for the limited accommodation, and after a good deal of consideration, when it became clear, after several years' experience of inconvenient crowding, that the meeting-room was too small for the numbers attending, a move was made in 1816 to Freemasons' Hall. In 1820 the distribution was held in the Argyll Rooms,* and in 1822, as the crowds still grew, Drury Lane Theatre was hired for the occasion. It is clear that the event had become an important social function. There was a military band, a body of stewards was organised, and a staff of policemen engaged. Altogether it was a very important ceremonial, requiring not a little fuss and organisation. The secretary was required to deliver an appropriate address—two of Aikin's are printed in the *Transactions*.

For some years these celebrations were continued at Drury Lane or at the King's Theatre,† but in 1829, either the attractions of the ceremony had diminished, or the diminishing funds of the Society rendered economy desirable, and it was decided to return to the more modest arrangement of a prize distribution in the Society's Great Room. In that year two separate meetings were arranged, one for the prizes in Polite Arts, and the second a month later for the other awards. In the following year a single meeting only was held and all the prizes were presented on the same day. This arrangement, however, was not popular, and in 1831 Exeter Hall was engaged. The same plan was followed

* *Journal*, Vol. LIX., September 22nd, 1911, p. 1021.

* These Rooms were on the east side of Regent Street, at the corner of Little Argyll Street. They were built by Nash in 1818, and must not be confounded with the Argyll Rooms in Windmill Street, which, as Mr. Wheatley says in "London Past and Present," acquired an "unsavoury reputation" and had no history.

† The King's Theatre or Haymarket Opera House, later known as Her Majesty's Theatre.

for the next four years. Then for three years (1836 to 1838) the Society went to the Hanover Square Rooms, and in 1839, again hampered by failing resources, it came back to the Adelphi and had its annual distribution in its own meeting room.

In June, 1840, the Duke of Sussex proposed Prince Albert for membership of the Society, and he was at once elected. The Duke of Northumberland and Lord Radnor were his other sponsors. His Royal Highness qualified as a life member. His marriage with Queen Victoria had taken place in the previous February, when an address was presented by the Society to Her Majesty.

Three years later, in April, 1843, the Duke died, and it was at once determined to invite Prince Albert to succeed him. A deputation of three of the most distinguished Vice-Presidents—the Duke of Buccleuch, the Duke of Sutherland, and the Marquis of Northampton—was appointed to invite H.R.H. to accept the presidency. The Prince at once acceded, and was elected president on May 26th of the same year. He entered on his duties by presiding at the annual distribution of awards in June.

The number of Vice-Presidents varied from time to time. There were twelve at the end of the eighteenth century, nearly all great noblemen, with a few distinguished men, who took a more active share in the Society's proceedings. The numbers were increased to about twenty later, most of the additions being of the latter class, more or less active workers, and in 1843 a distinction was actually drawn between the "Honorary" and the "Acting" Vice-Presidents. There were also eighteen Chairmen of Committees, two for each of the nine Committees, which remained unchanged for very many years. These were the six Premium Committees—Arts, Agriculture, Manufactures, Mechanics, Chemistry, Colonies and Trade, with three others—Accounts, Correspondence and Papers, and Miscellaneous Matters.

The paid officials were the Secretary, Assistant-Secretary, Registrar and Collector. These, with the President, Vice-Presidents, and Chairmen of Committees, were all elected at the annual meeting.

Dr. Templeman* was succeeded as secretary by Samuel More, who had indeed discharged most of the duties of the office during the long illness which preceded Templeman's death. He held the post for over thirty years, for he was elected in January, 1769 (Templeman died in the preceding October), and died in October, 1799, at the age of seventy-four. He was evidently a capable and efficient secretary, keenly interested in the Society's work. He had been an active member for some ten years before he became secretary, and seems to have been both respected and popular. Of his private life not very much is recorded. A short paragraph in the *Gentleman's Magazine* reports his death, and in the Preface to Vol. XVIII. of the *Transactions* there are some laudatory comments on his work. No biographical information is given, "because it is expected that a full account of him will be prefixed to the publication of some valuable papers which it is said he has bequeathed to the world." This intention, however, does not appear to have been carried out, as no trace of such a publication can be found.

The estimation in which he was held by the members is shown by the fact that he was presented with a gold medal in 1794 "For eminent services," and also by the inclusion of his portrait in Barry's picture, "The Society." His portrait was also painted for the Society by Benjamin West, P.R.A., in 1796. A fine engraving of the picture was made by W. Sharp.* He contributed two papers to the *Philosophical Transactions*,† and one, on standards for weights and measures, to the Society's *Transactions*,‡ besides his unsigned contributions.

It was during More's secretaryship that the *Transactions* were commenced. The need of some permanent record of the Society's proceedings was recognised at a very early date. It was obviously of little use to stimulate invention or to reward progress, unless full information of the results obtained could be made public. The Society soon became possessed of a good deal of valuable information contributed by the competitors for the awards, and this it was at first proposed to publish in a "Historical Register," arrangements for the preparation of which, it appears from the minutes, were on several occasions discussed. Instructions were given to Templeman to prepare such a Register, and two MS. volumes are in existence, apparently bound at a later date, and entitled "Dr. Templeman's Transactions." These, however, consist merely of extracts and compilations from the minutes, a copy of the

1759 premium list, the "Rules and Orders," a list of members elected from April, 1755, to April, 1758, and similar matter. There are only two documents of any importance. One is a manuscript copy of the pamphlet published in 1721, containing a proposal for the formation of a London "Chamber of Arts," referred to in the first article of this series.* As no copy of this pamphlet, so far as the present writer is aware, has been preserved, Dr. Templeman's MS. copy is of interest. The scheme suggested is so much like that of the Society, that it looks as if Shipley, or some of the founders, was familiar with the proposal. There is also a copy of a draft charter for an Academy of Arts without any date. This was no doubt the draft submitted to the Society in 1755 by Sir Henry Cheer, but not approved. It is very full and complete, but the scheme was one for an Academy of Arts, not for an industrial Society, such as was really in the minds of the founders of the Society of Arts.

On the whole, it is fairly evident from the contents of these volumes that if Dr. Templeman had been able to complete and publish his "Historical Register," it would not have added very much to the information available about the Society's early years.

According to a statement of Arthur Young's,† a good many of the communications made to the Society were published as pamphlets, in the book "De Re Rustica,"‡ in the *Gentleman's Magazine*, or in other periodicals. Descriptions of some of the machines rewarded by the Society are to be found in an illustrated work entitled "The Advancement of Art, Manufactures, and Commerce, or Descriptions of the Useful Machines and Models contained in the Repository of the Society," published in 1772, by William Bailey, who was then Registrar to the Society. It is a quarto volume with a collection of fine illustrations in folio. In 1782 another edition was issued by A. M. Bailey, who succeeded his father as Registrar in 1773. It is in two volumes, folio. The book is of some value, as it contains accounts of several pieces of apparatus not elsewhere described, and the illustrations are very good.

The first publication, however, which regularly published a selection from the proceedings of the Society was the *Museum Rusticum et Commerciale*, a monthly journal, of which six volumes were issued, each containing six of the monthly parts. This commenced in 1764 and came to an end in 1766. It had no official connection with the Society, but it provided a means of publication for some, at all events, of the more important and interesting matters which were brought before it, though it was by no means restricted to the Society's proceedings.*

This casual and unofficial method of publication proved unsatisfactory, and its failure suggested to Robert Dossie, an active member of the Society, the production of a similar work which should contain such memoirs as the Society desired to publish, together with other contributions, and also selections from the published proceedings of foreign societies devoted to the Arts and Sciences. An arrangement was entered into between Dossie and the Society, under which he undertook to publish, and they to provide, such communications as seemed suitable to both parties. With this understanding, Dossie started his "Memoirs of Agriculture and other Oeconomical Arts," the first volume of which was published in 1768, and contains a resolution, passed by the Society in June, 1767, to the effect that they "will occasionally publish in this Work such Pieces as they shall think proper to lay before the Public." It is entirely made up of the Society's proceedings, and begins with a list of all the awards, other than those in Polite Arts, up to end of 1767; next follows a brief statement of the Society's receipts and expenditure to the same date; and after this is a well-written and excellent account of the Society's proceedings, presumably prepared by Dossie himself. This occupies the greater part of the book, and it is in these pages that the whole early history of the Society is to be found. The last hundred pages contain seven articles, all but one devoted to agricultural subjects, the one exception being an account of the methods for dyeing Turkey leather, for disclosing which a reward had been granted to one Philippo. This first volume was followed by two others, Vol. II. in 1771, and Vol. III. in 1782. The later volumes contain a few articles besides those contributed by the Society, and are for the most part devoted to agricultural subjects. Vol. III. continues the list of awards down to the year 1776, and also gives a complete list of the premiums in "Polite

‡ "De Re Rustica, or the Repository for Select Papers in Agriculture, Arts and Manufactures." London: Two Vols., 8vo., 1771.

* Two of the chief contributors to the *Museum* were Arthur Young and Robert Dossie. Young states in his Autobiography (edition of 1898 by M. Betham-Edwards, p. 33) that the "Farmer's Letters" consisted of his scattered papers in the *Museum Rusticum*, which, at the suggestion of the Rev. Walter Harte, he republished, with additions, in a volume. Dossie contributed several articles signed "Agricola," and possibly other papers.

Hosted by Google

Arts" down to the same year, with some useful biographical notes about the prize-winners. Dossie's intention of continuing the general history of the Society was, unfortunately, never fulfilled, and, indeed, it is probable that it was interrupted by his death, which happened certainly not later than 1783. The catalogue of the Advocates' Library gives 1777 as the date, but this can hardly be correct. In Vol. II. of the Society's *Transactions* (published in 1784), he is referred to as the "late Mr. Dossie," and the preface to Vol. III. of the "Memoirs of Agriculture" (1782) is signed by him.

Not very much is known of Robert Dossie, who was certainly a skilful chemist, and an accomplished writer. He was a friend of Dr. Johnson's, and almost the only reference to him which appears in contemporary literature is to be found in Boswell:—

"Johnson was well acquainted with Mr. Dossie, author of a treatise on agriculture, and said of him, 'Sir, of the objects which the Society of Arts have chiefly in view, the chymical effects of bodies operating upon other bodies, he knows more than almost any man.' Johnson, in order to give Mr. Dossie his vote to be a member of the Society, paid up an arrear which had run on for two years."*

There is a short and inaccurate notice of him in Donaldson's "Agricultural Biographies," and beyond this there seems nothing beyond scattered references in the Society's records, and his own books. He was the author of several works on chemistry, and he was connected, as a contributor, if in no other way, with the *Museum Rusticum.* He received a gold medal from the Society in 1766 for "aiding to establish the manufacture of potash in North America," and before this, in 1761, he had received a grant of £100 for his method of purifying oil. As he was a member at the time this would appear to have been irregular, as members were not eligible for money prizes, but the grant was made in consideration of the expense to which he had been put in experimenting, and no doubt this was considered sufficient justification. He was a candidate for the office of secretary in 1760, when Dr. Templeman was elected, and it was after his failure to secure this office that he became a member. He was an active and useful member of the Society, and a frequent attendant at its committees.

* "Boswell's Life of Johnson," Birkbeck Hill's Edition, 1887, Vol. IV. p. 11. Dr. Johnson paid two years' subscriptions on March 25th, 1760. Dossie was elected on April 2nd of the same year.

It may have been Dossie's death, and the consequent discontinuance of the "Memoirs of Agriculture," that brought to a head the proposals for a regular series of *Transactions.* Valentine Green claimed the credit for carrying the proposal through, and from the minutes it appears that the final decision to publish transactions was due to his efforts, but Arthur Young, apparently with justice, claims to have originated the idea. In his autobiography he says,* under the date 1772:—"This year I attended very much the meetings of the Society for the encouragement of Arts, Manufactures and Commerce, as well as the Committee of Agriculture, of which I was chairman. In a letter from Mr. Butterworth Bayley, he lamented the want of a respectable publication by the Society of Arts, and called on me to think of some means of remedying the misery. When I became chairman of the Committee of Agriculture, I was the first to propose that annual publication which afterwards took place. This proposition was at once acceded to, and Valentine Green, the engraver, had the impudence to assert that it originated with him."

In this Young probably refers to his remarks above referred to in the "Farmer's Letters" of 1771, in which he dwells very earnestly and with much force on the necessity of the Society publishing *Transactions,* and points out that the value of the premiums, though in some cases they are "truly munificent," is greatly lessened by the absence of any published record.

The first volume of the *Transactions* was published in 1783. It compares rather unfavourably with Dossie's skilful compilation. The original papers are neither numerous nor important, and the bulk of the volume is made up of mere official records, necessary but insufficient by themselves. Subsequent volumes show a marked improvement, and the records of the Society's proceedings bear a more reasonable proportion to the purely official matter. The series was continued to 1844, when it ceased with Vol. LV.† Up to 1830 an annual volume was published, but from that date to 1843 (Vols. XLVIII. to LIV.) each volume consisted of two annual parts. Vol. LV. contains only the proceedings of a single session, that of 1843–4. In 1848, a few years later, an attempt was made to start a new series, and a volume was published purporting to

† A general index to the contents of previous volumes of the *Transactions* is given in Vols. XXVI. (1808), XL. (1823), and L. (1836).

Hosted by Google

contain the proceedings for the sessions 1846–7 and 1847–8. It is a handsome quarto volume, containing some good illustrations, a selection of papers read before the Society, and the Charter. This was eventually treated as Vol. LVI., though on the titlepage (which bears the date 1852) it is called a "Supplemental Volume." In December, 1851, a volume, called Vol. LVII., was published, containing the proceedings for the session 1850–1. It corresponds in form with the original series, and is in no sense a continuation of Vol. LVI. After this no further *Transactions* were published.

In 1845 there was commenced an issue of a publication called the "Abstract of Proceedings." This was published weekly during the session while meetings were being held. At first it consisted only of a few octavo pages of notices and general information about the Society, but from 1848 onwards it contained abstracts of the papers read. A little later it was entitled "Weekly Proceedings," and in this form it continued till the end of the session for 1851–2, the last number being dated July 17th, 1852. The number for June 12th contains a note stating that the Council were considering the publication of "a stamped weekly Journal," and with the new session the *Journal of the Society of Arts* was started. The first number of the Journal was published on November 26th, 1852.

After the death of More in October, 1799, the usual steps were taken for the election of a new secretary. Amongst the candidates who applied, besides Charles Taylor, who was successful, were included the Rev. Edmund Cartwright, the inventor of the power-loom, and Valentine Green.* Valentine Green had for very many years taken a leading part in the Society's affairs, but he had been involved in a very serious loss by the failure of his scheme for publishing the collection of prints from the pictures in the Dusseldorf Gallery. It was no doubt this which made him apply for the secretaryship, as it afterwards led him, on the foundation of the British Institution in 1805, to accept the office of Keeper. The committee, which subjected all the candidates to a severe catechising, rejected Green, but recommended as qualified Taylor, Cartwright and another.

* Valentine Green (1739–1813), the well-known mezzotint engraver, was a member of the Society from 1772 till his death. He was one of the most regular attendants and took an active share in its proceedings. He was Chairman of the Committee of Polite Arts from 1780 to 1786, and Chairman of the Committee of Correspondence and Papers from 1787 to 1797. In 1773 he received a gold medal "For repeated services."

Cartwright submitted a special memorial of his qualifications, which was afterwards published* in a volume together with some further information relating to his improvements in the steam engine, and his mechanical inventions. Much of the matter it contains was incorporated in the memoir of his life afterwards published by his daughter, Mary Strickland. His qualifications were considerable, for his experience not only of textile machinery, but also of agriculture, was very great. He received three medals from the Society, a silver medal in 1803 for a plough, a gold medal in 1816 for a horse gear, and a gold medal in 1817 for experiments on manures. Shortly before the date of the election, Cartwright withdrew, and this left the field practically open for Taylor, who was elected by a large majority.

Taylor was an accomplished chemist, and, according to his statement to the committee, he was known to almost all the chemists in Europe. He informed the committee that he was the inventor of a method of calico printing "by wooden cylinders and sliding metallic cylinders." He also claimed to have furnished the Government with valuable information on indigo, which had led in the eight years from 1789 to 1797 to an increase in the value of the export of indigo from the East Indies from £110,000 to £558,000. Taylor was for some time engaged in the cotton manufacture in Manchester, but, as the short notice which appeared in the *Transactions* after his death states, "the opulence which flowed so exuberantly to many of his fellow-townsmen did not find its way to him."† He was also among the first to utilise Berthollet's discovery of the applicability of chlorine for bleaching, and was said to be "the first to produce for sale in the Manchester market an entire piece of calico bleached by oxy-muriatic acid." His death took place in 1816, after sixteen years' service. He appears to have devoted himself energetically to his duties, and to have made an efficient secretary, without being a man of scientific eminence.

Arthur Aikin, who succeeded Taylor in the secretaryship, had, even when he was elected in 1817, though he was then only about thirty-four years of age, acquired a much greater scientific reputation than his predecessor. He had already been one of the founders of the Geological Society, which was established in 1807, and had published,

* "A Memorial read to the Society of Arts . . . With an Appendix." 1800.

† *Transactions*, Vol. XXXV. (1818) p. 8.

Hosted by Google

in connection with his brother Charles, a dictionary of chemistry and mineralogy and some other works. From 1811 he had been honorary secretary of the Geological Society. He was an accomplished chemist, and was familiar with several branches of industrial chemistry. He told the committee, on his examination for the post of secretary, that he was then occupied in drawing up patents, and in advising on scientific matters. He had also a very considerable knowledge of metallurgy, and was a good botanist. He was the eldest son of John Aikin, M.D., a brother of Lucy Aikin, and a nephew of Mrs. Barbauld. His father was a friend of Priestley, and it was his association with that distinguished philosopher that led Arthur Aikin to the study of science. He was first intended for the Unitarian ministry, but he abandoned this idea in early life, and devoted himself entirely to science. He held the office of secretary for twenty-three years, and on his resignation in 1840, he became chairman of the Committee on Chemistry. He also became the first treasurer of the Chemical Society, which was founded in 1841 at a meeting held in the Society's room, and afterwards (1843–45) its President. He was never married, and died in 1854.*

To Aikin was certainly due the initiative of a change in the Society's methods, which ultimately had the result of turning the Society from a purely premium-giving body into one whose main object became the dissemination of information about the industrial arts and sciences, and the publication of new discoveries and inventions of an industrial character. The change was not effected during Aikin's secretaryship, but it was certainly completed before his death, though that completion was effected by other hands than his. The foundation was laid by his proposal that courses of lectures on manufactures should be organised, and arrangements made for the reading and discussion of papers at the evening meetings.

So far as the lectures were concerned Aikin not only suggested that they should be given, but gave them himself. From 1829, when the scheme was first started, to 1842, after he had resigned the secretaryship, he continued to deliver, year after year, excellent and well-illustrated courses on various branches of manufacture. The subjects were very varied. They include glass, pottery, paper-making, furs, tanning, silk, sugar, artificial lighting, timber, horn and tortoiseshell, and other equally divergent topics. At first practically the whole of the work was carried out, and very efficiently carried out, by the secretary, though after two or three years Aikin only gave one or two of the "illustrations," and the bulk of the work was taken over by others. The lectures were much appreciated, and did something to keep up the waning popularity and reputation of the Society. Aikin received no payment for the work, and a proposal in 1831 to present him with a gold medal was not carried, though the award was fully merited, and might well have been given. There is nothing in the minutes to show why the proposal was not adopted, but it appears that Aikin himself declined it, on the ground that he was an officer of the Society. At all events, a vote of thanks was substituted, couched in very warm and complimentary terms. Before he resigned his office, however, a testimonial was presented to him, in the form of a valuable microscope, with an inscription testifying to the esteem in which he was held, and to the value at which his services to the Society were rated. The instrument is now in the possession of his grand-nephew. However, he got his gold medal eventually, for when he retired in 1839 it was voted to him unanimously, and he was also made a life member. Few compliments could have been better deserved, for during his twenty-two years' service he devoted himself earnestly to the Society, and it was certainly no fault of his that his single-minded efforts were not entirely successful. In after years his labours bore fruit, and he lived long enough to see their results.

Even more important as regards its permanent effects was the substitution of papers and discussions at the ordinary meetings for the mere consideration of inventions competing for prizes. There is no definite evidence in the records to prove that this was Aikin's doing, but there is not much doubt that it was due to his initiative. Among the suggestions made in 1828 for rendering the meetings more attractive was one that, instead of confining the discussions to inventions submitted for awards, a notice should be issued that the Society would welcome communications of interest on suitable subjects for reading and consideration only. Such papers had indeed always been received, and, if considered worthy, printed in the *Transactions.* As far back as 1784, Daines Barrington made two interesting communications to the Society, one on silk

---

* The first regular meeting of the Chemical Society was held on March 30th, 1841. After this, for some time, its meetings were held fortnightly at the Society of Arts' House. See *Gentleman's Magazine* (N.S.), Vol. XV. pt. 1, p. 527.

Hosted by Google

and one on tobacco, and both were published in the second volume of the *Transactions*. But such papers were rare, and it was considered to be contrary to the spirit of the Society to invite them, because it looked like holding out an offer of a prize and so prejudging the decision of the members. It was, however, realised that publication was often more important than the grant of a medal, and that many inventors and students would welcome the chance of publishing their ideas who would not care to enter in competition for a prize, or might, for various reasons, not be eligible, if they did. Accordingly a notice was issued in the *Transactions* for 1829, that papers would be received for reading and publication only. The proposal proved popular, and before long such papers were found to be among the most important contributions to the annual volume. The system gradually developed, until in another ten years we find that the reading of such papers came to be the most important business of the meetings, as eventually it became the most important business of the Society. And when, as we shall see later, the whole proceedings of the Society were reformed, a special committee was appointed to secure suitable papers. At first they were only printed in abstract, but even in this form they are interesting, and among them are many communications of importance.

It was in May, 1839, that Aikin sent in his resignation, but he did not actually retire till the beginning of the new session in the autumn. In December, W. A. Graham was elected as his successor, but he only held office for three years, for he resigned in December, 1842.

During the period covered by the secretaryships of Templeman, More, Taylor, and Aikin, there were many changes in the staff of the Society. As stated in a previous article, Box became assistant secretary on the appointment of Templeman as secretary. He held the office till 1779, when he retired from failing health, having served the Society in various capacities for twenty-three years. Till 1771 he also acted as collector, when he gave up this part of his duties, no doubt in consequence of his health, which, it appears, was but feeble for some years before he actually resigned. He was succeeded as collector by Abraham Brockelbank, the man who was first appointed (Thomas Dawson) being discharged after a few months, because he was unable to find the necessary security. As assistant secretary he was followed by Richard Samuel, who was elected in May, 1779. He died in the summer of 1787, and was followed by John Samuel, presumably a relation, who was first appointed temporarily to do the work, and was formally elected in November, 1787. He served for a little over ten years, and died just before the annual election of officers in March, 1798, when the post of assistant secretary was left vacant. Bowman, the collector, was engaged to fill the vacancy, pending the regular appointment of a new assistant secretary, and in April, 1798, Thomas Taylor was elected.

Taylor, known as the "Platonist," was distinctly an eccentric character. He was an ardent student of the Greek philosophers and of mathematical philosophy, though he was absolutely unqualified either by aptitude or education to appreciate either branch of knowledge. He was the son of a London stay-maker, and was born in 1758. Though he was at St. Paul's School for three years, he does not seem to have profited much by the teaching he got there. After serving as an usher in a Paddington school he obtained a clerkship in Lubbock's Bank, and appears to have eked out his moderate financial resources by literary hackwork. Being lucky enough to have an annuity of £100 left to him, he gave up his clerkship, and applied for the assistant secretaryship. He held the post for seven years, till November, 1805, when he resigned on the ground of ill-health. He wrote in a very desponding tone about his health, but recovered, and lived for another thirty years, devoting himself assiduously to the work of translating and expounding the writings of the ancient philosophers. "His equipment for this enterprise left much to be desired. Critical faculty he had none. No doubt of the historic personality of Orpheus or the authenticity of the hymns ascribed to him ever crossed his mind; the mystical neo-Pythagorean mathematics he esteemed the true science, which the Arabians and their European successors had corrupted. . . . But with an ardour which neither neglect nor contempt could damp, he plodded laboriously on until he had achieved a work never so much as contemplated in its entirety by any of his predecessors."* This is rather a hard saying, but it appears to be justified. Still, Taylor seems to have been a kindly and amiable character. Although he was, and probably always will be, regarded as a half-crazy enthusiast, he had many friends, and appears to have been much liked. The list of his translations and dissertations occupies nearly three columns of the "Dictionary of National Biography,"

* Life of Taylor, by J. M. Rigg, in the "Dictionary of National Biography."

Hosted by Google

so he was a most laborious and industrious author. The best, perhaps, that can be said of his writings is that they were voluminous. They were certainly but little appreciated when they were written, and the lapse of time has added neither interest nor value. He died in 1835.

When Taylor resigned, his post was temporarily filled by John Taylor, who was apparently a relation, perhaps his son, as he is spoken of as "Mr. Taylor, jun.," and in February, 1806, Charles Combe was appointed. He only held the post for less than a year, for he resigned in January, 1807, and in the following March Thomas Woodfall was appointed. He was a son of William Woodfall, a brother of Henry Sampson Woodfall, the publisher of "Junius's Letters," and the conductor of the *Public Advertiser*. William was a journalist and reporter, endowed with an extraordinary memory, on which he relied for his reports. Thomas Woodfall had a printing business, which he was allowed to retain after he became assistant secretary, and he seems to have done some of the Society's printing. He continued in the Society's service till 1842.

When, in October, 1760, Shipley resigned the office of Registrar (the title is always spelt "register"), he was succeeded by E. G. Tuckwell, who continued in office till 1766. On his resignation William Bailey was appointed. His excellent account of the machines and models in the Society's collection has already been referred to in these articles. He died in January, 1773, and the post was given to his son, Alexander Mabyn Bailey. He held it for six years, but resigned in March, 1779, to avoid discharge. He seems not to have given satisfaction, and the Society, for some reason, disapproved of his action in bringing out a second edition of his father's book, or, at all events, in soliciting subscriptions for it. This second edition was, however, duly brought out, and, so far as the work itself goes, it is a credit to the Society.

He was succeeded by a man whose name was associated with the Society for nearly eighty years. George Cockings was appointed porter in November, 1765, in place of a man discharged for accepting a gratuity of £5 from a candidate for a premium. In 1777, when Brockelbank died he succeeded him as collector, and when A. M. Bailey resigned, he was appointed registrar. He had wished to offer himself for the post in 1766, but this had not been permitted. His election as registrar took place in May, 1779, at the meeting when Richard Samuel was elected assistant secretary.

Before he entered the Society's service, Cockings had held some small Government appointment in Boston, North America. He is noticed in various biographical dictionaries (including the "Dictionary of National Biography"), on the ground of his having produced certain inferior poems and dramas. Of most of these the present writer is not in a position to offer any opinion, as he has not felt it his duty to study them, but one particular epic, "Arts, Manufactures and Commerce," written in 1766, no doubt in the first flush of satisfaction at being appointed porter, he has sampled, and he can only express a regretful belief that the very contemptuous opinions of the critics of his other works are probably fully justified.* But Cockings was a better official than he was a poet. He worked himself up from a very humble post to a responsible position. In one capacity or another he served the Society well for thirty-seven years, and he evidently gained the esteem and approval of his employers long before his death in February, 1802.

For some years before his death, he had been assisted in his work by his daughter, Ann Birch Cockings, and she was appointed his successor, with the title of housekeeper, but practically with the same duties as her father. This office she held for forty-two years, till her death in February, 1844. She was evidently a very remarkable woman, endowed with great force of character, and it is quite clear that, during the later years of her life, she practically ruled the Society. Tradition records that she had a

* It may be but reasonable to give readers an opportunity of judging for themselves. The following extracts are fair specimens, and are selected because of the courage they show in compelling the muse to treat subjects generally held to be beyond her competence:—

"On Principles of Skill, (well understood,)
With plain intelligible Aptitude,
To polish Glass, a new Machine comes forth,
(Whose future Trials may proclaim its Worth ;)
'Tis work'd by windy Pow'r, or watry Force,
Or by a circumambulating Horse :
Two diff'rent Ways the Crank, the Runner guides,
As o'er a subject Plate it gently glides ;
By other Cranks, some Polishers are made
At first t'advance, and then turn retrograde ;
And as they o'er the Spheres, and Basons pass,
Polish the convex, and the concave Glass."

And again :—

"Efford contrives a Rod, by Rules of Art,
For Mensuration of th' internal Part
Of any Cask, which gives th' exact Contents,
Better than any other Instruments :
Inserted thro' the Bung, compactly shut,
And thro' the Liquid perpendic'lar put,
By an expanding Pow'r, 'tis open thrown,
Both Bung, and Length, at once are truly shown."

Hosted by Google

bitter tongue as well as a strong will, and the story already told of her* may serve to show the view she took of her own duties, and of her relation to the other officials of the Society. She became eventually, in name as well as in fact, registrar and librarian, as well as housekeeper, and if she never assumed the title of secretary, she probably did her share even of the secretary's work. Apparently a truculent and masterful old lady, she was an earnest and devoted servant, who was appreciated and esteemed by the masters whom she ruled. When she died, they subscribed for a monument in Kensal Green "in grateful remembrance of the perfect integrity and the constant and zealous diligence with which she performed the duties of her office."†

Aikin was certainly the most accomplished secretary the Society had had since the death of Templeman, but this did not prevent the Society's decline during the term of his office. This is not to say that he was in any way to blame for the result, and indeed it appears from what has been said above that he realised that the time had come for a change in the Society's methods, and he did his best to initiate such a change. There is good authority for saying that he in later life stated to his brother and his nephew that he could never get his ideas properly supported by the influential members of the Society, and the history of the years immediately following his resignation renders the accuracy of such a statement not only probable but obvious. It is very likely that he was not specially endowed with those qualities which go to make a good man of business, but he was a man of refined and cultivated intelligence, who had also the gift of making himself liked by those with whom he had to work. Still the fact remains that at the end of his secretaryship the influence and reputation of the Society had reached a very low point. Its resources had fallen off and the number of its supporters had seriously diminished. As a matter of fact, the Society's revenues had been for some years decreasing. Its period of greatest prosperity was in the first ten years of its existence. The largest amount subscribed in any one year was in 1763, when a sum of £4,614 was collected. In succeeding years we find a gradual falling off, till at the end of the century the average income was about £2,000. In 1804 a careful examination was made into the Society's financial condition, and an analysis of receipts and expenditure for the seven years ending with 1803 is given in one of the volumes of committee minutes. From this it appears that the annual receipts just balanced the annual expenditure, there being a trifling surplus, about £150, on the results of the seven years' work. At this date about £50,000 had been expended in premiums since the Society's foundation. For the next quarter of a century the income fluctuated about this same figure, with a tendency to decline, and then it began to drop, till we find that the balance-sheet for the year ending June, 1837, shows a total revenue of only £1,235, and a debt of nearly £300. After this things went from bad to worse, until, as we shall see later on, the Society was reorganised, and its affairs again put on a prosperous and satisfactory footing.

The causes for this unfortunate condition of an institution which had for long been so prosperous and so popular were no doubt various. The political and economic state of the country may have contributed. For long after the end of the Napoleonic wars there was serious industrial depression, and this must have reacted on a Society whose main objects were industrial. Also it had to contend with the competition of many similar institutions. By the end of the first half of the nineteenth century there had been founded the Royal Academy, the Linnean, Geological, Chemical, Agricultural and Geographical Societies, the Royal Institution and the London Institution, the Institutions of Civil Engineers and of British Architects —all occupying ground once left to the Royal Society and the Society of Arts. But it is certain that the main factor was the obsolete character alike of the Society's objects and of the manner in which they were carried into effect. Its constitution badly needed reform, and until that reform was effected, as it was a few years later, the Society remained incapable of useful work, and consequently not likely to receive public support.

The idea of encouraging industrial progress by the award of prizes, useful at a time when practical applications of science were unknown, and invention required all the artificial stimulus it could get, was out of date. As the provision of such prizes was obviously ineffective, people were less ready to provide money for them, and so the whole scheme came near collapse. Besides, had the scheme been sound, the manner of its administration was ineffective. The whole business of the Society was carried on in open meetings, which all members had a right to attend, and at which consequently the

Hosted by Google

attendance was always different. The natural result was that the less work there was to do, the more time there was spent in doing it, and the more talk in getting it done.

The consequence was that as there was not much to do, the time was expended in discussing the proper way of doing it, and in making elaborate regulations to that end. The story goes that Lord Brougham, on one occasion attending a meeting of the Society, went off with an outspoken declaration as to what he hoped might be his final fate if he ever wasted his time with a Society that spent all its time in discussing "rules and orders." Thus was lost to the Society the energy afterwards expended in promoting the Society for the Diffusion of Useful Knowledge and the Social Science Association, two institutions which owed much to Lord Brougham's exertions.

To such a serious condition had the Society's affairs come, that at the first meeting of the session 1841–2, the Committee of Accounts reported that it had practically used up all its available resources, that its revenue was insufficient to meet its expenditure, and that of its accumulated funds only some £400 was available to meet future deficiencies. A special committee was at once appointed to consider the position of the Society and to suggest "means by which the Society can be rendered more efficient, both as regards its objects, management, and constitution." The chairman of the committee was Thomas Webster,* and its appointment was the beginning of the much-needed reforms which he, and a small party of which he was the leader, eventually succeeded in bringing about. This committee, which was only appointed on November 17th, produced at the meeting of December 15th an excellent and exhaustive report, one characteristic of which was its extreme candour, and another the clear insight it showed into the causes of the Society's decay. Two passages are worth quotation:—

"Among the causes which have contributed to the present state of the Society, the most prominent appears to be the want of an efficient governing body to direct the general proceedings and the internal regulations, upon the proper control of which the success of every society so much depends.

"From the period when the Society was established to the present time, the system pursued has differed from that of all other societies instituted for the promotion of science and art, in which a council or committee of general management has always been considered essential.

"The want of a superintending council was not for many years perceived or felt. But with the rapidly-spreading taste for useful knowledge and scientific pursuits, other societies arose of a popular character, and the consequences soon became apparent in the diminished funds of this Society, whose great object is the promotion of the useful arts rather than the personal gratification of its members."

* * * *

"Another prominent cause has been the withdrawal of active members from the committees, the consequence of which has been a want of confidence in the decisions and a falling off in the number and value of the reports of the committees. These, and other causes combined, have led to a decline in the interest of the weekly meetings, the proceedings of which are now principally confined to discussions of rule and order, accounts and other matters, not tending to promote the interest of the Society."

After some very judicious remarks on the wide field open to the Society, notwithstanding the competition of newly-instituted societies with more specialised objects, in the application of science to the arts and manufactures, it goes on to suggest the formation of a governing body or council, to consist of the chairmen of the six principal committees, the president, two vice-presidents, and two treasurers. The three other committees would be abolished, their duties being transferred to the council.

Among the various other suggestions made in the report, certainly the most important are that the principal object of the Wednesday evening meetings should be the reading and discussion of communications on the arts and manufactures of the country, and that the exclusion of patented inventions from awards had been "extremely detrimental to the interests of the Society."

However, when this very judicious report was submitted to a general meeting of the Society in the following January (1842) it met with distinct opposition. Eventually most of its proposals were disapproved, and after a good deal of argument, another committee was appointed, which in its turn reported advising a number of economies, the result of which

* Thomas Webster (1810–1875), afterwards Q.C., and an eminent patent lawyer. At this time he had only lately been called to the Bar, after acting for two years (1837–39) as Secretary of the Institution of Civil Engineers. Associated with him in the reform of the Society were Edward Speer, George Bailey, J. Scott Russell (the eminent engineer, afterwards Secretary), John Bethell, Joseph Woods (architect, geologist, and botanist), and William Tooke (solicitor). Thomas Webster's second son, Richard, afterwards became Lord Alverstone, L.C.J., and he has followed his father's example by his devotion to the interests of the Society.

must certainly have been the winding-up of the Society for good and all. One of these suggestions was that there should no longer be a salaried secretary, but that the office should be placed in commission, its duties being discharged by a committee of five members. Graham, the secretary, promptly resigned his office, and things appear to have got into a general muddle. Webster's committee was reappointed, and they prepared a report practically on the same lines as their previous one. This time they took the precaution of submitting it to the President, the Duke of Sussex, who cordially approved it, adopted it as his own, and sent it as such to the general body. It was, of course, accepted without much further demur, and in April, 1843, it was adopted. In the following month a resolution of thanks to Webster was passed, which shows that, in spite of what seems to have been merely factious opposition, the Society appreciated his labours on their behalf. This was the last service rendered by the Duke to the Society, for he died in the following April. It was, however, no trifling one, for it enabled the necessary reforms to be effected, and thus helped to start the Society on a new and prosperous career.

Part of the committee's work was to provide for the immediate carrying on of the regular work of the office. They therefore recommended that a temporary arrangement for filling the office of secretary should be made, and at their request Webster undertook to find a suitable person. He had but lately resigned the office of Secretary of the Institution of Civil Engineers, and was therefore thoroughly familiar with the ordinary routine of a society's work. At a meeting of the Miscellaneous Matters Committee in January, 1843, he produced a letter from Francis Whishaw, an engineer, who was then known principally as the author of a volume published in 1840 on "The Railways of Great Britain and Ireland," in which Whishaw offered to act temporarily as secretary on the terms proposed — two guineas a week, together with the use of certain of the rooms in the secretary's house. This offer was accepted, and Whishaw was appointed. At the annual election in April, 1843, Whishaw's name was placed on the balloting list, and he was duly elected at a salary of £150 a year and a house.

Among other recommendations of the committee was included one to the effect that it was not desirable to continue the office of assistant secretary, and notice was given to Woodfall in March, 1843, that his services would be dispensed with, but that his salary would be paid until the end of the session, and that he would have an additional grant of £100. A very complimentary vote of thanks was also passed to him at the annual meeting, and he was presented with a set of Barry's etchings, a gift which at the time was made by the Society to various people to whom it was desired to pay a compliment. Woodfall at first protested, but eventually expressed himself as entirely satisfied, although he said that it was with very great regret that he gave up a service which he had held for thirty-seven years. He appears to have discharged all his duties efficiently. On several occasions additional grants were made in augmentation of his salary, which was always on a moderate scale.

For some months Whishaw carried on the work without assistance, but in October, 1844, he was authorised to engage somebody to help him, and he engaged S. T. Davenport, then a young man of twenty-one. Davenport developed into a very valuable and trusted official, for he served the Society in various capacities for over thirty years till his death in 1875.

Whishaw held the secretaryship for nearly two years, until November, 1845, when he wrote that he wished to resign, as he had accepted some other work which would prevent his giving proper attention to that of the Society. This work appears to have been an appointment in connection with Prosser's wooden railway.* At the same time he stated that Mr. Scott Russell was willing to undertake the work of secretary, and proposed that he should be nominated jointly with himself. This offer was accepted, and Scott Russell was appointed. At the annual election in the following year, in April, 1846, Scott Russell was elected secretary, Whishaw being elected corresponding secretary. In 1848 he was made auditor, and after this his official connection with the Society terminated; but he had been elected a life member on his resignation of the secretaryship, and he continued

* This was a scheme for the use of wooden rails, which it was thought would be cheaper than rails of iron. The inventor was William Prosser, the Secretary of the Metropolitan Railway Company, who took patents out for his invention in 1843 and 1844. An experimental line was laid down on Wimbledon Common. Although favourably reported on by Major-General Pasley, Inspector-General of Railways, the scheme never came into practical use. Prosser himself did well out of it, for his rights were purchased by the London and South-Western for £20,000. He also received £32,000 from an Irish line. A full account of the system will be found in the *Engineer*, January 5th, 1900, p. 9.

Hosted by Google

to take an interest in the Society's work. The chief thing for which he is to be remembered is that he originated the idea of holding exhibitions, first on a small scale in the Society's rooms, and afterwards in the form of a national exhibition of industries. A full account of this work was given in an article in the *Journal* of November 6th, 1896, dealing with the early history of the 1851 Exhibition, and need not, therefore, be repeated here.

Although both before and after his connection with the Society, Whishaw appears to have been fully occupied in work associated with the construction of railways and of electric telegraphs, his career was, on the whole, not a fortunate one. In later life he seems to have suffered a good deal from illness, and eventually he died in October, 1856, in Marylebone Workhouse.*

The most important reform, however, suggested by Webster's committee was that a council or managing committee should be appointed, which should have full control of the Society's business, thus taking it out of the hands of the general body, and this was really the crux of the whole business. Though the change was greatly disliked by the excellent persons who had found amusement and occupation in the control of the Society's affairs, the reform had been passed, and, in order to carry it into effect, a complete revision of the old rules and orders of the Society was necessary. Such a revision was made, and in December, 1845, new rules and regulations were passed, establishing a managing committee or council, and giving that body the necessary powers. It was to consist of the chairmen of committees, together with a certain number of elected members. The first meeting of the council was held on December 6th, 1845, with Edward Speer in the chair. For the first few months of its existence, the council seems to have had no regular chairman, but after its election at the annual meeting in March, 1846, Edward Speer and George Bailey† were elected chairmen, and this arrangement was repeated in 1847 and 1848.

The council very soon got into active work, and the wisdom of the change became evident. Its proceedings, however, and the many useful alterations it introduced into the work and the character of the Society, will be more fitly considered when we come to deal with the history of the Society after the grant of a Royal Charter, the attainment of which was one of the first matters with which the new council dealt.

It is rather remarkable that no steps had ever before been taken towards making the Society a chartered body, although, as will be remembered, the suggestion that a charter should be applied for was one of the very earliest matters considered. Whether the original proposal contemplated a charter for the Society in its original form, or a charter for an academy of painting and sculpture, is not quite clear, but at all events it was in the latter form that the proposal was submitted to the Society in 1755, and, as previously mentioned, a complete draft of a charter for a Royal Academy of Arts is preserved among Dr. Templeman's papers. It may have been intended that the Society should be merged in such an academy. Probably this idea was not consonant with the notions of the original promoters of the Society, and it was for this reason that it was opposed and dropped, to be resuscitated later on by the committee of artists and successfully carried out in the foundation of the Royal Academy.

The question does not appear to have been brought up again till 1843. In December of that year the secretary (Whishaw) reported to the Committee on Miscellaneous Matters, that "the subject of the Society obtaining a Royal Charter had lately been a matter of conversation by two or three members, who were willing to subscribe £5 5s. each towards this desirable object." But nothing was done. In February, 1845, the question of applying for a Royal Charter was raised at one of the meetings, and was referred to the Committee on Miscellaneous Matters, but no result followed. At last, in February of the following year (1846), the newly-formed council took the matter up seriously, and recommended that steps should be taken to make application for a Royal Charter. In December of the same year we find that a draft of the Charter was submitted by William Tooke, who was then acting as the

* A full biography of Whishaw is given in the *Proceedings of the Institution of Civil Engineers*, Vol. XVI. p. 143. The account of his connection with the Society requires a little modification, for it attributes to Whishaw's efforts rather more importance than is actually their due. It does not mention his unhappy end, about which, however, there is no doubt. It is recorded in Boase's "Modern English Biography" (1901), Vol. III. p. 1306, and in the *Gentleman's Magazine* (November, 1856, p. 642). The facts have also been verified by the Clerk of the Marylebone Board of Guardians, who, at the request of the writer, very kindly made a search in the records of the Marylebone Workhouse.

† George Bailey (1792–1860) was the first Curator of the Soane Museum, having been designated for the post by the founder. He was articled to Sir John Soane, and remained in his service first as architectural assistant, and afterwards as confidential clerk. He became a member of the Society of Arts in 1821, and continued until his death in 1860. After serving, as above mentioned, as one of the two chairmen of Council for three years, he resigned membership of the Council in January, 1849.

Hosted by Google

Society's honorary solicitor. This being approved, in the following March (1847) Tooke brought up a draft of the Charter, together with a petition, which, after they had received the approval of H.R.H. the Prince Consort, as President of the Society, were lodged in the Privy Council Office. In June, Tooke reported that the Charter had been passed, and that fees amounting to £400 in all were required—of these the official charges amounted to £308 9*s.* 2*d.*, and there was about £75 for office expenses.

With the grant of a Royal Charter, the Society entered on a new chapter of its existence, and at this point the record of its older history may fitly be closed.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

The Coal Strike.—Difficulty in obtaining good steam coal was experienced at many textile works some while before the coal strike was declared, and similar difficulty is to be apprehended for some time after peace has been arranged. After the first fortnight of the strike certain Lancashire and Yorkshire mills closed because of the exhaustion of fuel and of inability to pay the high prices demanded by coal holders. Others, by closing on one or two days in the week and paying prices three or four times higher than usual for coal of uncommonly low calorific value, have contrived to hobble along with varying degrees of inconvenience and expense. The specialisation of the industries has the effect of causing some to feel the burden of dear fuel more than others. Spinning mills require relatively more power than weaving mills, and also require the maintenance of a greater atmospheric heat, and again their cost of power is a larger factor in the price received for the goods. Where boiling is done, as in bleaching, dyeing and finishing, large volumes of steam are wanted for the heating of vats, and in a trade like woolcombing there is need both for high power and high heat. Until the introduction of improved stoking and steam economising appliances, steam used often to cost dyers and finishers of wool goods 12 per cent. of the cost of production, and although this has been cut down more than one-third in most quarters, the effect of multiplying this cost by four or five times can readily be appreciated.

Charges of 38*s.* and so a ton for worse fuel than that which normally costs 8*s.* have sharpened the desire for economy. The railway strike of last summer directed the attention of manufacturers to motor transit by road, and the coal strike has impressed men with a sense of the desirability of making changes that have long been recognised as advantageous, but have not been adopted for want of an immediate stimulus. Probably there are in all industries arrangements which would be revised were one starting afresh, and certainly in textile works there are several. In the way of new experiments, devised to meet the emergency, an attempt to use oil fuel may be mentioned. Spraying oil direct upon burning coals set up an intolerable smoke nuisance, and although smoke was avoided by spraying upon fire-brick the costs did not compare favourably at the price then obtaining for oil fuel. The adaptation of boilers designed to burn coal to the burning of liquid fuel appears to require more preparation than can be given at short notice.

Steam remains incomparably the chief form of power used in textile industry, and by reason of its low cost and flexibility is still the favourite. Electricity extends gradually in the weaving departments and in cloth finishing, where work is of a more or less intermittent character, and the direct coupling of motors to the machines permits of certain economies. Where the load is constant, as in the spinning trade, electricity presents most advantage to the tenants of crookedly designed mills. The common calculation is that to compete in price with steam in a "straight line" mill current needs to be raised at ·3*d.* per unit, which is materially less than the ordinary charge for a municipal supply. Suction-gas engines have worked with admirable economy in some weaving sheds, but they are not generally regarded as being as free from the risk of breakdown as the steam engine, and they do not supply heat. A silk-weaving manufacturer finds his separate cost of heating the premises as great as that of driving his looms from a producer-gas engine. For occasional auxiliary power even the water-motor, driven by main pressure, is not wholly unknown in mill use.

The reactions of the coal strike upon the future of industry have been of less concern than the immediate effects upon trade. In satisfaction of existing orders the machines have more or less continuously been turning out goods, but in the home market there has been a paralysis of distribution. On general grounds it may be believed that distributors, both wholesale and retail, have made smaller preparations than last year and carry smaller stocks. The commercial travellers have been off the road since the first week of March in most instances. Drapers in the industrial parts of the country are in contemplation of a ruined Easter trade, and wholesale warehousemen are inclined to expect a hurried demand for supplies relatively late in the season. The expectation leads them to hopes of clearing old stock, and of picking up new goods when wanted rather than to any placing of new orders. Dismal as are the immediate effects of the strike calamity, there are ulterior difficulties within the reach of foresight. Textile materials have hardened rather than softened in price during the disturbed period, but both of cotton and wool there are extraordinarily large supplies.

"Bembergised" Wool.—A process strikingly akin to that which takes its name from John Mercer has been developed on a commercial

Hosted by Google

scale in Germany. Mercer, in 1850, took out his patent covering the action of alkalies upon vegetable fibres, and nearly half a century later mercerised cotton, under its own name and a medley of fancy names, became a conspicuous article in the market. Mercerised cotton took the place of silk for stripes and checks in weaving and for crochet, embroidery, and fancy work. Mercerised cotton handkerchiefs, under one invented name or another, are in all the shops, and mercerised cotton linings have nearly driven out worsted and cotton lining from factories where cheap garments are made. Cotton cloth mercerised, dyed, and schreinerised (*i.e.* pressed between rolls engraved with fine lines) assumes the sheen of silk. The effect is due to a restraint of the change normally caused by immersing cotton in a caustic soda solution. The alkali operates to shrink the cotton, and its contraction is prevented by mechanical tension. Cellular strains are set up within the fibre and the cell walls collapse, so presenting an increased number of surfaces reflecting light. The cotton, if thoroughly neutralised and washed, gains strength, and it acquires an enhanced affinity for dye-stuffs.

The process patented by Elsaesser, and called "bembergising" by those who have developed it, applies to wool instead of to cotton. Worsted yarn of comparatively poor lustre is treated with bisulphite of soda at a high temperature, and the tendency to shrink is counteracted. The treatment is continued until the thread exhibits a stringy, gelatinous elasticity, and ends with boiling in an acid solution and a final washing. Mercerising cotton increases the length to a nominal extent, but "bembergising" stretches out worsted by 33 per cent., reducing it in diameter and also in twist, but not in strength. The lustre is highly enhanced without causing harshness of touch. The departure from the ordinary means of improving the lustre of wool is a marked one. Hitherto the methods in use have been rather physical than chemical, and have consisted chiefly of the use of water, heat and pressure, coupled with methods of removing protruding fibres obstructive of the reflection of light.

Rainproof Cloth.—There is evidence on every hand of the popularity of the raincoat, which has so largely replaced the rubber macintosh. High prices for rubber and too free resort to unsatisfactory rubber substitutes explain the discredit into which the cheap macintosh has fallen. Porosity, cheapness and some other virtues account for the ubiquity of the rubberless rainproof. The cheapest kind of double-fabric waterproofing with rubber and its substitutes is understood to cost 1*s.* 6*d.* a yard; which sum will pay for rainproofing twelve yards. The rain- or shower-proof treatment is not new, and this is not the first burst of popularity the raincoat has enjoyed, but the details may be stated for any interest they possess. Cloth intended for raincoats is treated in continuous machines, which impregnate the fabric thoroughly with acetate of alumina. The chemical, although highly soluble in water, and hence evanescent in its effect, itself markedly improves the original resistance offered by the cloth to the passage of water. Coming out of the series of baths in which the impregnation takes place, the cloth is dried more or less effectually by suction and heat. It thereupon receives a coating of wax, usually compounded of paraffin wax of high melting-point and some harder waxes. According to one system the wax is applied frictionally and dry; in another the wax is melted and applied in an infinitesimally fine film from the face of a small roller. The wax is a separate rainproofing agent, and it helps to lock the soluble chemical within the fibre.

Cotton, silk, linen, and wool are treated substantially in the manner described, and not always for coat-makers. Tent-cloths, awnings, and sail-cloths are sometimes rainproofed; balloon and aeroplane fabrics are 'proofed to prevent the development of mildew from wetting. Even tyre fabrics for motor-cars, and rugs destined to be lined with a rubber film, are first given this upper form of protection. The habit of riding in covered vehicles has reduced the necessity for wearing wind- and watertight overcoats, and the fact has been presumed upon. A dozen years ago the name "rainproof" fell into undeserved disrepute when thousands of pieces of cloth, which had undergone no efficacious rainproofing process, were stamped with the word "rainproof" and sent out to disgust the public. This second or third rise of rubberless rainproofing into general favour is also the highest that has been known, although an end to its popularity was confidently predicted for last year. Something is to be credited to a relative absence of deception, and something to the skilful and spirited advertising of certain tailoring firms. Flexible felt hats treated with acetate of alumina, and rainproof straw hats sprayed with a celluloid varnish, are the new concomitants of the rainproof coat. The hard felt hat is protected by its shellac. The silk hat defies the rainproofer by presenting a pile which lies in the direction of the weft, instead of following the warp as in other plush fabrics, and is consequently not eligible for treatment in his continuous machines.

CORRESPONDENCE.

THE INDIAN CENSUS.

A remark I let fall in the discussion of Mr. Gait's paper seems to have been understood to be a general depreciation of the value of mathematics in census work. I merely wished to point out that for the administration of the operations, *district* experience was the essential qualification, and mathematics only came in at the later stages. The Census Commissioner, for instance, cannot adequately handle his figures unless thus equipped for analysis and co-ordination. J. A. Baines.

NOTES ON BOOKS.

SEA FISHERIES: THEIR TREASURES AND TOILERS. By Marcel A. Hérubel, Doctor in Science and Professor at the Institut Maritime. Translated by Bernard Miall. London: T. Fisher Unwin. 10*s.* 6*d.* net.

"The French mind loves generalisations; it would rather have erroneous generalisations than none at all." This admission on the part of its author suggests at once the strength and the weakness of this book. Of generalisations there are plenty, in fact, too many in it. Most of them are sound; some are premature; others are extremely debateable. Unfortunately, also, there are some considerable inaccuracies in the parts of the book which refer to the North Sea. But although not altogether reliable in regard to certain specific questions, it is certainly the most comprehensive and most luminous book on the subject that has yet appeared. Written chiefly in the interests of the French industry, it deals with all sea-fishery problems of vital importance to European nations in general and to Britain in particular; the supremacy of our country in regard to sea-fisheries being still unquestionable, although it is somewhat disquieting to read that "for one step taken by the French, the English take fifty and the Germans a hundred!" All the more reason why some of us should take the subject seriously to heart and try to understand it.

In the first section of the book the results of oceanographical and marine biological research are rendered intelligible to non-specialists and brought into touch with the realities of fishermen's lives. The bearing of a scientific knowledge of the sea on the important questions of depopulation and repopulation of the fishing grounds, is clearly shown. We are still far from anything like a complete and concise expression of natural law in the marine world. Instead of comprehensive formulæ we have a number of incompletely coordinated facts and ingenious hypotheses, which may or may not turn out to be correct theories. Any attempt, then, at a synthesis in the present state of our knowledge implies a good deal of premature generalising, as when the author speaks of several races of herring and plaice in the North Sea. We do, however, already know a certain amount regarding the biology of certain important fishes, their habits, their reproductive powers, their spawning grounds, their ages and rates of growth. We can, in the case of a few fishes, distinguish with a fair degree of probable accuracy spawning migrations and feeding migrations, and we know something as to the extent, direction, and rate of their movements. We also know a good deal about the chemistry of production in the sea; about the qualitative and quantitative distribution of the "plankton," that heterogeneous congeries of generally minute and often microscopic plants and animals which float in the upper layers of the sea and are present everywhere; about the seasonal changes in that part of the Gulf Stream circulation which affects and profoundly influences the fisheries as well as the climate of Western Europe. We know a good deal but not nearly enough about these things. We probably know enough, however, to justify Professor Hérubel in most of his generalisations and to support, for instance, his definition of fishing-grounds as "regions in unstable equilibrium, where there is an encounter of two critical conditions, one biological and the other oceanic."

When, however, it comes to applying this incomplete scientific knowledge of the sea to the practical solution of the problems of depopulation and repopulation, generalising, to the extent to which Professor Hérubel indulges in it, becomes a rather precarious pastime. One can agree in a tentative way with some of his conclusions, such as the following: "As for herring, cod, mackerel, sardines, sprats, and whiting, take them when and where they may be found; but give soles, turbot, and brill* the time to grow. They will never go far from the shore; you can always find them again." The second part of this statement is sound, but one cannot be *quite* certain that the first is. Again, while one is quite prepared to believe in the local utility of artificial coastal reservoirs for sea-fish such as are to be found on the coast of Brittany, in the fish-ponds of Arcachon and the lagoons of Venice and Commacchio, it is another matter if we are asked to share the author's evident, though not, it is true, definitely expressed, sympathy with the wholesale closure of inshore areas such as the Moray Firth.

But Professor Hérubel is on still more dangerous and dubious ground when he maintains that the small inshore or longshore fisherman is "the chief sinner" as regards the destruction of immature flat fishes. Evidently the Professor is insufficiently acquainted with the plaice fishery in the North Sea and with the data which have been published regarding it, or he would not have made this—so far as the small fisherman is concerned—damaging statement; for it is almost certainly the steam trawler in the offing, whose efficiency Professor Hérubel admires so much, that does most damage, since it captures the immature plaice just at the period when they are increasing most rapidly in market value. How the case stands in regard to soles and turbot is at any rate a matter on which it is only fair to suspend judgment, for the evidence merely of large *numbers* of small fry being destroyed largely misses the point. There is, however, another and more general way of regarding the question. The inshore fisherman on a small scale has been with us for centuries; in fact until comparatively recently—in the historical sense—he was the *only* kind of fisherman. But at the time when trawling on a big scale commenced in the North Sea, about the middle of last century, the fishing grounds were thick with large plaice, and "fortunes" were made by the discovery of great accumulations of soles in certain parts of the North Sea. Such

* Why not plaice?—Reviewer.

Hosted by Google

fortunes are impossible to-day; the "accumulated stock" has long been fished out, and signs of an "overfishing" of the "current stock" have appeared in a decrease in the *average size* of plaice on the fishing grounds and in a general scarcity of soles. It is difficult to see how the small fisherman figures as "the chief sinner" in this description of the historical course of events.

Several errors in statements of fact have crept into the passages in this section which refer to the North Sea. Thus it is erroneously stated (table, p. 47) that the plaice spawns in May and June; and the flounder is classed with sturgeon and salmon as a fish which seeks rivers in which to spawn (footnote, p. 25). In another footnote (p. 24) some remarks on the distribution of the younger and older stages of the sole are stated to "apply to all flat fishes," which they certainly do not. They do not apply, for example, to that important flat-fish, the plaice. Again, Professor Hérubel is quite in error in maintaining that the catch per diem of plaice in the North Sea has steadily decreased during the last few years. His comparison of two selected years, 1903 and 1906, is obviously quite inadequate in this connection. The author's account of Professor Garstang's transplantation experiments is also misleading. He quotes M. Cligny to the effect that "the plaice taken from the Danish coast and transplanted to the Dogger seem to have grown normally, despite the length of transport." What actually occurred, as described in an English blue book, was that the fishes transplanted from the Danish coast to the "Tail End" of the Dogger grew normally, but those transplanted from the same coast to the "Shoal" of the Dogger underwent an abnormal increase equal to that exhibited by plaice transplanted to the same part of the Dogger from Bridlington Bay.

It is especially in this section that one notices not a few samples of singularly unhappy rendering into English of words and phrases. Thus Professor Hérubel is made to speak of the "emptying of the North Sea," when what he means is the progressive and rapid depopulation of that sea. Obviously "empty" is employed in the wrong sense here, apart from the exaggeration of the underlying thought. In another place we read that an "explanation is too systematic to be complete." Evidently "systematic" is not the right word. Neither are "azote" (for nitrogen), "anfractuous," and "enounce" current coin of language. These defects in the translation and errors in the original ought not to have been allowed to survive the final proof-reading, and their publication might easily have been avoided had the proofs of the book been consigned for revision to some competent English expert on sea-fishery matters, possessing a knowledge of the North Sea and, incidentally, of what constitutes good English as well.

The second section of the book deals with the sea-fisheries of France in particular and Europe in general from the standpoint of production. In this part of the book Professor Hérubel goes carefully and critically into all the principal questions relating to boats, fishermen, and fishing ports; into all the machinery of production and the details of organisation; into the relations of capital and labour, total production, and distribution of profits. He displays the inferiority, the relatively unprogressive character of the French industry as compared with that of Britain, Germany and other European countries. In the following striking passage the relative positions of France and Britain are very concisely stated:—

"The number of sea-going fishermen in France is about 100,000. Great Britain possesses about the same number. There is also in France a population of some 60,000 ashore—men, women, and children—actively engaged in the fishing industry. If we take the average figures of the season's fishery in France—namely, 191,600 tons of fish, and £4,400,000—we find that each fisherman is responsible for an average of two tons of fish, each ton being worth about £22 16*s*. The profit per man, in round figures, is £46. The English fisherman produces considerably more. The total average catch amounts to 958,000 tons, worth £10,120,000. In other words, the English fisherman is responsible for an average annual catch of 9·58 tons of fish, each ton being worth about £10 11*s*. 2½*d*., so that the yield per man is roughly £101 per annum. In other words, the British fisherman catches nearly five times as much as the French fisherman, and, although he sells it at less than half price, he gains more than twice as much as the French fisherman. As, like all industries, and all branches of organised commerce, fishery is one of the forms of the universal striving for gold to assure the worker of food and drink, we may assert that the economic inferiority of the French fisherman arises from the defective organisation of the French fisheries. The sea belongs to everyone; it is not enough to know it, to be reared by generations of sea-going ancestors, to be cradled within sound of the sea, and lulled by the murmur of its waves; the sea must be exploited as though it were a meadow, a field, a coal-pit, or a mine. Nature does not give; she sells."

What is wrong with the French industry, according to Professor Hérubel, is that there are too many small fishermen and too many small ports; too many sailing boats, and too few steamers and motor craft; the fishermen are not enterprising and educated enough; the State administration, like the boats, is antiquated and effete; and the toll of the middleman and the Customs dues are out of all proportion to the gains of the fisherman. "I would represent the French fisherman as struggling with two men who are trying to strangle him, while a third strews impediments in his path. The two first are easy to recognise—the *octroi* and the middleman—and the third is the railway." Though the metaphor is, perhaps, a trifle mixed it is vivid enough.

The model which Professor Hérubel holds up for the imitation of the French industry is the

Hosted by Google

British industry, and especially the steam-trawling industry as carried on, for example, at Grimsby. For the businesslike way in which Grimsby disposes of fish our author has unbounded admiration. He apparently thinks that the mere inshore fisherman is a poor creature compared with a member of a crew of a steam-trawler. Whatever the conditions may be in France, there is surely something in this country to be said for the inshore fisherman. For one thing he is less specialised and, therefore, a more complete and healthy character than the steam-trawlersman. It is scarcely conceivable that the best interests of the nation would be served by the suppression (Professor Hérubel does not indicate how this is to be brought about) of a set of men who possess such pleasant traits of character as do our longshore fishermen; traits of character which it is a matter of common knowledge are not possessed in anything like the same degree by the average steam-trawlersman. Professor Hérubel is so rapt in admiration for the industrial efficiency of Grimsby, that he does not mention the other side of this flourishing port; its ugliness, its mean streets, and sordidness. If one would look at the question from the broad human standpoint, and not merely in the cold light of scientific admiration for industrial efficiency, this other side of the question must be taken into account. Anyone who has compared Grimsby with, say, Flamborough, Aldeburgh, or Sidmouth from this standpoint, will appreciate the force of this criticism. The ultimate disappearance of the fishing village may be inevitable, in many cases it is an accomplished fact; but it is none the less deplorable in the opinion of those who prefer to think of men, however poor, leading healthy lives in pleasant places. If, as has been already suggested, he does not do the damage with which Professor Hérubel credits him, is there any valid reason why the protection of the inshore fisherman should not go hand in hand with the development of steam-fishing on the large scale? Whatever the ultimate solution of this problem may be, there can be no doubt that this and similar questions are of vital interest to a nation whose 100,000 fishermen place over £10,000,000 worth of fish on the markets every year.

In spite of the inevitable human interest attaching to everything connected with the sea, with the lives of the fishermen on it and of the fishes in it, to write a really interesting and readable book on a subject so replete with facts and figures as sea-fisheries; to write with equal facility and understanding on such diverse and apparently unconnected subjects as, for example, marine biology and maritime insurance societies, is an achievement which implies, amongst other qualities, a comprehensive grasp of the whole situation and uncommon powers of generalisation and of exposition. This, however, is what Professor Hérubel has done. He has put an extraordinary amount of life into this mass of facts and figures, and has written an almost brilliant, although not infallible, work, WILLIAM WALLACE.

GENERAL NOTES.

INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.—Progress has been made in arranging the programme of the Eighth International Congress of Applied Chemistry, which will be held from September 4th to 13th, 1912, the opening meeting being at Washington, and the other meetings, business and scientific, in New York. The University of Columbia has placed at the disposal of the Congress whatever of its rooms and buildings may be required for the business of the meeting, while other accommodation will be provided by the College of the City of New York. The announcement contains provisional lists of the cities and industries that may be visited, rules for the presentation and publication of papers, particulars of steamship accommodation, rates, etc. Particulars and tickets of membership may be obtained from Professor M. O. Forster, Treasurer of the British Organising Committee, 84, Cornwall Gardens, London, S.W.

NATIONAL COMPETITION, 1911.—The report of the Board of Education on the National Competition has been issued. In all 13,153 works were submitted from 349 schools and classes. Of these 12,554 came from centres in England and Wales, 56 from Scotland, 489 from Ireland, 9 from Jersey, and 45 from New Zealand. In a large majority of the classes the examiners report very favourably on the work submitted. Ten gold medals, 102 silver medals, 261 bronze medals, 560 book prizes, and 991 commendations were awarded.

MEETINGS FOR THE ENSUING WEEK.

WEDNESDAY, APRIL 10...Automobile Engineers, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. Professor Morgan, "Paraffin as a Fuel."

THURSDAY, APRIL 11...Architects, Society of, 28, Bedford-square, 8 p.m. Discussion on "The Ethics of Architectural Practice."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 8 p.m.

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. C. A. Mitchell, "The Scientific Examination of Documents."

Automobile Engineers, 13, Queen Anne's Gate, S.W., 8 p.m. (Graduates' Section.) Mr. E. D. Suggate, "Lubricating Oil."

Mathematical, 22, Albemarle-street, W., 5.30 p.m.

FRIDAY, APRIL 12...Malacological, in the Rooms of the Linnean Society, Burlington House, W., 8 p.m. 1. Mr. A. J. Jukes-Browne, "The Genus *Dosinia* and its Subdivisions." 2. Mr. E. A. Smith, "On the Generic Name to be Applied to the *Venus Islandica Linn.*" 3. Mr. Henry Suter, "Note on *Lapparia Parki.*" 4. Mr. H. B. Preston, "Characters of Three New Species of Freshwater Shells from Uruguay. New Species of *Limicolaria* from British East Africa."

British Foundrymen's Association (London District), Cannon Street Hotel, E.C., 8 p.m. Mr. G. Hailstone, "The Application of the Microscope in the Foundry."

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,099. VOL. LX.

FRIDAY, APRIL 12, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

NEXT WEEK.

WEDNESDAY, APRIL 17th, 8 p.m. (Ordinary Meeting.) JOHN HENRY COSTE, F.I.C., "Municipal Chemistry." DR. RUDOLPH MESSEL, F.C.S., President of the Society of Chemical Industry, will preside.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A meeting of the Colonial Section was held on Tuesday, March 26th, 1912; EARL BRASSEY, G.C.B., in the chair.

THE CHAIRMAN said he felt the deepest interest in the subject with which the author was about to deal, and that interest was all the more keen because he had himself been a traveller in Borneo. It was a full credential in Mr. Lovegrove's favour that he was in the service of the North Borneo Company, that he had been in their service for thirteen years, and that he was one of the treasurers of the local administration. To say that was to give the meeting an assurance that Mr. Lovegrove thoroughly knew the country, and that he was able to give information which was certain to be of the deepest interest.

The paper read was—

BRITISH NORTH BORNEO.

By LEONARD LOVEGROVE.

British North Borneo is the northern part of the island of Borneo, and is owned and administered by the Chartered Company of British North Borneo, known here as the British North Borneo Company, and in the Far East as the British North Borneo Government. The boundaries conterminous with Brunei and Sarawak have been delimited. The sea boundary contiguous to Dutch Borneo has also been settled by means of beacons. The inland boundary has as yet only been fixed by latitude, but I hope and expect that it will be marked out very soon. At present the District Officer of Rundum very often is not certain whether he is in our territory or in Dutch Borneo when he is travelling about his district. Our nearest inland police-station to the boundary is Sibungo, and difficulty is experienced in punishing head-hunters and other evil-doers when one is not certain whether they are British or Dutch subjects. Moreover, some of our jungle produce finds its way into Dutch Borneo by rivers which flow into the sea in Dutch territory, and have their source in ours.

HISTORY.

It appears that in the early days the British nearly missed obtaining any foothold in Borneo, but an outbreak of war in Java caused Borneo to be more or less neglected by the Dutch for a considerable period, no effective check being imposed upon the natives with a view to stopping piracy, and the position daily becoming more and more unendurable. On the rise of Singapore direct trade had been established with Sarawak and Brunei, and it became a matter of moment to British merchants that this traffic should be conducted in safety. In 1838 Sir James Brooke, whose attention had been turned to the state of affairs in the Eastern Archipelago, set out for Borneo, determined, if possible, to remedy things. By 1841 he had obtained from the Sultan of Brunei the grant of supreme authority over Sarawak, in which State, on the Sultan's behalf, he had waged a successful war, and before many years had elapsed he had, with the aid of the British Government, succeeded in suppressing piracy. The island of Labuan was occupied by the British as a Crown colony in 1848, and this may be taken as the starting point of renewed British relations with that portion of Northern Borneo to the north of Brunei. In 1872 the Labuan Trading Company were

Hosted by Google

established at Sandakan. They imported a few Chinese, but did not prosper very much. As long as the money was remitted the agent there was able to carry on. After they retired their rights were transferred to a small syndicate, including Lord Redesdale and one or two others, and two or three years afterwards re-transferred to Mr. (now Sir) Alfred Dent and Mr. E. Dent, who sent out Baron von Overbeck to enter into further treaties with the Sultans, with the assistance of the late Mr. W. C. Cowie. Three officers were despatched—Mr. Pryer, Mr. Pretyman, and Mr. Leicester. They were there all alone amongst the natives, and it is very interesting to read their original letters. The natives were very glad to see them. They had been accustomed to be robbed by the chiefs, and they were made slaves; but all that soon changed. After this application was made to the Government for a Charter. There was a long delay over that. Lord Salisbury's Government looked favourably on the matter, but meanwhile they went out of office. Then Mr. Gladstone's Government came in, and after about four years a Charter was given. A small Provisional Association was formed with the assistance of Sir Richard Martin, Sir Rutherford Alcock and others. The Charter was finally given in 1881. The British North Borneo Company was formed in May, 1882, and proceeded under its Charter to organise the administration of the territory. The Company subsequently acquired further sovereign and territorial rights from the Sultan of Brunei and his chiefs in addition to those already obtained; and to-day there are no independent rivers or districts in our territory. The independent rivers were a source of trouble to us, as the people evaded our customs duties, and we were glad, for many reasons, when they were all acquired. In 1888, under an agreement between Her late Majesty's Government and the Company, the territory became a British Protectorate, but its administration remained entirely in the hands of the Company. The Crown, however, controls the foreign relations of the State, and the appointment of its Governors requires the formal sanction of the Secretary of State for the Colonies. In 1890 the British Government placed Labuan under the administration of the Company, the Governor of the State of North Borneo thereafter holding a Royal commission as Governor of that colony, in addition to his commission from the Company. This arrangement held good until the beginning of 1906, when Labuan was attached to the colony of the Straits Settlements.

The total area of the Company's territory is estimated at about 31,000 square miles, with a coast line of over 900 miles. The greater portion is exceedingly hilly, in parts mountainous, and the interior consists almost entirely of highlands, with here and there open valleys and plateaux of fifty to sixty square miles in extent. On the west coast the mountain range runs parallel with the seashore at a distance from it of about fifteen miles. Of this range the central feature is Kinabalu, which is composed of granite and igneous rocks, and attains to a height of 13,698 feet. Three ascents of this mountain were made during 1910. One of these ascents was made by Miss Gibbs, accompanied by Mr. Maxwell, district officer, the chief object being botanical research; another was by Dr. Fosworthy, who, I believe, is an American. The third ascent was made by a scientific party, consisting of Captain Learmonth and Lieutenant Harvey, of H.M.S. "Merlin" (one of the ships which have been surveying all round the bays and harbours of the territory), Mr. R. W. Clarke, of the British Borneo Exploration Company, Mr. Scott-Browne, and Mr. H. W. L. Bunbury, district officer. They had a most interesting trip, although the summit was covered by a mist many of the days they spent on the mountain. They were able to establish communication by heliograph with Jesselton, on the coast. It is impossible to sleep at the very top, there being no suitable place, so the highest camp is a cave, from which day ascents to the pinnacles can be made. Mount Kinabalu is quite one of the sights of British North Borneo. To be seen to advantage it should be viewed from the west at dawn of day, and watched until it is wrapped in the vapour drawn up from the lower grounds as the sun gains power. I have seen it very clearly about 5.30 p.m. from Jesselton without any mist overhanging it. Mount Madalon, some fifteen or twenty miles to the north, is 5,000 feet in height, and inland across the Pagalan Valley, which runs through the Tambunan country, and falls into the Padas River, rises the peak of Trus Madi, estimated to be 11,000 feet above sea-level. The valley of the Pagalan is itself for the most part from 1,000 to 2,000 feet above the sea, forming a string of small plateaux marking the sites of former lakes. From the base of Trus Madi to the eastern coast the country consists of huddled hills broken here and there by regions of a more mountainous character. The principal plateaux are in the Tambunan and Kaningau valleys in the basin of

the Pagalan, and the Ranau plain, to the eastward of the base of Kinabalu. Plateaux of minor importance are to be found dotted about the interior. The proximity of the mountain range to the seashore causes most of the rivers in the west to be rapid and impeded by boulders. The Padas is navigable for light-draught steam launches and native boats for a distance of nearly fifty miles from its mouth, and smaller craft can be punted up as far as Rayoh, some fifteen miles further; but at this point its bed is obstructed by impassable falls and rapids extending to Tenom, where the water is smooth. As the railway runs from Beaufort to Tenom alongside the river, the latter is very little used nowadays. The railway has opened up the interior to the planters, and two European companies are operating in the vicinity of Tenom. There is room for more. The Kinabatangan is the largest and most important river in the territory, and its source is believed to rise eastward of the range of which Trus Madi is the principal feature. It is navigable by steamer for a considerable distance and by native boats for over 100 miles from its mouth. Valuable tobacco land, which, however, is somewhat liable to flood, and remarkable burial caves are found in the valley of the Kinabatangan. Several of the natural harbours of North Borneo are accessible, safe and commodious. Sandakan harbour, on the north-east coast, runs inland for some seventeen miles, with a very irregular outline, broken by the mouths of numerous creeks and streams. The mouth, only two miles across, is split into two channels by the little high bluff-like island of Barhala. The depth in the main entrance varies. I am afraid that there is not much over five fathoms anywhere on the bar. Silting has been going on by degrees, and this is now receiving the serious attention of the Court of Directors.

Sandakan is the capital of the State, although Jesselton, the first port of call on the west coast, is now nearly as important. Lahat Dato, on the east coast, is the headquarters of the Residency, which includes the country south to the Dutch boundary. Kudat, in Maruda Bay, first surveyed in 1881, was the original capital. There is a useful harbour here, and across the bay at Timbang Batu is water deep enough to take the whole Navy.

Revenue and Trade.

The revenue in 1900 was $587,227, in 1905 $994,330, and in 1910 $1,238,505, from which it will be seen that good progress has been made. These figures are exclusive of land sold and price paid for concessions of land. The chief items of revenue are the customs and the monopoly for the excise farms, which are run by a Chinese syndicate under the laws of the Government, a fixed sum being paid monthly by the syndicate to the Government.

The railway receipts in 1909 were $93,756; and in 1910 they had risen to $116,515, a very satisfactory increase. The value of the imports in 1900 was $3,178,929, in 1905 $2,836,676, and in 1910 $3,801,306. The exports in 1900 amounted to $3,326,621, in 1905 to $4,537,486, and in 1910 to $4,609,021.

As will be seen, our exports exceed our imports, which, of course, means prosperity. Included in the imports of 1910 are aerated waters. In future these will show a decrease, as we are starting aerated water manufactories. Cloth will always be a large item, the natives being ready buyers. Ironware and machinery are required by the estates and others. Opium is consumed by some of the Chinese.

Products, etc.

It is a pity that we have to import so much rice that might be grown in the country. Perhaps some day a wealthy Chinese Towkay or merchant will take the matter up; at present the natives plant only sufficient for themselves and a little over. The export of rice and paddy in 1910 was $13,253—probably mostly paddy. Coal of the value of $153,810 was exported in 1910. This is being worked by the Cowie Harbour Coal Mines, who have a storage at Sandakan also.

Cutch or catechu is a name common to several astringent extracts prepared from the wood, bark, and fruits of various plants. It is used as a dye, and most of it is shipped to New York.

Birds' nests are made by a small swiftlet, which selects caves, the larger and darker the better, for building in. The most valuable of these caves occur in limestone rocks. The nests are of two classes—white, and inferior or black. They are collected twice, and in some cases three times a year. The price given for the nests is very high, as they are a great delicacy in China for making soup. Natives who have a share in the caves rarely do any other work for that year, as they can always secure an advance of food and goods from the Chinese purchasers. The share is held in turn for a year by branches of a family, and is often the subject of litigation.

Hosted by Google

Above the mangrove, and where the water begins to be brackish, nipa palms commence, and large swamps of them intervene between the mangroves and true land. From this nipa palm attaps are made for the roofs of houses. The estates use an enormous quantity for their coolies' quarters and drying sheds. Our export is not large, nearly all that is made being bought up immediately. Kadjan mats, also manufactured out of nipa leaves, are indispensable for travelling purposes, as they can be packed up in the smallest compass when not required. Each is capable of affording sufficient cover at night for two or three people, either in boat or forest journeys. They are also used for side-walls and partitions within cheaply built and native houses. The young nipa leaf, unfolded and dried, forms the favourite covering for cigarettes in preference to paper. Copra is the dry kernel of the cocoanut. It is in steady demand for the purposes of oil-making, etc. The refuse of the kernel, after the oil has been extracted, is used as manure, and as food for cattle and pigs; the husk yields coir for rope and mat-making.

Our export of coffee is very small, hardly anyone planting it at all, as it cannot compete with Brazil and other countries. This is to be regretted, for the Borneo-grown coffee is very good, as I am sure everyone will agree who has drunk it at the annual North Borneo dinner in London. Dried fish always finds a ready market, especially now with the plantation coolies. It is a good substitute for the fresh article, which is not always obtainable.

The india-rubber industry received an impetus in 1910, the quantity exported being 54,631 lbs. Sekong Estate accounts for 49,000 lbs. of this. The figures will show an enormous difference in the next few years. The Sekong Rubber Co., Ltd., realised 12*s*. 8*d*. per lb. for its rubber. This was the highest price at one time obtained. At later sales Borneo has again realised almost top prices. We lay great store by our rubber estates.

The rattan is the stem of a creeping prickly palm. The rattan saga is the ordinary rattan of commerce, but there are several others of more or less value known to the natives under various names. Other rattans there are which are utilised as umbrella handles, walking sticks, etc., and very handsome sticks they make.

The sago palm is of two kinds—one the spineless variety and the other the trunk of which is armed with long and strong spikes, which tend to preserve it when young from the attacks of the wild pig, which abound in all parts of Borneo. The palm attains a height of from 20 ft. to 50 ft., and grows in vast forests in swampy land along the banks of rivers not far from the coast.

What is known in Europe as sago is obtained in the shape of a fine white flour from the heart of the palm in the following manner: Just before the terminal spike of flowers appears, about six to eight years from the time of planting, the palm is cut down at the root, divided into lengths to suit the manipulator, and each length split in two, when the pith is scooped out by means of bamboo hatchets, a thin outside skin or rind being all that is left. The pith is placed on mats over a trough by the riverside, and water being constantly poured over it, is trodden out by the natives. A rough separation of the starchy from the woody matter is thus effected, the former running off with the water into the trough below, while the latter remains on the mat, and is thrown away or used as food for pigs. The sago, known then as Lamunta (raw) is sold to the Chinese, by whom it undergoes further cleaning by means of frequent handworking in troughs, and is then packed in gunny bags and exported to Singapore. There it is either converted into the pearl sago sold in the shops, or is sent direct to Europe as flour for use in sizing cloth, manufacture of beer, preparation of confectionery, etc. A full-grown tree is said to produce 200 lbs. to 300 lbs. of sago flour. This sago flour, boiled into a paste, is largely used as food in the place of rice in districts where it flourishes; in fact, I know some natives who prefer the sago to rice. On the other hand, many would rather have rice, but are unable to buy it, and are apparently too lazy to grow it when they have their sago just outside their door. If the palm is allowed to flower and seed, the pith of the centre is found to be dried up and useless, and the tree dies. The seeds are often unproductive, but each palm gives out numerous offshoots, which take the place of the parent tree, and in time leave a family of offshoots, so that a sago plantation once started practically "goes on for ever." Sago grows vigorously everywhere in suitable damp localities. The Padas River has many valuable sago plantations on both banks right up to Beaufort. In 1910 sago, like rice, suffered from lack of attention, a large number of workers having sought employment on estates. The life on the Estates seems to be much appreciated by some, affording, as it does, constant employment,

Hosted by Google

decent pay, and regular hours. Certainly many are distinctly improved after a period of such work.

The timber trade of North Borneo has undoubtedly been very beneficial to the country. We have immense forests, which led to a trade with China, where they grow no timber at all practically. Two steamers are running regularly between Sandakan and Hong-Kong, taking away full cargoes of timber, including firewood. One steamer calls at Kudat and one at Tawao, on the south-east coast, when there is sufficient inducement. Most of the concessions taken up are on the east coast, where the more valuable forests are situated and where the timber is more easily worked, being near the mouths of rivers. There is good wood on the railway line between Beaufort and Tenom, but it has not yet been worked, except in small quantities for use on the railway. There were 159,965 more cubic feet shipped in 1910 than in 1909, and sawn wood is being exported to European ports by nearly every steamer for transhipment at Singapore. Some new Chinese firms are embarking in the enterprise of timber-cutting, and existing concerns are extending their operations. There are two sawmills under European management at Sandakan, and both are working to their full limit. The arrival of the rubber planters on the west coast was a great boon to the mills, as planks are always required on plantations.

Trepangs — a sort of sea-cucumber — are collected by the Bajaus or sea gipsies, who cure and dry them, and bring them to market. They are bought by Chinese traders, and sent ultimately to China, where they are much appreciated, being used to make soup. They vary considerably in price. Some, indeed, have no value at all, and go uncollected; others fetch as much as $25 a picul (133⅓ lbs.), but the usual price is from $10 to $15 a picul. Along the coast they are rather extensively collected; but amongst the islands and on the coast line down to the south there are immense quantities left untouched from year to year.

Rubber and tobacco are now the chief products, but there are signs of an awakened interest in cocoanuts. Para rubber is still the favourite kind, only a very few acres being devoted to other varieties. The system of clean weeding has been generally adopted in preference to the use of catch crops and weed-killers, except in the interior, where passiflora has been found successful. No serious outbreak of disease has been reported, although it exists in some fields. The managers, by treating those trees affected quickly, are usually able to restrict the area attacked. Work was started on seven new estates on the west coast during 1910. In all, at the end of 1910 there were twenty-nine estates planting rubber or tobacco or both.

Five estates confine their attention to cocoanuts, and one to pepper and gambier.

Tobacco was planted on twelve estates in 1910. The crop, on the whole, was reported as satisfactory. A total of 14,819 bales was exported, as against 15,672 bales in 1909. These figures for two consecutive years vary relatively according to whether part of a crop is shipped in December or January. The Sumatra leaf is rather finer than the Borneo one, owing, I am told, to the planters accommodating themselves to the American buyers. Of the finer leaf, weighing less, more can be imported into the United States under the Customs duty. The Borneo leaf, like that of Sumatra, is used chiefly as a wrapper, although pure Borneo cigars are on the market. The Borneo cigar, I am glad to say, is getting more and more into favour with the public, as the price is not exorbitant. On the east coast the seasons are more clearly defined, the wet season being from October or November until March or April. In and around Labat Dato on this coast are situated the concessions of the New Darvel Bay Tobacco Plantations, Ltd., who are usually able to make a very fair profit on their crops. Planting takes place in April or May, and in seventy days the leaves are gathered, so that three months only elapse from the time the seeds are put in the nursery beds until the gathering of the harvest. After the leaves are gathered they have to be hung in drying sheds, and thereafter they are placed in the fermenting sheds and baled for the steamer. The sales take place in Amsterdam by auction. The fields, about 1⅓ acre, are given out to what is called a field coolie, who is working under the advance system—that is to say, everything he takes in the shape of food or cash, etc., is charged to him. His crop is then taken over, and he is credited with the amount, so that he is always working for his own benefit, and this always appeals to a Chinaman. A good field coolie will often clear a net profit of $120—say £14, or even more.

Whilst on the subject of these plantations, I should like to say how much the directors and shareholders are indebted to their European staffs, from the managers downwards. It is impossible to give you an idea of the amount of work got through each day on a plantation, but I can assure you that it spells hard work for everyone. The tobacco companies work on

commission on a schedule to their European staff, which is a good plan, and an incentive to them all. No doubt the rubber companies will eventually adopt the same system.

Cocoanuts are steadily increasing. The cultivation is principally at present on the east coast. The export of copra in 1910 was nearly double that of 1909. The cocoanut palm flourishes everywhere in this region, inland as well as on the seashore, which is somewhat strange, as in many places there is a theory that sea air is a necessity for it. In the Philippine Islands groves of countless thousands exist far inland, bearing heavily and looking extremely healthy. The trees in North Borneo bear fruit much earlier than in most other countries, thanks to the suitability of soil and climate. A considerable number of trees in a grove should be beginning to bear at from four to five years of age.

As regards cotton, I quote from the speech of the Vice-Chairman of the company at the July 1910 meeting :—"The experimental stage of planting cotton, which has been carried on for some years, is now practically at an end. It has been abundantly proved that the soil and climate are admirably adapted to its cultivation, and samples sent to Hong-Kong and Japanese markets were favourably reported on. An estate for the cultivation of cotton would probably prove a financial success if operations were started in one of the more populous districts, where the labour of women and children for picking would be easily obtainable. It is a kind of cultivation that commends itself to the native mind, for it produces good results with the minimum expenditure of labour."

The growing of vegetables and fruit has received an enormous stimulus by the opening up of the new estates, and many fresh allotments have been taken up. The vegetable gardeners are chiefly Hakkas, whose wives all take their fair share in the daily duties. Breeding of pigs usually goes along with the vegetable and fruit garden, and pork is always saleable at a good price. All the vegetable gardeners, native and Chinese, are, I believe, doing very well.

The British Borneo Exploration Company have the sole right of mining granted them under certain conditions. Efforts have lately been confined to the copper pyrites on the Labuk River. This Company have their own geologist. Gold has been found in alluvial deposits on the banks of some of the rivers on the east coast, but the quantity available is doubtful. The territory has not been fully examined.

The Government have now started a labour-recruiting agency in China. No Chinese coolie can be imported into the country except through that agency, or under permit from the Government. This will reduce the cost of introducing labour, agents' fees, etc., and also guarantee that the right sort of coolie is brought in.

Climate and Population.

The climate of North Borneo is tropical, hot, damp, and, therefore, somewhat enervating. The rainfall is about 120 inches at Sandakan, whereas Beaufort on the railway has 144 inches. The lowest reported in 1910 was on the Sapong Estate, 63·07 inches, falling on 229 days. The shade temperature ordinarily ranges from 72° to 94° F. the average being about 86°. In the interior the days are considerably hotter, and one feels the power of the sun more, but the nights are cooler.

The population, as shown by the census of 1911, is 208,183, including 355 Europeans. In 1901 the total number of persons enumerated was 104,527, but the census in 1911 was taken in a more efficient manner. It is no easy task getting the information from some of the people who neither read nor write. The Chinese have increased by 13,720, and a very important part they play in the interests of the country—in fact, they form perhaps the most valuable element in the development of the territory. Sometimes they are apt, especially the coolie class, to take collective action in the form of secret societies, which have to be promptly nipped in the bud. The Chinaman is industrious, frugal and intelligent; the richer are excellent men of business and are particularly just in their dealings. The majority of all classes can read and write their own script, and the second generation acquires an education of a European type with great facility.

The missions, especially the Roman Catholic, turn out some really smart youths as clerks. The bulk of the shop-keepers are Chinese. One finds a small shop even in remote districts. The Bajaus used to subsist by fishing and collecting sea produce, and they chiefly lived in boats, but now they are finding that to work for Europeans is more profitable, and some of them will take on a contract for clearing and felling jungle, and supplying round timber to the estates. In fact, under our rule, the Bajau is proving himself a good workman, and is building up a permanent home, in place of leading the roving, piratical life he was formerly accustomed to. In appearance the Bajau is small, active, dark,

Hosted by Google

with very bright, gipsy-like eyes, and straight black hair. As a body they are better looking than the Dusuns, or agricultural class, who accuse them, and very justly, of stealing their buffaloes and cattle. The Bajaus at the northern part of our territory have many ponies, which they ride fearlessly, spearing the great sambur deer while at full gallop. The Dusuns are the farmers of North Borneo. They number 87,951. They cultivate their land with *padi* and use ploughs. They also own cattle and buffaloes. In some of their villages they have married into Chinese blood, and the result is good. It seems to make them more industrious and frugal. It is quite a pleasure to walk through some of our model native agricultural villages, and see them all tending their crops, and the whole place properly irrigated. In this wet farming they use the same land year after year, and many of these native holdings have been demarcated, and the holders pay rent to Government. Now with the advent of the European planters their eyes are being opened to the fact that without a title-deed of some description from the Government they are apt to lose their land. One of the most important items in the work of the Land Office in 1910 was the settlement of native rights to isolated fruit trees, etc., when they were cut down by the rubber estates.

The Muruts number 25,314, and they are the people who, far away from civilisation, still indulge in head-hunting; as they advance in civilisation they will probably become Mohammedans. Their villages are very small, and often hidden far away in the jungle. A village sometimes consists of a single log hut divided up into cubicles, one for the use of each family, opening out on to a common verandah, along which the skulls captured by the tribe are festooned. The Muruts are probably the representatives of the aboriginals of the island. Both Dusuns and Muruts are too fond of the intoxicating liquor, which they manufacture from their corn.

The number of contract labourers imported during 1910 was 8,648, of whom 6,200 were Chinese, most of the remainder being Javanese. Medical examination of all these immigrants is compulsory, those being physically or mentally afflicted not being allowed to land. Most if not all of these labourers arrive with an advance outstanding against them, and for that they undertake to work a certain period, the advance being collected in monthly instalments—viz., by deductions from their pay. It is a bad system, but it cannot be avoided. A Malay or Chinaman does not appear to be, and, I believe, is not happy, unless he is indebted to his employer. A Malay is content to do a day's work for a day's pay, but a Chinaman prefers a fixed task where he can work more and earn more. The natives of the Sulu Archipelago, I see, have decreased by 870. These natives are related and intermarried with those of the Southern Philippines. They are fanatical and want very careful management. They have been a thorn in the side of the Americans in the Southern Philippines.

Administration.

For administrative purposes the territory is divided into nine provinces. The boundaries of these provinces are in some cases purely arbitrary, and not accurately defined. The form of government is modelled roughly upon the system adopted in the Malay States of the Peninsula. The Government is vested primarily in the Court of Directors which is appointed under the Company's charter, and may be compared to the Colonial Office in its relation to a British colony, though the Court of Directors interests itself more closely than does the Colonial Department in the smaller details of local administration. The supreme authority on the spot is represented by the Governor, under whom are the Residents of Sandakan East Coast, West Coast, Kudat, and the interior. Other districts are administered by district officers, who are also district magistrates, There are five treasuries, controlled by district treasurers, which is my department. Some of the heads of the departments are at Sandakan and some at Jesselton. I think it would be advisable in many ways to concentrate them all at Jesselton, which is nearer the cable and to Singapore, with which port most of our trade is done; at any rate, it requires consideration, as there are many interests of long standing bound up on the east coast. The Secretariat is under the charge of a Government Secretary, who ranks next in precedence to the Governor. The Government Secretary resembles the Colonial Secretary in a British colony, and his position is a most onerous one. In North Borneo we are fortunate in having men of the type of Mr. Pearson, who has just handed over the reins of Acting Governorship to our new Governor, Mr. F. R. Ellis, C.M.G., late of the Ceylon Civil Service.

Legislation is by proclamation of the Governor, but there is a council composed of the principal heads of departments and one unofficial member, which meets at irregular intervals. The Governor

Hosted by Google

is the chief judge of the High Court to hear appeals. Then there is the Sessions Court, administered by the Judicial Commissioner, and the Residents of districts are also Sessions Judges. The magistrates are divided into three Courts—first, second, and third—and their powers are defined by the Indian Procedure Codes and by local laws. The Headman's Court looks after native cases, with a limit as to jurisdiction. The Mixed Court, consisting of two native chiefs and one European magistrate, is a very useful tribunal for dealing with cases which the magistrate could no doubt settle himself, but which for political reasons he thinks should also be adjudicated upon by headmen.

The native chiefs are responsible for the preservation of law and order in their districts.

The Constabulary number seven officers and about 700 of other ranks; the nationalities include, besides British officers, the following: Sikhs, Pathans, and Punjabi Mohammedans, Chinese detectives, Malays, Dyaks, Filipinos and natives of the country. A criminal registry has been started, the finger-print system being adopted in the case of all vagrants and persons charged with offences punishable with imprisonment up to one year, or fine extending to $1,000.

Government gives a capitation grant to the three missions—S.P.G., Roman Catholic, and Basel. The S.P.G. have three stations, the Roman Catholics four, and the Basel four. There are eleven Chinese schools, with an aggregate of about 250 pupils. These schools are annually inspected by a Government officer. The Chinese have their joss-houses and the Mohammedans have their own mosques.

Finance, etc.

The principal sources of revenue are the excise farms previously referred to—they are in the hands of Chinese syndicates at present —the Customs inwards and outwards, poll-tax sanctioned by ancient native custom, and stamp duty. Revenue is derived from the rent on Government lands sold, transfer fees, etc. Judicial fees bring in a small amount, and the issue and sale of postage and revenue stamps has proved a fruitful source of income. The people of the country are by no means heavily taxed. A large number of the natives of the interior escape all payment of dues to the Company, the revenue being for the most part contributed by the more civilised members of the community residing in the neighbourhood of the Company's stations. I should like to add that there will be no export duty on rubber for fifty years from April 1st, 1905. There are bank agencies at Sandakan and Jesselton, and the Company does banking business if required. The State, which has adopted the penny postage, is in the Postal Union, and money orders and postal orders payable there are issued in the United Kingdom and in most British colonies, and *vice versa*. There is a Government note issue for use within the territory only. The currency is the Straits dollar, valued at 2*s.* 4*d.* by the Straits Government, although the bank rate is very slightly higher or lower according to whether the banks are buying or selling drafts on London. The Company has its own copper and nickel coinage. In the interior the principal medium of exchange among the natives is the large earthenware jars, imported originally, it is believed, from China, which form the chief wealth both of tribes and individuals.

The bulk of the trade is with, or through, Singapore, and is carried almost entirely by the North German Lloyd steamers. A Chinese firm of Singapore started a cargo steamer or two, but abandoned the enterprise. The timber trade is mostly with Hong-kong, and is carried by one North German Lloyd and one British steamer. These convey, in addition, copra, cocoanuts and sundries, bringing back kerosene oil and manufactured goods. Interport trade is carried on by the Sabah S.S. Co.

Sir West Ridgeway, Chairman of the Company, has quite recently paid a visit to the country, and has, no doubt, conferred with the Governor on many points, and prepared a programme for further developments. Progress has been constant, and the country is quite different from what it was when I first went out in 1898. The communication and mails were then so irregular that no one knew when they might arrive or when they might depart. Jesselton as a port of call for Singapore steamers was then unknown. A captain said, "I believe there is some little place behind the island, but we do not go in there." He meant the island of Gaya, which forms the protection for Jesselton, and the little place he referred to was, if I remember correctly, Gantian. We now have three steamers running regularly between Singapore and our ports, all time-tabled to fit in with the German mail vessels homeward and outward bound, and I believe the N.D.L. think of putting on a fourth vessel.

[A large number of kinematograph views of British North Borneo, recently taken by Mr. Cherry Kearton, were exhibited and described by him.]

DISCUSSION.

The Chairman, in proposing a hearty vote of thanks to the author for his admirable paper, and to Mr. Kearton for the views he had shown, said that the taking of the kinematograph views was a marvellous achievement in view of the difficulties which Mr. Kearton must have encountered in obtaining the pictures, which enabled the audience to realise, as they could never have realised otherwise, that far-away dependency of the Empire. Personally, he felt the greatest interest in North Borneo, having had the advantage of visiting the coast and knowing something of the inhabitants. He had had the privilege of sitting for a time on the Board of the British North Borneo Company, and he was able to contrast the existing condition with that which obtained many years ago. The progress had been wonderful. He remembered the beginning in the first days under the advice of, among other people, that gallant sailor Sir Harry Keppel, and the idea then was that North Borneo was to be a power by sea, and that they were to have a vessel of war powerfully armed and well manned. That vessel more than exhausted all their resources. They were obliged to abandon the ambition of maintaining a navy, and to rely upon the Imperial forces for their protection, and they had to do what they could with their resources in the development of the country. Matters did not advance very quickly. There were brave and capable people out in Borneo when he was there, but nothing had presented itself at that time which gave much promise. There was a timber company, and he remembered that, before leaving, he thought that he ought to make some return for all the kindness that had been shown to him by trying to do something for the development of the country. Under the advice of a then resident he put a certain sum into a timber company. The company had a bad time for many years. They were too ambitious. But he was glad to say that things were mending at last, and that, as they had heard from Mr. Lovegrove, important changes had taken place, and there was traffic between the Borneo forests and the market of Hong-Kong. Besides this, a good deal of that fine timber pavement which was laid down in London came from the part of the country which produced hard wood. A change had come over the spirit of the dream. He believed that the first windfall for North Borneo was the discovery and the use of a tobacco of very superior quality. The cultivation was, however, attended with some difficulty, as so often happened in tropical countries. When the soil was first broken up a miasma arose which was fatal to life. There was much suffering, and various unhealthy conditions prevailed in the beginning of the cultivation, but finally the tobacco industry was successfully established in North Borneo. Then they had come in later days to the rubber industry. That was a very striking and interesting subject. There were comparatively few persons who had sufficient fortitude to resist altogether the temptation to make a little plunge into rubber, and there had been varying results. He only hoped that those who had made the plunge in Borneo would be well rewarded for their enterprise. Then it had been found that the Chinese were, as was now known, a most suitable people for opening up a country. It was very interesting to hear how much the natives could do for themselves. That was a marvellous climbing feat shown in one of the pictures in which the man went up the tree for cocoanuts. The copper mining shown in the pictures was remarkably like the best practice among English people. Borneo was a specimen of what was achieved all over the world. The position which had been reached by their own little island with its small resources was marvellous, but it would not have been attained unless Englishmen had been enterprising in opening up countries far and wide over the surface of the earth. North Borneo could not be compared with the greatest dependencies which Great Britain had in the tropics, but it was typical of what our brethren were doing beyond the seas. Large and deep should be the gratitude which those who lived at home at ease ought to feel to the men and women who went forth as pioneers and endured all the hardships and strain of a tropical climate, carrying more or less their lives in their hands, and who by their labour built up the greatness of the Empire.

Mr. Edward Dent thought that one feature which was very satisfactory about Borneo at the present time was the increase among the natives. Papers which had been read before the Society in former days—one by Mr. Francis Cobb in 1834, and one by Mr. Henry Walker in 1903—showed that the population of Borneo was far greater formerly than it was at the present time. The population had decreased very much in consequence of small-pox, head-hunting, and other causes. Mr. Pryer, who was one of the first Englishmen to go out to Borneo, said that only in 1878 there were no less than 160 natives killed on the coast by pirates. Now piracy had quite died out, and, according to the last census, the native population had nearly doubled. Another way in which the population had been increased was by the addition of Chinese. Mr. Walker stated in 1903 that there were 13,000 Chinese in Borneo, whereas last year there were 26,000.

Mr. Cherry Kearton said that within the last three years he had gone round the world with the exception of crossing the Pacific Ocean. He had seen many countries and been in many corners of the earth and many outlandish places. He had been in East Africa, as far as Uganda, and right on the German border. On his second visit to East Africa he had fever very badly and nearly died, and when he came back he heard something about Borneo and decided to make a trip to that country. Before he started, a gentleman in the City told him that Borneo was a fever-stricken place as "all those South American States are." When he went to Borneo, being a naturalist, he was very keen on

photographing the ourang-outang. Growing tired of canoeing in a "dug-out," from which he was frequently pitched out, he took a short cut through the jungle and was sometimes cutting his way through for four or five days at a time. He was out at nights and got very nearly drowned, and although he went through the whole of the central part of the country he never had a touch of fever. When he left Borneo he went to Mysore, and stopped out for seven or eight nights, and then came to England. He thought that, notwithstanding all this, he looked a very good specimen of health. When he was in Borneo he used to go in for gymnastics a great deal. He ran races with British seamen and American seamen on Coronation Day, and he won three races out of four. If a man took care of himself he could get on all right in Borneo. There was a fine opening in that country for any young fellow who liked to go out and work. Work was the keynote. He thought that, if Borneo had as good an advertising agent and Governor as East Africa had, it would be level with British East Africa, for they had got the game there. Scores of people went to East Africa for the game. If Borneo had an experimental farm, which they could easily have up on the mountains, and if the rivers and pools were stocked with the new discovered fish which feeds on the mosquito lava, the river banks would soon repopulate, and they would be able to support plenty of labour. There was also English shipping wanted. He found that he had to go by a German boat from Singapore to Borneo. The same thing happened in British East Africa only two years ago. He could show a photograph of three foreign ships in the harbour of Mombasa and no British ship. When people invested their money and went out to prospect a country like Borneo, the English people ought to help them in every possible way. The men had to work all the time under difficulties, and he had a great admiration for them. They were doing a great and noble work.

Dr. S. G. Kirkby-Gomes said he had been in British Borneo for three and a half years, and while he was there he was associated with the author, who, as district treasurer in North Borneo, found it his duty to collect as much money as he possibly could for the Government, whereas it was the speaker's duty as a district surgeon and a custodian of the health of the people to spend the money, and for these reasons Mr. Lovegrove and himself often had little differences of opinion. When he heard at the beginning of the present session of the Society that a paper on British Borneo was to be read and that the author was to be Mr. Barraut, a former Resident in that country, he told the secretary of the Colonial Section that he thought the Society had been very fortunate in obtaining the promise of a paper. That gentleman was, he believed, about the best authority on British Borneo either in it or out of it. Unfortunately, however, Mr. Barraut was obliged, owing to ill-health, to defer his paper, but it was very gratifying to find that his place had been taken by so able an official as Mr. Lovegrove. The paper gave a very comprehensive view of British Borneo, and he had no doubt that most of those present had obtained a very good and intelligent idea of what the country was. Mr. Kearton had told the meeting that some one spoke to him of British Borneo as being in South America. He (Dr. Kirkby-Gomes) had often heard it spoken of as being a little place in China. It was, as the audience all knew, the second largest island in the world. Mr. Lovegrove in his paper had avoided some dangerous ground. For instance, he did not tell them anything with regard to the health of British North Borneo. He did not tell them that there was a considerable amount of malaria, dysentery, and other diseases there; but Mr. Dent had given them a hint on the subject, and it was well known that Sir West Ridgeway was now in British Borneo making careful inquiries with regard to this matter. He had as his adviser Sir Allan Perry of Ceylon, the able and experienced principal medical officer of that island. The medical department of British North Borneo with which he (the speaker) was connected for several years was now undermanned and underpaid as well. He hoped that Sir Allan Perry's report would be the means of meeting those defects. They would all agree that, whatever revenue was wanted for anything else, the health of the country ought to be maintained.

Mr. Byron Brenan, C.M.G., in moving a hearty vote of thanks to Mr. Lovegrove for his admirable paper, said that the author in a very short paper had taught the audience more about North Borneo than any of them could have learned from all the geographies and histories in their libraries. Both he and Mr. Kearton had made the place exceedingly attractive to them. They had had to suffer the heat and burden of the day, and the audience had been able to listen to an account of their experiences. He hoped that the advice of one of the speakers would be followed, and that many young men would go out and help to develop the country. He spoke feelingly, for he was one of the many persons who had had a little venture in rubber shares, but so far the result had been disastrous. There was much to be learnt from the paper and also from the pictures. He wished that some agricultural labourers had been present to see the pictures, and to observe the zest and energy which the agriculturists of Borneo put into their work. On behalf of the Colonial Section of the Society he wished to express to Earl Brassey most cordial thanks for his great kindness in presiding.

The vote of thanks was seconded by Mr. C. V. Creagh, C.M.G., a former Governor of British North Borneo, and carried.

Earl Brassey acknowledged the compliment, and expressed his personal gratitude to Mr. Lovegrove and Mr. Kearton.

LIGNO-CONCRETE.*

In the introductory remarks the author refers to the use in America and Australia of concrete in combination with timber, and points out that while the concrete effectively preserves the timber, it is not used to the greatest advantage. The object of the author's investigations was to ascertain if it were possible to reinforce concrete with timber rods. Roughly speaking, steel is about eight or nine times stronger than timber, but ten to fifteen times as expensive. The efficiency of timber, as a reinforcing material, depends on whether there is sufficient adhesion between the timber and the concrete, and whether the difficulties of the absorption of moisture by the timber from the wet concrete, and the splitting the latter, can be overcome.

The paper describes the experiments made by the author to ascertain (*a*) the amount of water absorbed by eighteen kinds of timber immersed in fresh water, along the grain and through the end grain respectively; (*b*) the relative absorption by the timber of fresh and sea water in the same period; (*c*) the relative amount of water absorbed by timber embedded in 6 to 1 concrete and neat cement blocks; (*d*) the effect of applying wood preservative, creosote, varnish, etc., to the timber before insertion in the concrete or cement blocks; (*e*) the effect on the adhesion between the timber and the concrete of soaking the rods before insertion. Examples are given to show that concrete effectively preserves timber embedded in it.

Particulars are given of the construction of twenty-five concrete beams reinforced by timber rods. Three ligno-concrete beams, 8 inches deep by 4 inches wide, were tested with a central load on a 4-foot span; the average ultimate load producing fracture was about three tons. The results of these tests are compared with the tests on ferro-concrete beams recorded by Mr. E. Marburg in the "Proceedings of the American Society for Testing Materials" (1904, Vol. IV.). It appears that for the same ultimate strength of beam, it is necessary to use 9 per cent. of sectional area of pitch-pine tensile reinforcements as against 1 per cent. steel reinforcements. A comparison of the prices of steel and pitch-pine shows a saving in favour of ligno-concrete.

As the author points out, in cases where more than about 1·2 per cent. of steel reinforcement is required, ligno-concrete cannot compete with ferro-concrete, because the required size of the timber bars would be too large for convenient use. There appears, however, to be a big field for it for use in constructing bungalows, buildings for small holdings, floors, piles, posts, fencing, coast and river works, etc. It has already been used for making fence-posts and for building a short length of sea-wall. The ligno-concrete fence-posts cost about two shillings per cube foot. They are about 20 per cent. cheaper than creosoted deal, and about 40 per cent. cheaper than English oak. In Canada four bungalows have been built with ligno-concrete slabs, and the Pacific Coast Construction Company of Victoria, British Columbia, now have contracts in hand for twenty buildings in which this material is to be used.

* Abstract of a paper read by Mr. Gerald O. Case before the Society of Engineers.

THE RUBBER-PLANTING INDUSTRY.

The Imperial Institute has compiled a selection of reports relating chiefly to the composition and quality of the rubber furnished by well-known rubber-producing trees grown in different countries, and under different climatic conditions, and prepared in different ways. On the whole, the cultivation of *Hevea Braziliensis* in the districts suitable for its growth is more profitable than that of any other known rubber tree, and the product holds a great advantage as against the rubber collected from wild vines and other rubber-producing trees, owing to its purity and greater elasticity and strength. In an introduction to the report, Mr. W. R. Dunstan, Director of the Institute, says:—

"The rubber-planting industry is now in a transition stage, and is faced with several problems which will only be satisfactorily solved by systematic research, much of which must necessarily be conducted on the spot. It is a welcome and hopeful feature that this need for investigation is generally recognised, and not only are these problems being attacked by the Government Agricultural Departments in the Tropics, many of which are conducting investigations in conjunction with the Imperial Institute, but many of the larger plantation companies have engaged the services of scientific specialists to conduct investigations into the important problems of tapping, coagulation, curing, and the large subject of the hygiene and pathology of rubber plantations, upon the successful solution of which the future of this great industry depends.

"So long as rubber commanded a very high price, considerable importance attached to those plants which furnished even a relatively small amount of this material, since the profitable separation of the rubber from resins and other foreign substances naturally associated with it in the latex was commercially possible. With a very considerable fall in the price of rubber, and with a greatly enhanced production of first-class rubber, these secondary and inferior sources of the material are less likely to be of importance. A number of such products are alluded to in the reports, some of which also relate to gutta-percha, which is closely allied in some respects to rubber, and was once very extensively employed and purchased at a high price for certain electrical purposes. Now, however, the commercial position of gutta-percha is greatly changed, owing to the fact that rubber itself, in combination with other substances, can be employed for many of those purposes for which gutta-percha was not long ago alone suitable.

"Lastly, reference is made to the investigations conducted at the Imperial Institute into the value

Hosted by Google

of the seeds of the Para rubber tree as a source of oil. It is now some years ago since the oil contained in these seeds was first investigated as to its composition and uses at the Imperial Institute. It was shown that the kernel of this seed, which is easily removed from the thin shell, contains nearly half its weight of oil. This oil was found closely to resemble linseed oil in its composition and properties, falling into the class of drying oils, which are used in the manufacture of paints, of linoleum, and of other materials. It was shown that this oil would command about the same value as linseed oil, and that there would be a considerable demand for it as a substitute for linseed oil. With the maturing of large rubber plantations all over the world, the need for seed for planting is rapidly diminishing, and an enormous quantity of seed is becoming available. The present time is favourable for the production of rubber-seed oil, since it now will command a higher price than that originally quoted, owing to the scarcity and consequent greater value of linseed oil."

THE PUBLIC TRUSTEE'S REPORT.

The fourth annual report of the Public Trustee shows that remarkable progress has been made since 1910, when Mr. C. J. Stewart read a paper before the Society on the work of his department. The first Public Trustee was appointed for a period of five years: of these, four and a half have now elapsed. The business transacted during this period is shown by the following figures:—

		Value.
1908 (3 months)	63 cases accepted	£384,317
1908–9 . . .	381 " "	3,133,523
1909–10 . . .	622 " "	4,989,191
1910–11 . . .	877 " "	6,548,641
1911–12 . . .	1,050 " "	8,626,315
	2,993	£23,681,987
Trusts in course of being transferred, 126		£1,000,000
Current business up to March 31st, 1912		£24,681,987
Applications from intending testators requesting that the Public Trustee should act as executor, 2,020 . .		£44,030,000
Total value of the business of all kinds negotiated since January 1st, 1908.		£68,711,987

As this business is growing from day to day, it may be said to be approximating in value to the sum of £70,000,000; 198 estates have been distributed at a value of £2,357,774; 1,166 wills have been deposited for safe custody. The growth of the fees shows an increase as satisfactory as the value of the business itself. The fees were:—1908 (three months), £502; 1908–9, £6,075; 1909–10, £16,640; 1910–11, £24,321; 1911–12, £34,208.

For the past financial year, after taking the £34,000 in fees and spending £29,000 in expenses, there is a surplus left of £5,000. The fees have increased as compared with the previous year by 40 per cent., the expenses incurred in earning these increased fees have increased by 34 per cent., while the surplus of assets over expenditure has increased by 86 per cent.

For the first eighteen months the Department was working at a loss, but the deficit has been obliterated; and for the last three years the Department has shown an increasing surplus—viz., 1909–10, a surplus of £1,521; 1910–11, a surplus of £2,730; 1911–12, a surplus of £5,080. The present financial position is that there is a surplus in cash and also of fees earned (but at the moment uncollected), furniture, and stores, of some £11,000 in value.

NOTES ON BOOKS.

Lectures on Cement. By Bertram Blount, F.I.C. London: The Institute of Chemistry of Great Britain and Ireland. Price to persons not connected with the Institute, 2*s.* 6*d.*

A few months ago the Council of the Institute of Chemistry decided to institute a scheme under which Fellows who have special knowledge and experience in various branches of work, should deliver courses of lectures chiefly for the benefit of young chemists and advanced students, such as those preparing for the final examination for the Associateship of the Institute. The object is to indicate the scope and character of the work actually carried out in various branches of professional practice as distinct from purely academic training. The scheme was inaugurated by this course of lectures, which was delivered before the Institute at King's College, London, on October 26th and December 1st, 1911.

The lectures contain an historical account of the evolution of calcareous cements, including a long and interesting extract from Smeaton's description of the steps he took to obtain a suitable cement for Eddystone Lighthouse. After dealing with chemical reactions and physical changes in the setting and decay of cements, modes of testing, standardisation, the uses of cements, and the causes of failure of cement structures, Mr. Blount devotes some space to what is perhaps the most characteristic feature of this course, viz., the necessary equipment of knowledge and training for an expert, the difference between the conditions of work in a laboratory and in a workshop, and the necessity of learning to think in tons instead of grammes, in steel and fire-brick instead of platinum and porcelain.

There can be no doubt of the practical advantages of such a course to the young cement chemist, nor could the Council of the Institute have found a more suitable lecturer for the purpose than Mr. Blount.

Furniture. By Esther Singleton. New York: Duffield & Co. $7.50 net.

Miss Esther Singleton's book might almost be called an encyclopædia of furniture, for it is

Hosted by Google

pre-eminently a volume to be consulted rather than to be read straight through. The authoress is well known in her own country as a writer and also as a collaborator on more than one encyclopædia, and her training and skill in this kind of work have stood her in good stead in the present volume, for she has gone to the best sources, and has used them freely and judiciously. She has, moreover, provided her work with an excellent index, which greatly facilitates its use.

There must be many people who would find this book far better suited to their needs than larger and more cumbrous volumes dealing with furniture and its history, and it is a much more serious work than the majority of comparatively small handbooks on the subject. On the other hand, the work is doubtless better adapted to meet the demands of the American public—to whom, of course, it is primarily addressed—than to appeal to the ordinary British reader. In the first place, a great many of the illustrations are taken from specimens in the Metropolitan Museum at New York, which is obviously the right thing in an American book; but the first thought of the reader on this side of the Atlantic is that he could find more interesting examples nearer home.

Further, the author is concerned mainly with the history of furniture, and this is treated, as many Americans like art-history to be treated, with a name for every minute variation of style, and a good deal of shyness over recognising periods of transition. That is a point of view which is less common in this country, or at least less openly avowed; but once it is granted, Miss Singleton's book must command our respect. It is a conscientious and thorough piece of work, and a large amount of information is compressed into its pages.

GENERAL NOTES.

Musical Instruments at the Victoria and Albert Museum.—Their Majesties the King and Queen have been graciously pleased to deposit on loan at the Victoria and Albert Museum an interesting group of musical instruments. The loan consists of a harmonium, a piano, and a harpsichord. The harmonium, made by Ale. Muller, of Paris, was specially constructed for travelling and can be fitted into a small leather trunk, which is exhibited beside it. This instrument was formerly used on the royal yacht. The piano is an early specimen of the upright grand type, and was made in 1808 by "R. Jones, Upright, Grand and Square Piano-forte maker To His Royal Highness The Prince of Wales, No. 11 Golden Square, London, W." It was therefore presumably constructed specially for George IV. when Prince of Wales. The most important and interesting piece of the three is the harpsichord, which is said to be the original one bequeathed by Handel to King George II. It was made by Hans Ruckers the elder, the first of that celebrated family of Flemish musical instrument makers who worked in Antwerp. It is inscribed "Joannes Rvckers me fecit Antverpiae, 1612," and bears the characteristic "rose" trade-mark representing a seated angel playing a harp between the letters "H.R."

A New Indian Journal.—Messrs. G. A. Vaidya-Raman & Co., of Madras, have just published the first number of the *Wealth of India*, a monthly journal of information and instruction dealing with all topics of material interest. It contains thirty-two pages of reading matter of crown quarto size, and is a digest of facts, figures, and information on all questions relating to industrial, commercial and economic progress. The section entitled "Views and Reviews" contains the cream of the articles on economic questions in periodicals not easily accessible to Indian readers, while the "Notes and Comments" include a variety of subjects including Agriculture, Commerce, Industry, Economics, Co-operation, Banking, Insurance, Scientific and Technical Education, Economic Products, Business Methods, Frauds and Fakes, Machinery and Invention, Industrial and Economic Literature, and Openings for Business.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

April 17. — John Henry Coste, F.I.C., "Municipal Chemistry." Dr. Rudolph Messel will preside.

April 24.—George Fletcher, Assistant Secretary of the Department of Agriculture and Technical Instruction, Ireland, "Technical Education in Ireland."

May 1. — William Burton, M.A., F.C.S., "Ancient Egyptian Ceramics."

May 8.—E. D. Morel, "British Rule in Nigeria."

May 15. — Ernest Kilburn Scott, Assoc. M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere." Sir William Ramsay, K.C.B., Nobel Laureate, F.R.S., will preside.

May 22. — Gordon Craig, "Art of the Theatre." Miss Ellen Terry will preside.

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

April 25.—Sir John O. Miller, K.C.S.I., "The Central Provinces." The Rt. Hon. Lord MacDonnell, G.C.S.I., K.C.V.O., will preside.

May 16.—Neville Priestley, Managing Director, South Indian Railway, "Indian Railways."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

May 7.—Alan Burgoyne, M.P., "Colonial Vine Culture."

May 21.—The Hon. J. G. Jenkins, "Australian Railways."

Hosted by Google

HOWARD LECTURES.

Monday evenings, at 8 o'clock :—

CAPTAIN H. RIALL SANKEY, R.E. (retd.), M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

April 29, May 6, 13, 20.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 15...Brewing, Institute of (London Section), Criterion Restaurant, Piccadilly, W., 8 p.m. Mr. E. Hatschek, "Colloidal Chemistry and Brewing."

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. R. M. Kearns, "The Cost of Labour in Connection with the Erection and Maintenance of Buildings."

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. (Graduates' Section.) Mr. F. Burge, "Steam Tractors."

Victoria Institute, 1, Robert-street, Adelphi, W.C. 4.30 p.m. Rev. Professor G. Henslow, "Directivity of Life, as seen in the Structure of Plants and Animals."

Architectural Association, 18, Tufton-street, S.W., 7.30 p.m. Mr. L. Weaver, "Some Scottish Houses of the Renaissance."

TUESDAY, APRIL 16...Illuminating Engineers, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. H. W. Y. Webber and Mr. W. R. Rawlings, "The Lighting of Private Houses by Gas and by Electricity."

Asiatic, 22, Albemarle-street, W., 4 p.m. Mr. E. T. Richmond, "The Significance of Cairo."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. E. Gosse, "Algernon Charles Swinburne: his Early Life and Work." (Lecture I.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. 1. Hon. Sir Francis J. E. Spring, "The Remodelling and Equipment of Madras Harbour." 2. Mr. H. H. G. Mitchell, "The Alteration in the Form of Madras Harbour."

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. Alfred Watkins, "New Methods of Speed and Gamma Testing."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8 30 p.m. Mr. E. T. Powell, "The Faith of an Imperialist."

WEDNESDAY, APRIL 17...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. J. H. Coste, "Municipal Chemistry."

Meteorological, 25, Great George-street, S.W., 7.30 p.m. 1. Messrs. J. E. Clark and R. H. Hooker, "Report on the Phenological Observations for 1911." 2. Messrs. R. G. K. Lempfert and W. Braby, "A Method of Summarising Anemograms."

Geological, Burlington House, W., 8 p.m. 1. Mr. H. H. Thomas and Professor O. T. Jones, "The Pre-Cambrian and Cambrian Rocks of Brawdy, Hayscastle, and Brimaston (Pembrokeshire)." 2. Professor O. T. Jones, "The Geological Structure of Central Wales and the Adjoining Region."

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Mr. J. D. Siddall, "Note on the Life-history of a Marine Diatom from Bournemouth." 2. Mr. E. B. Stringer, "On a Modified Form of the Lever Fine-adjustment and a Simple Turn-out Device for the Substage Condenser."

United Service Institution, Whitehall, S.W., 3 p.m. Brigadier-General H. De B. De Lisle, "The Strategical Action of Cavalry."

Royal Society of Literature, 20, Hanover-square, W., 5.15 p.m. Lecture by Professor W. L. Courtney.

Royal Archæological, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. 1. Dr. Talfourd Ely, "Excavations near West Marden and in Hayling Island." 2. Dr. Philip Nelson, "The Fifteenth-Century Painted Glass in the Church of St. Michael, Ashton-under-Lyne, depicting Events in the Life of St. Helena."

Engineers, Junior Institution of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Mr. E. Kilburn Scott, "The Lay-out and Erection of Electric Power Plant."

THURSDAY, APRIL 18...China Society, Caxton Hall, Westminster, S.W., 8.30 p.m. Mr. L. Giles, "The Great Chinese Encyclopædia."

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Linnean, Burlington House, W., 8 p.m. 1. Dr. D. H. Scott, "On *Botrychioxylon paradoxum*, a Palæozoic Fern with secondary wood." 2. Dr. E. A. Newell Arber, "On *Psygmophyllum majus*, sp. nova, from the Lower Carboniferous Rocks of Newfoundland, together with a Revision of the Genus, and Remarks on its Affinities." 3. Mrs. Henshaw, "The Alpine Flora of the Canadian Rocky Mountains."

Chemical, Burlington House, W., 8.30 p.m. 1. Mr. E. Hope, "The Condensation of Ethyl Sodiomalonate with Ethyl Citraconate and the Synthesis of β-Methyl Tricarballylic Acid." 2. Mr. J. J. Sudborough, "The Formation and Hydrolysis of Esters of Ketonic Acids." 3. Mr. L. A. Levy, "Studies on Platinocyanides." 4. Dr. A. G. Perkin, "Purpurogallin." (Part II.) 5. Messrs. H. Davies, H. Stephen, and C. Weizmann, "$\alpha\alpha^1$-Derivatives of Adipic and β-Methyl Adipic Acids. Preliminary Note." 6. Mr. S. Ruhemann, "Methylenedioxy-triketohydrindene." 7. Mr. P. May, "Aromatic Antimony Compounds. Part IV.—Compounds of Antimony Trichloride with Diazonium Chlorides." 8. Messrs. F. Tutin and H. W. B. Clewer, "Note on the Constituents of Rhubarb." 9. Mr. R. Wright, "Molecular Weight Determinations from the Relative Lowering of the Vapour Pressure of Ethereal Solutions." 10. Mr. H. D. Law, "Electrolytic Reduction. Part VI.—Unsaturated Aldehydes and Ketones." 11. Mr. J. E. Myers, "A Method of Estimating Potassium Iodate."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. W. Crossley, "Synthetic Ammonia and Nitric Acid from the Atmosphere." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. Haldane Macfall, "Has Modern Painting any Lessons for the Artist-Photographer?"

Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Discussion on "The Causes Preventing the more General Use of Electricity for Domestic Purposes."

Historical, 7, South-square, Gray's Inn, W.C., 5 p.m. Mr. Louis Felberman, "St. Margaret of Scotland."

Mining and Metallurgy, at the Geological Society, Burlington House, W., 8 p.m.

FRIDAY, APRIL 19...Royal Institution, Albemarle-street, W., 9 p.m. Mr. A. O. Campbell Swinton, "Electricity Supply, Past, Present and Future."

Medical Officers of Health, 1, Upper Montague-street, W.C., 5 p.m. Dr. J. A. Gibson, "The Housing (Inspection of Districts) Regulations, 1910."

Brewing, Institute of (Yorkshire and North-Eastern Section), Queen's Hotel, Leeds, 8 p.m. Mr. Percy Russell, "Fine Grinding of Malt."

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Dr. Walter Rosenhain and Mr. S. L. Archbutt, "Tenth Report to the Alloys Research Committee: On the Alloys of Aluminium and Zinc. With a Short Appendix on a Ternary Alloy of Aluminium with Zinc and Copper."

SATURDAY, APRIL 20...Royal Institution, Albemarle-street, W., 3 p.m. Mr. R. Blomfield, "The Architecture of the Renaissance in France. Lecture I.—1494–1547. The Amateur."

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,100. VOL. LX.

FRIDAY, APRIL 19, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

WEDNESDAY, APRIL 24th, 8 p.m. (Ordinary Meeting.) GEORGE FLETCHER, Assistant Secretary of the Department of Agriculture and Technical Education, Ireland, "Technical Education in Ireland." R. BLAIR, M.A., B.Sc., Education Officer of the London County Council, will preside.

THURSDAY, APRIL 25th, 4.30 p.m. (Indian Section.) SIR JOHN O. MILLER, K.C.S.I., "The Central Provinces." THE RIGHT HON. LORD MACDONNELL, G.C.S.I., K.C.V.O., will preside.

Further details of the Society's meetings will be found at the end of this number.

CONVERSAZIONE.

The Council have decided that the Society's Conversazione shall in future be held biennially instead of annually, and that no Conversazione shall be held this year.

PROCEEDINGS OF THE SOCIETY.

SEVENTEENTH ORDINARY MEETING.

Wednesday, April 17th, 1912; RUDOLPH MESSEL, Ph.D., F.C.S., President of the Society of Chemical Industry, in the chair.

The following candidates were proposed for election as members of the Society:—

Archer, Captain F., Main-road, Akyab, Burma.

Astley, Rev. Hugh John Dukinfield, M.A., Litt.D., The Vicarage, East Rudham, Norfolk.

Barnes, Charles A. Albert, Assoc.M.Inst.C.E., Government Survey Schools, Lagos, West Africa.

Eades, C. T., Beech-grove, Cheshom Bois, Bucks.

Jasonidy, Omphrius John's, Blondel-street and Empress Ireni-street, Limassol, Cyprus.

Jones, Bassett, Jun., 1, Madison-avenue, New York City, U.S.A.

Laut, Miss Agnes C., Wassaic, Duchess County, New York, U.S.A.

Line, Charles Arthur, 39, Beaufort-road, Edgbaston, Birmingham.

Mackinney, Valentine Henry, Deancot, 85, Woodstock-avenue, Golder's Green, N.W.

O'Connor, H. J. Courtenay, Limehayes, Killyon-road, Larkhall-rise, S.W., and Bathurst, Gambia, West Africa.

Robins, Herbert George, c/o Tanganyika Concessions, Ltd., Lulua Poste, via Elizabethville, Katanga, Belgian Congo.

Skrimshire, Alfred J., 31, Ryde Vale-road, Balham, S.W.

Weir, Charles James, Moorcroft, Silvermere, Cobham.

The following candidates were balloted for and duly elected members of the Society:—

Beecroft, D, The Class Journal Co., 231-241, West 39th-street, New York City, U.S.A.

During, Claudius Dyonisius Hotobah, 15, Pulteney-street, Freetown, Sierra Leone, West Africa.

Hartley, Frank Reginald, 3, Esplanade-road, Scarborough, Yorks.

Jenner, Harry, 35, Auckland-road, Ilford, Essex.

Markel, Karl Emil, Ph.D., 20, Queen's Gate-terrace, S.W.

Stockdale, William, Rosebank House, Stubbins, near Manchester.

Sutherland, William George, The Birches, Ashton-on-Mersey.

The paper read was—

MUNICIPAL CHEMISTRY.

By J. H. COSTE, F.I.C.

Although the passing of the Local Government Act, 1888, marked a definite epoch in the evolution of local government and led to a broader conception of the duties of municipal corporations, it must not be forgotten that great progress had been made in the internal public service of this country before that time.

Hosted by Google

This Act was rather the result of the feeling that

"Of good things none are good enough,"

and possibly that

"Of old things all are over old,"

than that nothing then existing was good in local administration. That it gave a great stimulus to municipal life is undoubted, and it is certain that the people of to-day would not be satisfied with the public services which sufficed their grandfathers.

The complexity of the duties of municipalities, even of the smaller ones, has led to the need of a class of officers who formerly were only required by the greater bodies and whose duties are advisory rather than administrative. When the duties partake of the latter character they are of a kind which were not utilised or, indeed, available until the nineteenth century had run great part of its course. Such officers are the medical officers of health, a relatively new type of medical man, engineers, architects, and, more particularly, analytical and consulting chemists.

I propose to indicate briefly the various classes of services which are rendered by chemists to local authorities, and, further, to consider the special qualifications and experience which are required of such chemists.

I.

(i.) The first class comprises those duties which are imposed by Act of Parliament, and which necessitate or imply the creation of certain statutory appointments. The officers appointed have specific duties often in themselves of a routine character, but which only attain to their full utility when carried out by a chemist of some experience.

(1) The oldest group of Acts under which *ad hoc* appointments of this kind are made are those regulating the great gas industry. The Metropolitan Gas Act, 1860, Section 27, provided, as a condition of districting of the thirteen companies then in the Metropolis (which now, by successive amalgamations are reduced to three), and the consequent creation of monopolies, that the gas supplied by them should be tested to ascertain that a prescribed standard of quality was maintained, and that "Every local authority taking any supply of gas according to this Act . . . shall appoint . . . a Chemical Examiner or Gas Engineer or other Competent Person to be an Examiner for the Purposes of this Act." The various Acts relating to the Metropolis and to the provinces, more particularly in the latter case the Gas-works Clauses Act, 1871, have provided that testings shall or may be made. It will be noted that, although great latitude is allowed in the qualifications of the persons to be appointed, a chemical examiner is mentioned first, and the only actual requirement is competency—and, in later Acts, the very obvious one of impartiality. The greater part of the work, the determination of illuminating power, and, in some places, the much more important calorific power, is physical rather than chemical; but it has long been associated with the chemist, partly perhaps because it is recognised that gas-making is essentially a chemical industry and that the physical properties of gas are determined principally by its chemical composition. Although the work is in itself of a routine character, and the methods are rigidly prescribed, it is obvious that a knowledge of the principles underlying them is to be desired in all cases, and, when an examiner is also adviser on gas matters to his authority, an intelligent and in some respects a sympathetic knowledge of the modern conditions of gas-making is necessary, in order that the advice tendered may both safeguard the public interest and allow the legitimate and economical expansion of a great industry on which has been conferred the important duty of utilising to the best advantage a large proportion of our limited supply of fuel.

(2) Another group of Acts, the earliest of which (1871) is now of respectable antiquity, relates to the sale and storage of petroleum, matters seriously affecting the public safety. The officer mentioned in the Acts appears to be rather a sampler than a chemist or tester, but nevertheless it has been held to be safer to appoint a testing officer. Although in many places the chief constable or inspector of nuisances does this work, the modern uses of petroleum products and of materials equally inflammable with petroleum, but not coming within the purview of the Acts, render the possession of considerable chemical knowledge a *sine qua non* for the proper conduct of such examinations. More especially is this the case since a legal decision and a subsequent Order in Council have confirmed the view held by one testing authority that the Acts applied to *mixtures* containing petroleum. A consideration of the dangerous properties of some petroleum products, and of the more or less allied bodies which the law includes under the general name of petroleum, will point to the desirability that these Acts should be vigorously but, in view of the great and rapidly-growing uses of petroleum, judiciously administered.

Hosted by Google

(3) The quality of the food of a nation, more particularly that of its children, is a matter of the utmost importance, and, unfortunately, the temptation to tamper with it is apparently very great. If gross adulteration is now but little practised there are, nevertheless, many cases in which the public, if not actually poisoned or starved, is cheated by being given articles which are "not of the nature, substance and quality demanded." The Food and Drugs Act, 1872 (Section 5), gave power to the local authorities of a district to "appoint...one or more persons possessing competent chemical and microscopical knowledge as analysts of all articles of food, drink and drugs purchased within the district." Since this Act several others have been passed with a view to securing a better control over the quality of foods and drugs. It cannot be said that the Acts are on the whole administered in the best manner, or that they are such as to safeguard the public to the fullest extent. Moreover, there is no doubt that considerable chemical and legal knowledge is at times made use of by those who desire to evade the law. Much of the adulteration of food as now practised is of a very subtle kind, and only to be detected with difficulty, and the public analyst has not the same advantage as the author of the modern detective novel—his part is only to detect adulteration analytically; he has no opportunity of being present at the synthesis of the sophisticated food or drug. On the other hand, it must be remembered that the use of new food products under names which are not misleading may be a legitimate outcome of a wider knowledge of the properties of materials.

The public analyst to-day must, if he is to do his work well, be possessed of chemical and microscopical attainments of a high order. A wider field for investigation is open to the man who would place the examination of many familiar foods in a position of unassailable certainty by means of processes based on sound premises, and not so tedious as to be beyond the scope of an ordinary, and, I may add, not very highly remunerated analytical practice.

A summary of these appointments shows how they are distributed in the United Kingdom:—

SUMMARY OF PUBLIC ANALYST APPOINTMENTS.

	Number of Appointments.	Number of Analysts.
England and Wales . . .	232	104
Scotland	238	17
Ireland	45	7
	515	128

NUMBER OF APPOINTMENTS.

England and Wales.

61 Administrative Counties.
29 Metropolitan Boroughs (including the City of London).
144 other Boroughs.
234

Scotland.	*Ireland.*
33 Counties.	33 Counties.
205 Burghs.	13 Boroughs.
238	46

Details of the samples examined from 1901 to 1910 are taken from the reports of the Local Government Board:—

	Total Number of Samples.	Milk.	Butter.	Drugs.	Head of Population.	Percentage reported against.
1901 . .	67,841	26,143	11,938	2,301	471	8·8
1902 . .	72,321	29,452	13,387	2,353	450	8·7
1903 . .	78,077	33,090	13,766	2,718	417	7·9
1904 . .	84,678	34,413	15,124	3,244	384	8·5
1905 . .	86,182	39,341	16,287	3,232	377	8·2
1906 . .	90,504	42,335	16,991	2,726	359	9·3
1907 . .	93,716	44,364	18,176	4,024	347	8·1
1908 . .	95,664	45,093	20,729	3,289	340	8·5
1909 . .	98,544	46,678	21,134	3,347	330	7·5
1910 . .	100,749	47,895	20,742	3,084	323	8·2

The percentage of adulteration from the same source in quinquennia :—

1877–1881.	1882–1886.	1887–1891.
16·2	13·9	11·7
1892–1896.	**1897–1901.**	**1902–1906.**
10·6	9·0	8·5

It will be seen that the number of samples examined is slowly increasing, and that the percentage of adulteration detected is decreasing.

(4) An Act closely connected with those regulating the food of man is that which empowers the authorities of counties and county boroughs to control the sales of food for the lower animals, and for plants, viz., the Fertilisers and Feeding Stuffs Act, 1906, which replaces one passed in 1893. This Act, although in its details far from an ideal measure, has, without doubt, very greatly reduced the gross fraud which at one time was practised on the agricultural and, through them, on the general population. Although it would appear at first to be a measure of rural rather than urban importance, it must be remembered that a great many sales of the materials take place in towns.

The official agricultural analysts appointed under this Act must not only be capable of performing analyses by the methods which are prescribed for them by the Board of Agriculture and Fisheries, but should have a good microscopical knowledge of the various grains and seeds used for the preparation of cattle and poultry foods and of their adulterants. In addition, a real knowledge of the feeding or toxic properties of substances is necessary in order to enable analysts to certify whether foods contain worthless or deleterious ingredients. A case which recently attracted some attention in Parliament, as well as in a court of law, will illustrate this class of problem. The question at issue was as to whether hydrolysed sawdust should be considered as worthless or not. Great diversity of opinion was expressed.

There is no doubt a growing tendency on the part of public bodies which confer their statutory appointments, of the kind indicated above, on private practitioners, to consult them on the administration of the statutes and on new legislation, but it is not always realised that the advice given can, like legal or medical advice, be recognised in a tangible, even if not altogether adequate manner, by a suitable honorarium. Of course, public bodies appointing whole-time officers at reasonable salaries have a right to the best professional services of these officers, but the private analyst holding public appointments is not always well treated.

(ii.) Some of the statutory duties of public bodies can only be carried out continuously in an efficient manner when the services of a chemist are available, since the operations involved are either directly connected with chemical change or the materials concerned are such as can be most suitably examined by chemical means.

If it were possible rapidly to convey sewage from a district without considering its effect on the locality to which it was taken, sewage disposal would be purely, as it is largely, an engineering question. Since it is necessary to effect great changes in its chemical nature before it can be allowed to escape beyond control and ultimately perhaps to mingle with the water-supply, the problem is obviously one in the solution of which the chemist should take a part. Local circumstances will tend to indicate whether a system of chemical* or bacterial treatment shall be adopted. In the latter case, the purification effected naturally by bacteria and other organisms is so accelerated by a more or less artificial encouragement of their growth that it suffices for practical treatment of sewage on the large scale. The need for the chemist does not cease with the inception and successful starting of a scheme any more than that for the medical man does when he has safely introduced an infant to its sphere of future activity. Sewage purification cannot be relied upon to be entirely automatic, but the quality of the raw sewage and of the final effluent must be watched by means of chemical analysis, and possibly, from time to time, suitable modifications of the original scheme must be devised to meet the special difficulties which may arise.

The regulation of offensive trades and other matters affecting the public health, and the administration of other services of control, frequently call for the aid of the chemical expert as a consultant or as an analyst.

(iii.) In many matters normally connected with the executive work of local government, the services of a chemist, although perhaps not obviously needful, are required if the highest efficiency consistent with economy is to be reached. For example, the various residential institutions, educational, curative, preventive or protective, are frequently extra-mural, and in such cases are more or less self-contained with their own sewage works, gas or electricity works, and water-supply. In any case, large quantities

* That is, treatment *with* chemicals. Bacterial treatment is, in a true sense, chemical.

Hosted by Google

of foods, cleansing materials, textile goods, oils, paints and other engineers' stores and fuel, are purchased annually, probably at very low contract prices. Systematic chemical examination of these materials is in many cases the best, sometimes the only means of securing that the goods supplied are of the required quality and at the same time allowing freedom of contract. The careful framing of specifications for goods, not necessarily the best obtainable, but of useful quality, and such as can be economically produced in the ordinary course of industry, is a matter which calls for the best abilities of the chemist. It is advantageous for a control exercised independently of the officers actually using the goods—although, of course, by no means antagonistic to them—to be available. Of this I will speak later.

(iv.) The growth of municipal enterprise, particularly in such directions as the supply of water, light, power, and the provision of means of locomotion, has increased greatly during the last decade. The question of the relative advantages of municipal and private undertakings is not one on which views are unanimous, but it will be agreed that when such services are undertaken by public bodies, the highest efficiency—including economy of administration—should be sought. Such efficiency is in many cases promoted by the aid of a chemical examination of the materials used in the necessary works, by advice as to the best materials for special purposes, and on the cause of failure of materials. In the case of supplies of water or gas, a systematic examination of the products supplied by, as well as to, the undertaking is required. Few who are not engaged in such work will realise the great variety of goods used, in many cases without any adequate guarantee of quality. Many problems, involving much more than mere routine examination, and not always easy of solution, frequently arise.

It may be asked, in fact it is frequently asked, is not the proof of the pudding in the eating, and can the fitness of materials required for a great variety of purposes be determined by a person who handles them on an almost microscopical scale, and who, in many cases, is altogether incapable of using them practically? I think we all have seen many puddings which we would willingly prove in any possible way before taking the risk of eating them, and we are all aware that inferior and defective articles of every kind are offered for use and are used with most unfortunate results. "It follows," therefore, "that in questions of difficulty, or such as are thought so, where more satisfactory evidence cannot be had or is not seen: if the result of examination be, that there appears upon the whole, any the lowest presumption on one side and none on the other, or greater presumption on one side, though in the lowest degree greater, this determines the question, even in matters of speculation; *and in matters of practice, will lay us under an absolute and formal obligation, in point of prudence and of interest to act upon that presumption of low probability*, though it be so low as to leave the mind in very great doubt which is the truth."*

This quotation from an eighteenth-century writer fairly illustrates the very weakest ground on which the report of an expert of any kind rests, a sufficient ground to decide any action when all other determining factors are equally balanced.

I think that the function of the consulting chemist, as distinguished from a mere analyst, is so to approximate his methods of testing substances used in arts, manufactures and commerce to the conditions of their use, and to base his interpretations of analyses, or other examinations, on sound *a priori* grounds or on the results of assured experience that his reports on the relatively rapid examination of small quantities may, with the highest degree of probability, anticipate the behaviour of such substances when actually used on the large scale. This is by no means always easy, and, at times, the probability is not much higher than is supposed in the above quotation. But, since in all things probability is the guide of life, it may be claimed that the report of the consulting chemist is frequently the best, most impartial, and least costly determining factor.

In addition to all the more or less constant and regular demands for chemical assistance to the modern municipality, public bodies at times when engaged in litigation, or in promoting or opposing legislation, seek advice and require evidence to be given on their behalf on questions of chemistry as applied to industry or other matters of general importance. How is advice and assistance of the various kinds indicated to be obtained?

II.

That public bodies should in any branch of their service secure the best man available none will deny. How to obtain such a man is a less easy matter to decide.

In chemical, as in all other public services, the question of the whole-time officer *versus* the

* Introduction to Butler's "Analogy."

Hosted by Google

outside expert must be considered. The late President of the Society of Public Analysts, speaking more particularly of this class of officers, said in his retiring address:—"The system of county authorities appointing a 'whole-time' officer for carrying out the work required by them is one which . . . has 'come to stay,' and it cannot be denied that there is a good deal to be said in its favour if carried out on proper lines. But the establishment of a municipal or county laboratory at the expense of the ratepayer on the lines of a municipal trading concern is highly objectionable." This quotation expresses very fairly the feeling of the best class of private practitioners. I think both systems have their advantages, and while this remains so we shall see both systems side by side. It is the man who is merely an analyst who will feel most hardly the growth of the "whole-time" system. The man in practice who is really an expert on any subject of public utility, will find that his special knowledge enables him to hold his own as a private practitioner.

How are we to find a man with the desired qualifications?

It was realised in 1885 "That the profession of analytical and consulting chemistry is one of great importance to the public, and, having regard to the rapidly-increasing application of chemistry to legal investigations, to public health, to the adulteration of food, to agriculture, and to the arts and manufactures, it is desirable, that persons practising the profession of analytical and consulting chemistry should have both a practical and scientific knowledge thereof.

"That it is a matter of increasing importance to Government Departments, corporate bodies, and others requiring the assistance of persons competent to practise in analytical chemistry and to advise in technological chemistry, that such persons should be properly trained and that their qualifications should be attested by certificates of competency granted by a scientific body possessing sufficient status," and that at the time there was no such body in existence.

The result of this feeling was that a charter, the preamble of which I have just quoted, was granted to the Institute of Chemistry, a body which had been founded some eight years earlier. This is the only body which grants a certificate which can be considered as attesting the required qualifications, and it is recognised as such by most of the various appointing or confirming authorities. It obviously cannot confer on, or to more than a limited extent require of, its members, experience, which can only be acquired slowly and painfully. It is, however, a great deal for it to attest real competency, even if not always of a mature kind.

The municipal chemist must be able to take a sympathetic interest in chemical industry and to give practical advice to his authority when it comes in contact with industry. He must look on industry as a thing to be encouraged as well as controlled. A member of the Society of which our Chairman is President, has no excuse for being ignorant of industry, even although he himself may have no direct connection with it.

The municipal chemist, more especially the "whole-time" man in a relatively comfortable appointment, must read, think and experiment, and should feel that his education—ever progressing—had hardly started when he finished his formal scholastic course, that then he had certainly learnt the names of his tools, and had some idea of their uses, but that he must continually strive to become more expert with them. It is, I need hardly say, an unfortunate thing for the municipality, the man, and the profession, if a raw fledgling obtains an independent appointment. It is difficult for such a man to magnify his office. Fortunately the contingency is of rare occurrence.

It is not always possible or desirable for one man to perform the whole chemical work of a municipality, and, on the other hand, some bodies have not enough work to occupy the time of one official or could not sufficiently remunerate a man of experience adequate even for their normal requirements. Here the natural division between the fields of action proper to the departmental and the external systems is indicated.

Large public bodies, having a great variety of duties and undertakings, in most cases have adopted the departmental system. A good all-round man, possessing special knowledge, with a graded series of subordinate officers, will be able to conduct all the work normally arising, and he will probably feel able to take a holiday without suffering much uneasiness. The need for economy of effort will tend to some specialisation on the part of subordinates, some of whom, in consequence, may develop into mere but useful routine workers highly skilled in certain classes of work. The more enterprising and mentally industrious will develop real specialist knowledge. Every good chemical department is an educational establishment, and its records form a dictionary of applied chemistry which is continually being re-edited and brought up to

Hosted by Google

date. The external expert will from time to time need to be consulted, and the ripe knowledge of the head of the department will indicate who should be consulted—a most useful service, since obviously a man's willingness to give advice is no certain measure of his knowledge. Smaller bodies do the same thing as the larger, but on a less ambitious scale; but still the chief can take a holiday with safety. He will, however, be likely more frequently to need the co-operation of the outside expert than the man in the larger town.

Unless a public body can afford to pay a good man with a fairly good man under him, it will probably do wisely to appoint a private practitioner as public analyst, preferably one with a laboratory in the district—but this cannot in reason always be—and to arrange with him to undertake its general analytical work, to advise them or to put them in touch with more specialised knowledge than his own. It is clearly to the advantage of an authority with but little work requiring chemical aid to make use of the abilities and knowledge of a private practitioner, who can in this way give them the fruit of a much more varied experience than they could otherwise command.

The training of chemists up to the stage of B.Sc., or the Intermediate examination of the Institute of Chemistry, is properly a matter for the colleges to look to. I think these institutions should keep in view their proper functions in regard to the training of the consulting and analytical chemist. If they turn out men well-grounded in the *principles* of the science of analytical chemistry and the *methods* of chemical analysis, and generally well educated, having a fair knowledge of mathematics and physics, who can think clearly and express their meaning in their own language, they have done a great work; accurate observation, exact and directed experiment and clear thought form the basis of all scientific progress. The *application* of the principles and methods of analysis is best studied in a laboratory where it is one of the serious businesses of life, and where the problems to be solved are real ones to which an answer is imperatively demanded. Immature specialisation is thus avoided. It is a hopeful sign that evening advanced courses on special subjects of applied chemistry are being given, at least in the Metropolis, by men who are working daily at such subjects.

I have tried to indicate the advantages to the public service of chemical assistance. In doing so, I have endeavoured to face continually the fact that the general public is not yet enthusiastically convinced of the need for such assistance, and that they will be persuaded to this conviction only by evidence of the utility and even the necessity of the chemist's services in conserving the resources of this very limited planet.

DISCUSSION.

THE CHAIRMAN (Dr. Rudolph Messel), in opening the discussion, said that the work done in municipal laboratories required the highest skill of the scientific man. For instance, in regard to gas, he had to make tests not only with regard to its chemical qualities, but its calorific power, and he had to carry out similar duties in relation to petroleum and such-like materials. With reference to the Food and Drugs Act, it was most satisfactory to notice, that, notwithstanding the increased number of samples taken, the percentage of adulterated material was less. It was astounding that so small a staff should be considered sufficient to do all the work that was now demanded from analysts, especially considering how particular the people of the country were with regard to their food products. The author had also referred to the work done under the Fertilisers Act, which had undoubtedly been a means of great good. In his concluding remarks Mr. Coste had mentioned the lack of enthusiasm shown by the general public on the subject, but that, perhaps, was not surprising when sewers were concerned. The author had inquired who was the best man to undertake the various classes of work referred to in the paper. Personally, he thought it was essential to have a man who had a thorough scientific education to begin with, and that he should then gain such experience in life as was necessary in every kind of industry. Not only was a thoroughly competent man required inside the department, but it was also advisable to seek outside advice from people who had experience of a much wider field of operations.

COLONEL CHARLES E. CASSAL said he was pleased to find the paper contained a number of expressions of pious hope, which he trusted would meet with realisation in the future. The author very properly desired the public to understand that a man who held the position of a municipal chemist should not only be a highly-trained man, but must possess such personal characteristics as would enable him to be looked upon as absolutely reliable. He agreed with the author that it was not always easy to find an Admirable Crichton capable of filling a post of that kind with credit to himself and advantage to the public. Part of the difficulty lay in the fact that the English system of scientific education was only of yesterday; that it required great development and great improvement; and especially in chemistry it was by no means as yet clear to those who were the leaders on the question of chemical education which

Hosted by Google

was the best course to take to train a man to fit him for the particular kinds of work to which reference had been made. Another extremely interesting point was the question of the treatment of those Admirable Crichtons when they were found. He did not hesitate to say that the usual treatment accorded by most public authorities to such professional officers was abominably bad; it was, in point of fact, in most cases disgraceful. There was a greater tendency nowadays to "skin" the professional man than there had been in the past, and that tendency seemed to be increasing considerably. The municipalities of this country did not yet understand any more than the public at large understood that it was essential, if they wanted good work and sound advice, that they must employ a good man and pay him adequately, as every other decent professional man was paid. His experience lay more in the direction of public analytical work, and he did not hesitate to say that the general treatment of public analysts was a disgrace to the country. Two examples had recently occurred of the sort of thing which certain municipal bodies did when they appointed an officer of that kind. The Borough Councils of Wandsworth and Lambeth recently advertised that the appointments of public analysts for their districts were vacant, and had placed the rate of remuneration for those officers at absolutely the lowest point that had ever been suggested. How was it to be expected that self-respecting men, to say nothing of qualified men, would accept posts of such importance upon terms of that kind? The Council of the Institute of Chemistry very properly called upon its Fellows and Associates, if they had offered themselves as candidates for those posts, to withdraw their applications, and he was pleased to say that, with two exceptions, all the candidates did so, leaving the two local authorities with a couple of candidates apiece. Such things ought not to be, and the central authority which was concerned with the matter should prevent them. It ought to be the duty of the central authority to see that the proper man for the post was adequately paid, and to refuse, as they had the power to refuse, to sanction appointments made upon such bases. One point upon which the author had not touched was that if his desires were ever to be realised; if county councils and the municipal authorities of London were to be properly served, one of the first things that must be done was that the central authority controlling all the local bodies should insist that the right man was appointed; that he had certain specified qualifications; and that he should be paid at such rates that he was not compelled by necessity to do bad work. With regard to the question of the Food and Drugs Acts, this country was behind every civilised country in the world in their administration. In a paper he had the honour of reading in that room not very long ago, he pointed out that, compared even with some of the younger colonies, the United States, France, and Germany, Great Britain was a long way behind the proper administrative position that it ought to hold as the country which first initiated laws directed against adulteration. It was ridiculous that the present system should continue to exist. The central authorities were concerned apparently with the general administration of the Food and Drugs Acts, the Fertilisers and Feeding Stuffs Act, and various other Acts, but the officers of the central authorities apparently had not power to insist upon adequate and effective administration of those Acts. Recently a large vinegar brewing association applied to the Local Government Board with regard to the question of the adulteration of vinegar, and that Government department replied that they had no power to deal with the matter; and they confined themselves to the expression of the opinion that vinegar ought to be so and so, that malt vinegar ought to be so and so, and that the standard of acetic acid should be so and so. But that was of no use to a public authority. It was of no use for their officials to go into court and prosecute on a mere expression of opinion or of the hope of a Government Department. It was necessary that some definite regulations should be laid down which had the force of law, and without that it was perfectly useless to disseminate a mere expression of pious hopes and opinions. His remarks applied not only to that particular question but to the Fertilisers and Feeding Stuffs Act, which was a dead letter. It was so hedged about with complications and with the necessity for applying to the central authority to move one's little finger, that it was absolutely useless as a Preventive Act throughout the country. In order that the author's desires might be carried some day into effect, he would like to see, in the first place, some competent central court or authority established, composed of experts who understood the different subjects which had to be dealt with, which could act as a sort of directing court of reference in regard to all matters of that kind. Instead of having to fight a variety of complicated questions in courts of law, before an ignorant magistrate with ignorant counsel, the law ought to be laid down in such a way that there could be no question as to what should be done. He trusted that the officers the author desired to see would some day be appointed, and especially that they should be of the type he referred to, and above all that they should receive emoluments worthy of their office, and not the sort of payment which was doled out to a second-rate sanitary inspector or a broken-down police constable. Whatever might be arrived at in the future, the present condition of things in regard to municipal chemistry was abominably bad from one end of the country to the other, and required thorough reform.

Mr. Walter F. Reid thought the paper clearly illustrated that it was requisite for the municipal chemist to know a very great number of things besides chemistry. It was absolutely essential that he should have a knowledge of the laws bearing

Hosted by Google

on the subject, but that was unfortunately a part of the education of the chemist which was generally neglected. When he came from his training college he had to make himself acquainted with a large amount of legislation of which he had been previously ignorant. He agreed with the author that it was futile to place a novice, or one who had just passed a very brilliant chemical examination, in an official position where he was one of the most important administrators of Acts of Parliament. Colonel Cassal seemed to think that the position of this country with regard to adulteration was inferior to the position in foreign countries. Personally he was not quite sure whether the public in this country would put up with the position as it existed in some foreign countries. For instance, he was quite sure there would be an outcry amongst some very great industries if the Bavarian law with regard to the adulteration of beer were to be introduced. If a manufacturer put into his beer articles that were used in the vast majority of breweries in this country, he would forthwith be haled off to prison. He remembered some years ago, when some English chemists were over in Paris they were received in the first instance by the President of the Paris Municipal Council, and in the second place by the Prefect of Police. Some of the English chemists could not quite understand why they were welcomed by the Prefect of Police, but he justified his position most clearly when he said that the bulk of the convictions obtained in Paris for infractions of the law were only rendered possible by the services of the chemists. That was a view that the public authorities in this country hardly took up; they did not attribute to the chemist the importance that really attached to his office. If the cases in the criminal court were carefully followed it would be found that year after year the convictions in perhaps the majority of cases were obtained owing to the assistance rendered by a chemist. For instance, to mention one of the most recent murder trials, the Seddon case, where would the authorities have been without the assistance of a very expert chemist, who must have had a very long training to do the work he did? With regard to the question of pure food, he thought this country was not in a very backward position, but the position it occupied, and the great advance which had been made, was due to the care and supervision exercised by the public analysts. Unless the duties were carried out with the greatest conscientiousness, the examination of samples would be perfunctorily undertaken, but he had rarely heard of a case where an instance of adulteration had escaped the detection of the analyst, and that was the more wonderful because, from the very nature of the case, the public analyst had very little opportunity of coming into contact with the industries the products of which he had to examine. One passage in the paper which had struck him very much was the statement that evening classes were held, especially in large towns, by those who were in actual practice in different industries. That kind of tuition was, he thought, of the very greatest importance to those who were carrying out public functions as chemists, because unless one was actually in contact with the industries it was impossible to keep up to date and find out what the tricks were which might be played upon the public. It had been said that wherever a chemist found out adulteration there was always some other chemist ready to mask it or disguise it. That, undoubtedly, was the case. People would always be found who would prostitute the science they possessed to deceiving their fellow beings, and that could only be met by increased skill and ability on the part of those who had to produce articles. The point he emphasised was that there should be some contact between those who were testing the products and those who were making them in some way. Public analysts were always to the fore whenever any opportunity was given them to visit factories and gain technical information. The author had not touched upon the question of the application of chemical knowledge to the materials which were used in large cities in order to prevent the mis-applied efforts that were now made in so many cases. An exhibition in connection with smoke abatement had recently been held, and some excellent papers had been read on the effect of the atmosphere on building materials. There was a great want of supervision in London with regard to the materials used. Hundreds and thousands of pounds had been subscribed for different monuments, but the very distinguished gentlemen who formed the committees never seemed to get advice from a competent person as to the materials of which the monument should be made. For instance, a monument was erected of beautiful Carrara marble, and on the top of it was placed a so-called bronze statue, and the marble quickly became defaced. Why the committees which received subscriptions for public monuments did not ask for a little technical advice on such matters he did not know. He hoped nobody would ever subscribe a single penny towards the putting up of a bronze statue on the top of a marble pedestal in London. The authorities in Liverpool were much wiser; they used a beautiful red granite for the base of their statues, and thereby prevented the miserable discoloration that was obtained in the cases to which he had referred. One point raised by the author was the restrictions which were placed upon certain industries. He believed Mr. Coste was of the opinion that those restrictions should not be too hard and fast. For instance, let them take the restriction imposed on the use of petroleum. Before motors came in restrictions were placed on petroleum spirit—and perhaps, rightly so—because there were a great many accidents; but those restrictions were found to be very hard indeed when the new motor industry commenced, and had to be modified. Similar restrictions were placed on carbide of calcium. Such restrictions were too strict in many cases, the conditions imposed being unnecessary, as

Hosted by Google

they had the effect of impeding a rising industry. He had heard that restrictions had been sought to be imposed by a Government authority on one of the most important fertilisers now being produced. The restriction was not necessary, and if it was imposed it would have a very bad effect upon British agriculture. With regard to the question of water-supply a promise had been obtained from Mr. Burns that a water board should be established throughout the whole country which would take cognisance of everything relating to water-supply. Such a board would, he thought, be an excellent thing for the unification of methods, because an enormous amount of money was wasted on litigation over points that might easily be settled. If the conditions with regard to sewage were made too rigid all progress would be stopped. The treatment of sewage at the present time was the exact reversal of what was considered the proper practice formerly. Then all fermentation or putrefaction was stopped, but the present idea was to encourage it to the utmost. Colonel Cassal was rightly indignant about the position technical chemists held, but public analysts were themselves partly to blame in the matter, because the author's figures showed very clearly that a number of them were pluralists to a most exaggerated extent. There must be a number of well-educated men trying to get appointments, and if they could not secure them in any other way they would undertake to do the work for less than they would otherwise accept if the work were better distributed.

Mr. E. Grant Hooper endorsed the remark of the previous speaker that there was a great amount of ignorance on the part of the public in general and on the part of a number of educated people, who should know better as to what chemistry really was. But personally he deprecated the author's use of the term analytical as distinct from what he called a chemical examination. He wished to remove completely from the minds of everybody the impression that an analytical operation was of the nature of a mechanical one. It was nothing of the kind. Every efficiently carried out analysis was an investigation which would be more or less elaborate according to the particular circumstances involved and the amount of money which could be spent upon it. Dealing with the question of ignorance, when a manufacturer wanted what he called a chemist, he went only too frequently to a professor, who also only too frequently undertook to supply him with a chemist in a large number of cases at £50 a year or less. To his mind, when the professor's assistance was sought in that way he should reply that he could not supply a chemist, but a well-educated chemical student. Experience in chemistry was of the utmost importance, and the very first thing that municipalities should require was training, and, secondly, experience. He would in no case permit a man to undertake responsible duties who had not obtained experience. When some trouble arose in the works, the manufacturer went to the young man to whom he was paying such an inadequate salary and expected his knowledge to be almost world-wide. Such knowledge could not be obtained without experience, and consequently a competent chemist had a width of knowledge such as very few other professional men possessed, because he could only gain it by the widest reading and study. The paper would be most valuable if it only directed the attention of the public to what chemistry really was and how much they were indebted to the chemist. Every day the chemist became more and more important. Every time a purchaser demanded quality when purchasing, he tended to insist upon the manufacturer having skilled assistance in his works, and the sooner every manufacturer on a large scale appreciated that advantage the better would his experience be in the way of profit, and the better would it be for the community at large. He had between thirty and forty years' experience of the purchase of very varied compounds, and one of the largest buyers told him on one occasion that the prices of the commodities had been reduced as the result of the advantage obtained by going to trained chemists by one-third. Large buyers found that they could, as the result of legitimate competition, get a reduction in the price of their articles equal to at least one-third. If the public realised what good chemists were capable of doing them he thought it might be hoped that the complaint Colonel Cassal had made as to the payment they at present received would be remedied, and that the chemist in the future would reap his just reward.

Mr. Noel Heaton said the author had drawn a distinction between the consulting chemist and the mere analyst, but in modern work the chemist had to be a great deal more than a mere analyst. He had to tackle all sorts of problems, and had to have resource not only to chemistry, but all the allied sciences, in order to cope with the great amount of science which was applied on the part of the manufacturers in devising methods of adulteration that the chemist could not detect. The result was, as Colonel Cassal had said, that the chemist of the present day whose duty it was to protect the public had to be a very widely-read man, and it was therefore vitally necessary he should be treated as a professional man and paid as such. He was afraid, however, it was almost too much to hope that he would be paid on the same generous scale as a legal man. He endorsed previous speakers' remarks that it was time the public were enlightened as to what the problems of the chemist were. There was extraordinary ignorance on the part of the public in this respect. It was quite a daily experience for people to bring him bits of plaster and things of that sort with the suggestion he should analyse them and tell them the next day what they were composed of. A friend of his once had a bottle of wine brought to him with the request that he would analyse the contents, and that the analysis should be sent back with the bottle of wine, which

Hosted by Google

was required for dinner. The reason the chemist was not well paid was, he thought, because people believed he was a perfect genius, and was therefore able to feed himself without the necessity of having money to pay for the food. He endorsed what Mr. Reid had said with regard to the absence of control by the chemist in the various public monuments which were erected. Personally, he had been consulted that week in regard to a public work which was erected at great cost some years ago. Large sums of money had been spent on restoring it on two or three occasions, and as a last resource the people thought they would spend a guinea or two in getting expert advice from a chemist to put the thing right.

Mr. J. H. Coste, in reply, said he was very pleased to find there were so many points of agreement between "The Champion of Pure Food," as he thought he might call Colonel Cassal, and himself. If the Fertilisers and Feeding Stuffs Act had not prevented adulteration, undoubtedly adulteration had ceased to a large extent since the first Act was passed. The two things might have gone on collaterally without any real connection, but it was a fact that grossly adulterated linseed cake, for example, was not in existence now. That might, of course, be due to other causes than the very clumsy Acts that had been passed to deal with those matters. Colonel Cassal's suggestion of a court of reference was an extremely good one; something of that kind was undoubtedly required. He had a very vivid recollection of listening to cases in the police court where the magistrate had hardly any idea of what the point at issue was, and thoroughly disliked dealing with the cases, which stopped the ordinary course of petty justice, and generally were a nuisance to everyone. Colonel Cassal had referred to the way in which the food laws were administered in other countries. So far as Germany was concerned, he believed there were four kinds of meat—home-killed, a very fair sort of meat, and two very nasty kinds, one consisting of the flesh of animals who had died of tuberculosis, the flesh being sterilised for sale to the poor. He thought everyone present would rather analyse such meat than consume it. In reply to Mr. Reid's remarks, he thought a chemist who had to work for a public body must be somewhat of a lawyer and a good deal of a diplomatist. He must not only understand chemistry but endeavour to understand men, and to know what was possible in a world of this kind. He agreed with Mr. Reid as to the unsuitability of the materials used in London for monuments. If any kind person wished to put up a monument to him (Mr. Coste), he advised the use of either lead or platinum for the statue—lead, perhaps, would be the more modest material—and quartz for the base, because nearly everything used in London had to withstand the action of sulphuric acid. The question raised with regard to restrictions on industry was a difficult one. Personally he thought that the reasonable municipal or Government chemist would always feel that the rates and taxes were paid very largely by the people who ran big industries, and therefore that the restrictions and control should not be of a harassing and petty nature. Mr. Hooper's remarks with regard to chemical students were altogether admirable. It was most unfair to expect quite a young man fresh from college to have a great deal of experience, and, for £60 or £100 a year, to know everything. In fact, he did not. Mr. Heaton had referred to the "mere analyst." He (the author) had to use that expression, although it was one he did not like, as he was very strongly of opinion that the "mere analyst" should not exist in an independent capacity; he was really in the larval state. The only justification for the "mere analyst" was that he was young, or that he was a man whose early training was very much neglected, or that he was a man of very limited abilities. Mr. Heaton had also stated that he hardly dared to look forward to the day when the chemist would be paid as well as the legal expert. He was glad to say that had already happened, because he knew of a case where the fee given to the chemical expert was as high as that given to a very eminent counsel, who was now one of his Majesty's judges. But it was very often forgotten that a chemist was an ordinary man; that he lived by food, and that his science had not at present arrived at such a stage that he could separate proteins from the nitrogen of the air and live in that way. He did not wish to make the paper a means of touting for better pay for the profession, but the saying was just as true of the chemist as of the collier—that the labourer was worthy of his hire; and he really thought he should try and see that he got it.

On the motion of the Chairman, a hearty vote of thanks was accorded to Mr. Coste for his interesting paper, and the meeting terminated.

ORIENTAL CHROMOSYMBOLISM.

In a recent Note in our *Journal* on the Hindu *svastikas*, besides giving the colours of the right-handed svastika, golden, or red, and of the left-handed, silvern, or blue, green, black, or white, I gave the Hindu colours of the four conventional "quarters" ["corners," "wings," "skirts"] of the Earth and the Heavens, as they in due order wave over "the Seven Seas" between London and Melbourne, and Shanghai, in the distinguishing flag of the Peninsular and Oriental Steam Navigation Company; and this has brought me into so much instructive correspondence with various gentlemen engaged in trade with the East, and solicitous to use attractive "trade-marks" in its promotion, that I feel it will be of general interest to place on public record, in our *Journal*, all that I have written in reply to one and another of these private inquirers on the subject; and I confine myself to

Hosted by Google

the Eastern significances of "colours,"—using the word in its popular meaning,—and say little or nothing of the Western, save by way of casual comparisons and contrasts, as we are all more or less familiar with that division, geographical, chronological, and ritualistic, of the theme. I gave the colours as I found them in use in India:—E, red; S, yellow; W, blue; and N, white or black. But they vary from this order in books. In Monier Williams, the order is:—E, white; S, yellow; W, blue; and N, red. In the "Chandrogya Upanishad":—E, red; S, white; W, blue; and N, black; and in the "Vedanta Paribasha," as I am told:—E, yellow; S, red; W, blue; N, white. The Chinese symbols of the four "quarters" are:—E, "the White Tiger"; S, "the Red Bird"; W, "the Blue Dragon"; and N, "the Black Warrior." The Hebrew names, or, at least, one set of them, of the four "quarters," have the same meaning as the names given them by the Hindu worshippers of the rising sun; that is "front" for E; "right-hand" for S; "back" for W; and "left-hand" for N; but I have never been able to get trace of any ritualistic colours for these "quarters," either in Israel, or in Islam.

The colours of "the Seven Planets," "the Eyes of the Lord, which run to and fro through the whole Earth" [Zechariah iv. 10] are, according to the Hindus:—

Planets.		Colours.
Saturn	*Sani*	Black
Jupiter	*Brishpati*	Orange
Mars	*Mangalá*	Red
Sol	*Surya*	Gold or yellow
Venus	*Sukra*	White
Mercury	*Budh*	Yellow
Luna	*Chandra*	Jasmin white

The Babylonian colouring of the planets was nearly the same, the only differences in it being that of Jupiter, purple, and of Mercury, blue. The "gems" of the Hindu amulet, the *Nava Ratna*, or "Nine Gems," that is, of "the Seven Planets," with the waxing, full, and waning Moon counted as three [compare "the triple Hecate"], are as given in the table in next column [the Persian and the Polish "gems" of the planets being given in parallel columns with them, for the sake of the suggestive agreements and disagreements between them]. This is the first time of these three sets of planetary "gems" being compared, and note, *passim*, that Katu, the Hindu name of the waning Moon, is, probably, the true source of the English name of "the Cat's-eye" of Malabar and Ceylon.

It is the "astrobolos" ["planet-stricken"] of Pliny, xxxvii. 50 (9), and, again, his "Oculus Beli" [Eye of Belus], xxxvii. 50 (10). The "Portugals" when they first reached India would have at once heard of the god Katu, and they well knew of Pliny's "Oculus Beli," and hearing also the cat everywhere in India called *beli*, they would readily give the stone the name of *Olho de gato;* and thence named by the French *œil de chat*, and by us "Cat's-eye." In Afghanistan the cat is called *pusha*, and in Southern India *pusi*, our "puss" and "pussy"; and as this name has been conjectured to be that of the Egyptian goddess Pasht, to whom the cat was sacred, and in whose worship through two millenniums it was already civilised before it was passed on into Greece and Italy, it is not impossible that its name of *beli* also was derived from that of the god Belus of Babylonia, who, according to the Greeks, was the son of Poseidon and Lybia, and the father of Ægyptus, and that it was with the cat itself transmitted from Mesopotamia into Western India, and thence overran all India. If so, if this etymology (which "Bells the Cat" ages before Archibald Douglas!) is as true as it is plausible, the harmless, half-human creature that Henriette Ronner has made in itself almost seraphic, by its three names of *puss*, *beli*, and *cat*, recalls with strange emotion the three great historical pagan religions of Chaldæa, afterwards Babylonia, and Egypt, and India.

Planets.	"Gems."		
	Hindu.	Persian.	Polish.
Saturn	Sapphire	Sapphire	Turquoise
Jupiter	Topaz	Carnelian	Carnelian
Mars	Coral	Bloodstone	Emerald
Sol	Ruby	Topaz	Diamond
Venus	Diamond	Amethyst	Amethyst
Mercury	Emerald	Touchstone	Loadstone
Rahu, waxing Moon	Moonstone	—	—
Luna	Pearl	Crystal	Crystal
Katu, waning Moon	Cat's-eye	—	—

Sarendranath Mohun Tagore sent to the Oriental Congress [Dr. Leitner's] of 1891, a collection of rings set with *white* stones for Brahmans, *red* for Kshatryas, *yellow* for Husbandmen [*ryots*], and *blue* for Merchants and Thieves. In India *red* is the colour of solemn *joy*, and of sovereign might and right, and of all reverencies; and is always worn by the Hindu women at marriages. It is also the bridal colour of China. *Yellow* is the Hindu colour of domestic and social *gladness*, and festivity, and is also worn at weddings, at least in Western India.

Among the Bretons it is the colour of mourning. *Blue*, often confused with *green* and *black*, is

Hosted by Google

unlucky; notwithstanding that it is the colour of the merry-hearted god Krishna, whose very name means "black." Only the Sikhs in India wear blue turbans, and no Hindu will wear a blue turban; and no Hindu, Muslim, or Parsi, will complete the purchase of a sapphire until after he, or she, has worn it for a year, to test whether meanwhile it bring them weal or woe; which explains why sapphires are, comparatively, so cheap in India. Yet the Mahratta women habitually go blue-robed. A good deal seems to depend on the tint, or on the shade, of the blue. *White* is the mourning colour of the Hindus; compare Revelation vii. 13, 14:—"What are these that are arrayed in white robes? . . . These are they that have come out of great tribulation." Blue robes are worn by all Chinese, except certain Lamaists, who robe in yellow. Among the Shiah Muslims in India, and, I presume, elsewhere, *red* signifies the death of a martyr by *bloodshed*, and *green* by *poison;* and hence *green* is the colour consecrated to al Hasan, the eldest son of Ali, the cousin-german, and adopted son, of the Prophet of God, and *red* to al Husain, his younger son. Green is worn by Muslim Emirs; and Muslims who have done the pilgrimage to Mecca are entitled to wear green turbans; and a *green crescent* on a *white* flag is the proper ensign of all orthodox Muslims, *i.e.*, Sunnis. White was the colour of the Ommiades [A.D. 661–750], black of the Abbasides [*circa* A.D. 750–1258], and green of the Fatimedes [A.D. 908–1171], except in Egypt, where their colour was red. The colours of the five great orders of Dervishes are, respectively, black, green, white, red, and blue; and you can thus at once distinguish their "prayer carpets" [*jai-nammes*, "place of prayer," *sajjadah* "(the place) of prostration,"—"of adoration,"—"of self-forgetfulness" in God]. Among the Muslims of Egypt there is no mourning colour for men; but the women when in mourning dye their shirts, and veils, and handkerchiefs, and forearms in indigo blue; and in all the countries they ruled [they really rule nowhere now but in Arabia], the Muslims compelled the Christians and Jews to wear blue robes. Yellow and green are still in all Oriental countries the favourite wear of the wise-hearted, noble women of Israel.

Of curious facts of the symbolism of colours, I can recall, without being able to give accurately chapter and verse for them, these following:—Evelyn states, somewhere [in a letter to Pepys, of 1685?] that the Greeks wrapped the Odyssey in "blew," as the colour of the sea, and of voyages by sea, and the Iliad in red, as the colour of land, and of wayfaring by land, and of warfaring. Pepys says, somewhere in his Diary, that the ropes made for the Royal Navy, in his lifetime, had a single scarlet thread spun throughout their length. In the French *Tricolor*, red stands for the Capets, blue for the Valois, and white for the Bourbons; and Colonel Roy de Lachaise—with whom I corresponded on the subject—for telling his men of the 51st Infantry Regiment, in 1903, at Beauvais, of this historical fact, was incontinently retired from active service in the French Army. Our regiment of Royal Horse Guards derives its *sobriquet* of "the Blues" from having been originally raised at Oxford; a connection with the University of the "Dark Blues" that should be kept vividly alive. Both in England and in China the volumes of the lists of Government Officials in the several Administrative Departments of the State are called "Red Books!" The *cocarde*, or "cocade" worn by the rebels and their French [Bourbon] instigators during the American "War of Independence," was most appropriately consorted of black with white. I do not know the origin of the coloured bobs of our Light Infantry regiments ["Light Bobs"] as they were uniformed in the days of my youth. The black stripes in the "*dragonne*," or sword-knot, worn by Austrian officers commemorated the loss of Jerusalem in the thirteenth century to the Holy Roman Empire. The red stripes in our English military sword-knots probably have some similar meaning, apart from the obvious one, but I have never been able to unravel it out of them.

It is hopeless now to trace in any detail all this chromosymbolism to its sources; the traditions of it, in the course of the evolution of the human races, and nationalities, having become so broken up, and confused, and darkened, and too often entirely obliterated. None of it, in its origin, is likely to have been arbitrary, and all of it was most probably perfectly natural. The French say:—

"Yeux bleus sont aux Cieux;
Yeux gris au Paradis;
Yeux noires au Purgatoire;
Yeux verts—aux Enfers!"

It is everywhere in Europe a matter of popular observation, that black hair indicates a fanatical, persecuting disposition, whether in ecclesiastics, literary men, orators, or statesmen; red hair, a quick and passionate, but generous disposition; and brown hair, a sane, and temperate, and just, and steadfast, and poetic disposition.

Again, there is the new doctrine of "Warning Colours in Nature," to which the designation of "Semantics" is being appropriated. Thus it is said that the "black and yellow" colours of wasps, and the "black and white" of porcupines warn their victims from them. Surely this is putting the cart before the horse, and I would rather say that the victims were warned by the fearsome forms of these their maleficent foes.

My own general conclusion is that the symbolism of yellow, blue, and green, has become so varied, even in the historical Old World, although inhabited, over its whole historical area and time, by one and the same race of Caucasian or Noachian men, that nothing can be done to trace it back to its beginnings, and harmonise its current confusions; that the symbolism of white and black is far less varied; and that only red has almost everywhere, and perenduringly, stood for the East, *i.e.*, "the rising sun," and for all potencies and dominations, and all glories, and majesties, and for all divinities,

Hosted by Google

from the lowliest and basest, to the highest and holiest; and justified its title of "Dominical Red." In India we owe much to its being the colour of our "Red-coats." For the full reasons of all this we have to go back to primæval hierophallic facts, and, beyond them, to deeper depths of prehistoric, nay, prehuman facts; with which, for the present purpose, I am not concerned.

In the spectrum, *the order* of the colours is violet, indigo, blue, green, yellow, orange, red. In plants *the evolution* of the colours is from green, to yellow, to red, and to blue—the perfected colour of flowers. But it means nothing apparently in chromosymbolism.

GEORGE BIRDWOOD.

THE POTATO AND BEETROOT CROPS IN FRANCE, 1911.

According to the official returns just published by the Minister of Agriculture, the potato crop in France yielded, during 1911, 11,527,900 metric tons (*viz.*, 11,346,358 English tons) from an area of 553,000 hectares (= 1,365,910 English acres), being at the average rate of 20·84 metric tons per hectare (8 tons 6 cwt. English weight). The potato crop of 1911 in France was considerably larger than that of 1910, which amounted to only 8,400,000 tons, and less than that of 1909, which was 16,700,000 tons.

With regard to beetroot, the areas cultivated, production, and yield of the various kinds grown in 1911, are shown in Table I.

The production of beetroot this year shows a considerable falling off when compared with that of the two previous years, especially as regards sugar-beet and of the kinds used for feeding cattle. This is due, in great measure, to the want of rain last summer, especially at a time when it was most needed.

To this shortage may be attributed the rise in the price of sugar, and the high prices of forage now prevailing in France.

The quantities of beetroot produced in France during the last three years are shown in Table II.

TABLE I.

	Areas Cultivated.		Quantities Produced.		Yield in	
	Hectares.	English Acres.	Metric Tons.	English Tons.	Metric Tons per Hectare.	English Tons per Acre. Tons. Cwt.

EMPIRE NOTES.

Imperial Commission of Inquiry.—The appointment of the Commission of Inquiry, which was determined upon by the Imperial Conference in 1911, marks an important advance in the movement towards closer commercial union between the Home Country and the Oversea Dominions. The wording of the resolution dealing with the subject indicates the comprehensive scope of the inquiry, which is to include—(1) the national resources of each of the Dominions and the best method of developing them, and (2) the ways by which the trade and commerce of each with the United Kingdom could be improved and extended under the fiscal conditions which prevail in each country. The membership of the Commission is representative of Canada, Australia, New Zealand, South Africa, and Newfoundland and the United Kingdom, in the proportion of one each for the separate Dominions and six, including the Chairman, for the United Kingdom. Lord Inchcape, the chairman, acted as Special Commissioner for the Government in China in 1901, and has served on a number of Government committees. Among the representatives of the Dominions is Sir Joseph Ward, until recently Prime Minister of New Zealand, whose opinions on Imperial federation are well known. The inclusion of Sir H. Rider Haggard, who has devoted considerable attention to the subject of land settlement, both at home and overseas, of Sir Edgar Vincent, who acted as financial adviser to the Egyptian Government, and in other important capacities, and of other well-known representative men, should ensure a comprehensive and suggestive report which may do much to bring the various parts of the Empire into closer union.

Canadian Railway Development.—The expansion of Canadian trade corresponds in a very large measure to that of railway extension. Railway construction has been the pioneer of Canadian industry. Each year the railway mileage has increased considerably, and still further developments are looked for in the future. In British Columbia, for instance, railways have been approved for a matter of 450 miles, and on Vancouver Island for 150 miles, besides many small branch lines to be constructed by the various railway companies who now have lines intersecting various parts of that Province. In Alberta the local government has announced its new policy, for which a guarantee of interest on contract at the rate of 20,000 dollars per mile, or a total of 13,000,000 dollars has been promised for three railway lines in the Peace River district. In connection with these three railways a considerable amount of swamp land will have to be crossed, which will necessitate a good deal of bridge-building. The opening up of this district is likely to prove extremely valuable, in view of the rich farming country which will now be brought within reach of markets. Throughout the prairie provinces minor lines are being extended in all directions.

Canadian Board of Trade.—The Boards of Trade of Canada discharge somewhat similar functions to those of British Chambers of Commerce, except that they are quasi-municipal bodies, and are therefore more completely representative of the trading community of their various localities. They perform very useful duties, and, by their monthly reports, do much to promote the commercial interests of the towns they serve. It is reported that one of the provincial associations of these Boards of Trade (Ontario), and probably others, will be represented at the forthcoming Imperial Chambers of Commerce Congress in London, in June next, and that an effort will be made to secure the next triennial conference of the Imperial Chambers for Canada. It is intended that the Canadian representatives shall visit the chief towns of the United Kingdom for the purpose of conferring with the various chambers in matters relating to the question of promoting closer trade relations between the Mother Country and the Dominion.

Preference for British Goods.—It is interesting to note, in view of the appointment of the Imperial Commission of Inquiry referred to in a previous paragraph, that the Government of Victoria, Australia, has decided to give preference to British goods over those of foreign countries. The step taken by the Victorian Government is the first occasion on which the principle of preference to the manufactures of the United Kingdom has received general acceptance in that State. Up to the present it has been limited to the paper required by the Government printers. A few years ago, preference was allowed to British paper-makers over those of the United States and other countries, and it has proved thoroughly effective. The new provision is embodied in the conditions of tender for State supplies, which are now being circulated, and which will be operative from July 1st next, and will hold good for three years. The proviso reads, "Preference will be given to articles of British manufacture as against those of foreign manufacture." It is further stipulated that where goods are manufactured in Australia, the raw material, when not of local production, must as far as possible be of British origin. It is specifically stated that in the case of cotton goods the articles must be all British.

A Gold Discovery in Queensland.—Etheridge, Queensland, has been prospected for gold for some considerable time, and gold is reported to have been discovered in paying quantities. The Mines Department at Brisbane has received a statement from the warden that he has visited the field. He reports that he is unable at this early date to give a definite opinion as to the prospects, but, judging by appearances, he is of opinion that it is likely

Hosted by Google

to be permanent. The lode material consists of quartz and carries lead carbonate as well as gold. There is a large tract of country yet to be prospected, and it is doubtful at this point whether a rush is to be expected, as there is little, if any, alluvial in the gullies. The locality is some half-mile south of the Great Eastern copper mine, within a mile of the boundary of the Oaks Field. Some thirty claims have already been pegged out, and there are sixty or seventy men on the ground. Work has been started on three permanent outcrops, and it is reported that all are giving fair prospects.

New University for Western Australia.—Western Australia has for some time felt the want of a thoroughly-equipped modern university, and public feeling has expressed itself loudly in support of a project to establish one in the city of Perth. The preliminary arrangements have already been made and are now proceeding. A strong and representative senate has been appointed, and Mr. Hugh Gunn, who carried out a similar work successfully in South Africa, has taken up the work of organising the new institution. The Government has approved of the Perth Modern School being utilised for preliminary work in connection with the establishment. This school is ideally situated in extensive grounds, and, with adequate public and Governmental support, the undertaking should prove of considerable advantage to the State.

The Fisheries of South Africa.—The development of the Natal fishing industry has recently formed a subject of inquiry by a Commission appointed by the Union Government. The Commission was appointed some months ago to furnish the department of fisheries with scientific and commercial data, for the purpose of improving the industry. The report of the Commission recommends that "protection be given adult fish during spawning," "the scientific propagation of food fishes by artificial means," the "improvement of the methods of fishing," "commercial extension of the industry," and "the equipment of a Fisheries Department for scientific research." The Commission express the opinion that an expert should be appointed by the Government who should divide his time between Cape Colony and Natal. They state that they are satisfied that the oyster fisheries of Natal are capable of great expansion, and they strongly urge the scientific propagation of crayfish and crabs. There is abundant evidence that sponges of excellent quality are to be obtained all around the South African coast.

GENERAL NOTES.

International Association for Testing Materials.—The Sixth Congress of the International Testing Association, under the patronage of the President of the United States, will be held at New York, in the Engineering Societies' Building, from Tuesday, September 3rd, to Saturday, September 7th, 1912. The president of the Congress will be Professor H. M. Howe, of Columbia University. A large number of papers will be read and discussed, and arrangements are being made for visits and excursions to other cities in the United States. Members of the Iron and Steel Institute desirous of participating in the Congress can obtain further information on application to Mr. G. C. Lloyd, Secretary of the Institute.

Iron and Steel Institute.—The annual meeting of the Institute will be held at the Institution of Civil Engineers, Great George Street, Westminster, on May 9th and 10th, 1912. The following is the list of papers that are expected to be submitted for reading and discussion: (1) "Notes on the Solubility of Cementite in Hardenite," by Dr. J. O. Arnold and L. Aitchison, Sheffield; (2) "On the Chemical and Mechanical Relations of Iron, Vanadium, and Carbon," by Dr. [illegible]. Arnold. Sheffield, and Professor A. A. [illegible], (3) "Notes on a Bloom of R[illegible] from Corstopitum, Corbridge," by Sir [illegible]gh Bell, Bart., Middlesbrough; (4) "The Influence of Carbon on Corrosion," by C. Chappell, Sheffield; (5) "The Manufacture and Treatment of Steel for Guns," by General L. Cubillo, Valladolid, Spain; (6) "The Corrosion of Nickel, Chromium, and Nickel-Chromium Steels," by Dr. J. N. Friend, J. Lloyd Bentley, and W. West, Darlington; (7) "On the Mechanism of Corrosion," by Dr. J. N. Friend, W. West, and J. Lloyd Bentley, Darlington; (8) "Sinhalese Iron and Steel of Ancient Origin," by Sir Robert A. Hadfield, F.R.S., Sheffield; (9) "Modern Rolling-Mill Practice," by J. W. Hall, Birmingham; (10) "The Influence of Heat on Hardened Tool Steels," by E. G. Herbert, Manchester; (11) "Improvements in Electric Steel Furnaces and their Application in the Manufacture of Steel," by Dr. H. Nathusius, Friedenshütte, Upper Silesia; (12) "A New Process for the Investigation of Fractured Surfaces of Steel," by F. Rogers, Sheffield; (13) "The Welding Up of Blowholes and Cavities in Steel Ingots," by Dr. J. E. Stead, F.R.S., Middlesbrough; (14) "Note on some Remains of Early Iron Manufacture in Staffordshire," by Professor T. Turner, Birmingham.

Modern English Furniture at Olympia.—One of the most interesting portions of the Ideal Home Exhibition, now open at Olympia, is the section of modern English furniture which has been arranged by Mr. Dudley Heath. It contains numerous specimens of tables, chairs, furnishings, etc., made by the best of our modern craftsmen in wood. Many of these are excellent, both in design and execution, and are extremely interesting as showing t[illegible]t the best traditions of the art of furniture-m[illegible]king are far from dead. The Exhibition remains open until the 30th inst.

Hosted by Google

Lectures on Rubber.—A special short course of lectures on rubber (from the chemical, botanical, and commercial standpoints) will be delivered in the Chemistry Lecture Theatre of the Royal College of Science, South Kensington, by Dr. Philip Schidrowitz, Ph.D., F.C.S., consulting and analytical chemist, and Mr. Herbert Wright, A.R.C.S., F.L.S., consulting economic botanist. The lectures will be given from 5 p.m. to 6 p.m. on Mondays, Wednesdays, and Fridays, beginning on Wednesday, April 24th, 1912. Applications for admission to the course should be addressed to the secretary of the Imperial College of Science and Technology, South Kensington, S.W.

The Canadian Fishing Industry.—The territorial fishing grounds of Canada, extending from the Bay of Fundy to the Strait of Belle Isle on the Atlantic coast, and from the Fraser River to Prince Rupert on the Pacific coast, together with about one quarter of a million square miles of fresh water in C[illegible] interior, constitute not only the most [illegible] the most abundantly stocked commer[illegible] waters of the world. The total value of all k[illegible] of fish and fish products taken by Canadian fishermen during the fiscal year 1909-10, was £6,000,000. This sum constitutes a record, being the highest yet reached during any one year in the history of the Canadian fisheries. It exceeds by over £800,000 the value of fish taken in the year 1908-9. This result was obtained by 1,723 vessels, steamers and tugs, five of which were engaged in fur-seal hunting, and 41,170 boats, the whole being manned by 68,663 men. Sailing boats engaged in the shore fishery are being rapidly displaced by motor-boats.

The Cotton Industry in Japan.—In spite of the high prices of raw material, the cotton manufacturing industry of Japan is in a very flourishing condition. At the present time the number of spindles there is 2,180,000, as compared with 1,274,000 in 1900, while the quantity of cotton consumed increased from 700,000 bales in that year to 1,060,000 bales in 1911. The corresponding figures for the United Kingdom for 1911 were 54,523,000 spindles and 3,782,000 bales. It will be noticed that there is a striking difference in the consumption of cotton per spindle in the two countries; while in the United Kingdom each spindle only consumes ·07 of a bale approximately, each Japanese spindle consumes nearly ·5 of a bale. The reason of this difference is to be found in the fact that as a rule the Japanese spindles are operated day and night, and are for the most part equipped with ring spindles, which consume considerably more cotton than mule spindles. According to the Bulletin on the Supply and Distribution of Cotton recently issued by the United States Department of Commerce and Labour, Japan has at present thirty-eight factories engaged in cotton manufacture, containing 17,000 looms and employing about 93,000 men, women, and children, while it is estimated that there are still about 1,000,000 hand-looms in the country, which produce about one-third of the cotton cloth used by the inhabitants. The principal source of the cotton supply is British India, although the imports of Chinese cotton is steadily increasing. The imports from the United States of America have averaged about 200,000 bales annually. Efforts are being made to increase the supply by promoting growth in Korea and Siam.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

April 24.—George Fletcher, Assistant Secretary of the Department of Agriculture and Technical Instruction, Ireland, "Technical Education in Ireland." R. Blair, M.A., B.Sc., Education Officer of the London County Council, will preside.

May 1. — William Burton, M.A., F.C.S., "Ancient Egyptian Ceramics."

May 8.—E. D. Morel, "British Rule in Nigeria."

May 15. — Ernest Kilburn Scott, Assoc. M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere." Sir William Ramsay, K.C.B., Nobel Laureate, F.R.S., will preside.

May 22. — Gordon Craig, "Art of the Theatre." Miss Ellen Terry will preside.

Indian Section.

Thursday afternoons, at 4.30 o'clock:—

April 25.—Sir John O. Miller, K.C.S.I., "The Central Provinces." The Rt. Hon. Lord MacDonnell, G.C.S.I., K.C.V.O., will preside.

May 16.—Neville Priestley, Managing Director, South Indian Railway, "Indian Railways."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

May 7.—Alan Burgoyne, M.P., "Colonial Vine Culture."

May 21.—The Hon. J. G. Jenkins, "Australian Railways."

Howard Lectures.

Monday evenings, at 8 o'clock:—

Captain H. Riall Sankey, R.E. (retired), M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

Syllabus.

Lecture I.—April 29.—The oil engine is an internal combustion engine—Difference between light and heavy oil engines—Difference between Diesel and other heavy oil engines—Brief history of the Diesel engine—Theoretical thermal efficiency—Heat and other losses—Actual thermal efficiency

Hosted by Google

—Efficiency ratio—Thermal efficiency compared with other internal combustion engines and with external combustion engines—Cycle of operation of a 4-stroke and of a 2-stroke Diesel engine, and essential parts to produce these cycles.

LECTURE II.—MAY 6.—Various types of Diesel engines—Considerations affecting design—Design of various parts, such as cylinders, valves, pistons, connecting rods, crank shafts, frames, air compressors, etc., for 4-cycle and for 2-cycle engines—Materials used for the various parts—Number and arrangement of cylinders for vertical and horizontal engines.

LECTURE III.—MAY 13.—Description of Diesel engines manufactured by various makers—Sizes in current manufacture and future possibilities—Speeds and weight for land and marine engines—Various kinds of oil available for Diesel engines; their characteristics, calorific value, and sources of supply.

LECTURE IV.—MAY 20.—Economical results in respect of fuel and of total annual cost—Comparison of Diesel, gas and steam engines, in respect of capital cost, fuel cost, and total annual cost—Various applications to land and marine purposes—Other heavy oil engines—Semi-Diesel engines.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 22...Post Office Electrical Engineers, Institution of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 5 p.m. Annual General Meeting.

Geographical, Burlington-gardens, W., 8.30 p.m. Mr. A. E. Kitson, "Southern Nigeria."

British Architects, 9, Conduit-street, W., 8 p.m. Mr. C. H. Townsend, "The Royal Institute Library and Some of its Contents."

TUESDAY, APRIL 23...Statistical, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Mr. G. Udny Yule, "On the Methods of Measuring Association between Two Attributes."

Faraday Society, at the Institute of Electrical Engineers, Victoria-embankment, W.C., 8 p.m. 1. Dr. E. Gumlich, "On the Magnetic Properties of Iron-Carbon and Iron-Silicon Alloys." 2. Professor E. Wedekind, "The Dependence of Magnetisation on Composition in Chemical Compounds." 3. Doctors A. D. Ross and J. G. Gray, "The Magnetic Properties of a Variety of Special Steels at Low Temperatures," and "The Heusler Alloys." 4. Doctors S. Hilpert and E. Colver-Glauert, "The Magnetic Properties of Nickel and Manganese Steels with reference to their Metallographical Composition," and "The Magnetic Properties of the Compounds of Manganese with Phosphorus, Arsenic, Antimony, and Bismuth." 5. "The Nature of the Heusler Alloys":—Dr. E. Take, "The Physical Aspect"; 6. Dr. F. Heusler, "The Chemical Aspect." 7. Professor A. A. Knowlton, "Variation of Ferromagnetic Properties of the Heusler Alloys with Composition and Heat Treatment." 8. Professor C. F. Burgess and Mr. James Aston, "The Relations between the Mechanical Hardness and the Retentivity and Permeability of Ferro-Alloys." 9. Professor Pierre Weiss, "The Magnetic Properties of the Iron-Nickel, Iron-Cobalt, and Nickel-Cobalt Alloys." 10. General Discussion on "Magnetic Properties of Alloys."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. E. Gosse, "Algernon Charles Swinburne: his Early Life and Work." (Lecture II.)

Quekett Microscopical Club, 20, Hanover-square, W. 8 p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on papers by the Hon. Sir Francis J. E. Spring, "The Remodelling and Equipment of Madras Harbour," and Mr. H. H. G. Mitchell, "The Alteration in the Form of Madras Harbour."

Photographic, 35, Russell-square, W.C., 8 p.m. Messrs. C. E. Kenneth Mees and C. Welborne Piper, "On the Fogging Power of Developers. Part II.—Determinations of the Solubility of Silver Bromide in Sodium Sulphite and other Solvents."

Zoological, Regent's Park, N.W., 8.30 p.m. 1. Mr. Julian S. Huxley, "A First Account of the Courtship of the Redshank (*Totanus calidris*)." 2. Mrs. E. W. Sexton, "Amphipoda from Bremerhaven." 3. Mr. C. Tate Regan, "Descriptions of new Fishes of the Family Loricariidæ in the British Museum Collection." 4. Mr. Charles H. O'Donoghue, "The Circulatory System of the Common Grass Snake (*Tropidonotus natrix*)."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mr. A. E. Shipley, "Universities and Practical Education."

WEDNESDAY, APRIL 24...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. George Fletcher, "Technical Education in Ireland."

East India Association, Caxton Hall, Westminster, S.W., 4.30 p.m. Sir William Chichele Plowden, "Problems of Indian Administration."

Royal Society of Literature, 20, Hanover-square, W., 5 p.m. Mr. J. Offord, "New Discoveries of Classical Literature."

United Service Institution, Whitehall, S.W., 3 p.m. Brigadier-General H. De B. De Lisle, "The Strategical Action of Cavalry."

THURSDAY, APRIL 25...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Sir John O. Miller, "The Central Provinces."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 8 p.m. Discussion on two Reports presented by the Tests Standing Committee:—1. "The Testing of Concrete, Reinforced Concrete, and Materials Employed therein." 2. "The Testing of Reinforced Concrete Structures on Completion."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. W. Crossley, "Synthetic Ammonia and Nitric Acid from the Atmosphere." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. C. E. Dawson, "Costume."

Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Third Kelvin Lecture by Professor H. du Bois (Berlin).

FRIDAY, APRIL 26...Royal Institution, Albemarle-street, W., 9 p.m. Sir George H. Darwin, "Sir William Herschel."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. (Students' Meeting.) Mr. T. F. Thomson, "The Principles and Practice of Accountancy in Relation to Engineering Design and Work."

Engineers and Shipbuilders, North-East Coast Institution of, Newcastle-on-Tyne, 7.30 p.m.

Physical, Imperial College of Science, South Kensington, S.W., 5 p.m. 1. Discussion of Mr. H. Donaldson's paper, "The Coefficients of Expansion of Fused Silica and Mercury." 2. Mr. R. Appleyard, "The Solution of Net-work Problems by Determinants." 3. Mr. S. Butterworth, "A Method of Measuring Small Inductances."

SATURDAY, APRIL 27...Engineers and Shipbuilders, North-East Coast Institution of, Newcastle-on-Tyne, 7.15 p.m. (Graduates' Section.) Mr. A. T. Thorne, "Oil Engines."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. R. Blomfield, "The Architecture of the Renaissance in France. Lecture II.—1547-1594. Architecture and the Court."

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,101. VOL. LX.

FRIDAY, APRIL 26, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, APRIL 29th, 8 p.m. (Howard Lecture.) CAPTAIN H. RIALL SANKEY, R.E. (retired), M.Inst.C.E., "Heavy Oil Engines." (Lecture I.)

WEDNESDAY, MAY 1st, 8 p.m. (Ordinary Meeting.) WILLIAM BURTON, M.A., F.C.S., "Ancient Egyptian Ceramics." CHARLES HERCULES READ, LL.D., President of the Society of Antiquaries, Keeper of the Department of British and Mediæval Antiquities and Ethnography, British Museum, will preside.

Further details of the Society's meetings will be found at the end of this number.

INDIAN SECTION.

Thursday afternoon, April 25th; THE RIGHT HON. LORD MACDONNELL, G.C.S.I., K.C.V.O., in the chair. A paper on "The Central Provinces" was read by SIR JOHN O. MILLER, K.C.S.I.

The paper and discussion will be published in a subsequent number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

EIGHTEENTH ORDINARY MEETING.

Wednesday, April 24th, 1912; R. BLAIR, M.A., B.Sc., Education Officer of the London County Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Halford, George, A.R.C.A., 11, Foden-road, Walsall.

Japp, Henry, 507, Fifth-avenue, New York City, U.S.A.

The following candidates were balloted for and duly elected members of the Society:—

Brandon, James Augustine, Battery House, Nepean Sea Road, Bombay, India.

Davidson, Alexander Rae, 150, Stradbrooke-place, Winnipeg, Canada.

Goodenough, Francis William, 1, Young-street, Kensington-square, W.

Groundwater, William, The Rising Sun Petroleum Company, Yokohama, Japan.

Maclachlan, Thomas, Mount Lavinia, near Colombo, Ceylon.

Payne, Harold William, Box 210, Durban, Natal, South Africa.

THE CHAIRMAN, in introducing the lecturer, said he was glad to be in the chair, because Mr. Fletcher and he were colleagues in the Science and Art Department for a good many years, and afterwards in much closer relationship as colleagues in Ireland for four years. Mr. Fletcher had been assistant Secretary of the Department of Agriculture and Technical Instruction since 1904, which meant that he was head of the branch which dealt with technical instruction in Ireland; and he (the Chairman) expected from what he knew of Mr. Fletcher, and what he knew of the subject, that the audience would hear a very interesting paper.

The paper read was—

TECHNICAL EDUCATION IN IRELAND.

By GEORGE FLETCHER, F.G.S.,

Assistant Secretary of the Department of Agriculture and Technical Instruction for Ireland.

In 1900 a great and far-reaching educational experiment was initiated in Ireland. I call it an experiment, for most people, not without some reason, regarded the work which was to develop into a system of the profoundest importance as an experiment, and as an experiment of which the success was doubtful. This movement was made possible by the passing of the Agriculture and Technical Instruction (Ireland) Act, which was placed on the Statutes in 1899, and which

Hosted by Google

itself grew out of the work of a Committee worthy of remembrance. This Committee, of which Mr. (now the Right Hon. Sir) Horace Plunkett was chairman, and Mr. T. P. Gill honorary secretary, was known as the Recess Committee. It consisted of Irish Members of Parliament and other Irishmen of different shades of political opinion. After making extensive inquiries at home and abroad, they issued a report, which they presented to the Irish Government, recommending the establishment of a Department of Government to administer State aid to agriculture and industries in Ireland, together with the technical instruction relating thereto. A Bill was introduced by Mr. Gerald Balfour, then Chief Secretary for Ireland, and was passed into law in the same year.

The task which lay before the new Department may fairly be described as colossal. Technical education did not exist except in the large cities, while that scientific education upon which technical education can alone be based was almost non-existent in primary and secondary schools. Shortly before the creation of the new Department, the National Education Board, which is the body mainly responsible for primary education, had, as a result of the recommendations of the Commission on Manual and Practical Instruction (1898), introduced the teaching of science and hand and eye training into Irish National schools, but in Irish secondary schools the teaching of science was almost extinct. A few hundred candidates presented themselves for the Intermediate Board's Examinations in "natural philosophy," and certain specific subjects of science, but it is enough to say that these examinations were wholly written, and that laboratories did not exist in the schools. Here and there were brilliant instances of good work performed under great difficulties, but the facts I have mentioned would of themselves account for the absence of a system of technical education. There existed, it is true, science and art classes, which, scattered over the country, worked in connection with the Department of Science and Art, South Kensington, and were supported by the grants earned under its regulations; but these declined, as they were bound to do, until the amount coming to Ireland from the Science and Art grant fell to £2,819 in the session 1900–01. Those who are familiar with the history of English education will remember the great stimulus afforded by the passing of the Local Taxation Act of 1890, under which large funds were made available for technical instruction in England. Ireland's share of the local taxation duties paid to the local taxation account was not devoted to technical education in Ireland. A portion of it—£78,000—went to the Commissioners of National Education, though it was transferred to the Department under the Act of 1899. The residue was allocated to the Intermediate Board, and was devoted to general secondary education. It is not easy to say what else could have been done at the time. There was no local or central authority capable of dealing with the problem of technical education. County councils were not established in Ireland before 1898 (eight years later), and though there was power to raise a penny rate for technical education, the amount actually raised was ridiculously small—something like one-twentieth of that raised to-day. Thus for ten long years, from 1890 to 1900, while England was rapidly developing a system of technical education under the stimulus of the "beer and spirit" money, Ireland was steadily going backward.

There are, however, some points of light in this gloomy picture. Ireland has always been a lover of education. Her world-famed monastic and bardic schools, which flourished from the fourth to the tenth centuries—until their destruction, in fact—and her brilliant scholars and theologians justly earned her the title, "Insula Sanctorum et Doctorum." This love of learning, though quenched, has not been extinguished in the course of succeeding centuries, and is readily awakened by a sympathetic touch. Another advantage characterised the situation—a fairly clean slate, if not a *tabula rasa.* There were relatively few vested interests, such as beset the path of educational reformers in other countries, fewer prejudices, and a fair, if cautious, attitude towards novel proposals. To change the metaphor, the technical educator, though beset by many difficulties, had before him an untilled field and a soil which, as events have shown, was by no means unfertile. We were, moreover, able to profit by the experience gained in other countries, and thus taught to avoid the dangers and pitfalls they had encountered.

It will be necessary to say a few words as to the powers and duties conferred on the new Department by the Act.

In addition to the sum of £55,000 per annum allocated to technical education other than agricultural, power is conferred upon local authorities to raise a rate of one penny in the pound for the purposes mentioned in the Act. They already possessed the power of raising a penny rate under the Technical Instruction Act of 1889.

Hosted by Google

Provision was also made, and this is an important point, for the transfer to the Department of the administration of the grant for science and art in Ireland, and of such powers and duties as the Department of Science and Art, South Kensington, had previously exercised in regard to the Royal College of Science, the Metropolitan School of Art, and other central institutions. The Department were empowered to give aid to agriculture and to home industries, but for other forms of industry aid was limited to educational training. There was provision for the creation of committees by the councils of counties, county boroughs, and urban districts, and also for the formation of joint committees of two or more of these bodies. These committees consist of members of the respective councils with co-opted members. Two central boards of an advisory character were to be formed, one for agriculture and the other for technical instruction, and also a larger body—the Council of Agriculture. These bodies consist of elected members, together with a certain number nominated by the Department. The Council of Agriculture is purely advisory, but the Boards control the expenditure of the Department's endowment fund.

The Board of Technical Instruction consists of twenty-one members, of whom fifteen are appointed by local authorities, one each nominated by the Commissioners of National Education and the Intermediate Education Board, while four are nominated by the Department. The Board controls the expenditure of the endowment of £55,000 for technical education, the distribution of which is subject to triennial revision. It is provided in the Act that this sum shall be divided into two portions, one of which shall be divided between the county boroughs (of which there are six), in proportion to their respective populations, the other portion being available for the rest of the country. It will not be necessary that I should explain the mode of distribution, which is partly based on population. The funds thus allocated may only be expended by the local authorities under the conditions of a scheme approved by the Department with the concurrence of the Board of Technical Instruction, and one invariable condition is the contribution of local aid to the scheme. A rate of a penny in the pound is the local contribution for all urban centres, and is the amount ordinarily devoted to the technical and agricultural schemes in the counties. Some few of the urban centres contribute more, and a few of the counties slightly less than this amount. The Department consists of a president, who is the Chief Secretary for Ireland, of a vice-president, a secretary, and two assistant secretaries (one for agriculture and one for technical instruction), with a staff paid out of a Parliamentary Vote. The first Vice-President was Sir Horace Plunkett, whose work in the cause of agricultural organisation in Ireland is well known to you. The Vice-President, under the existing administration, is the Right Hon. T. W. Russell, who represents an Irish constituency in Parliament; while the secretary is Mr. T. P. Gill, who has occupied this office since the Department was established, and was honorary secretary of the Recess Committee, to which I have referred as having cleared the way for the Act which created the Department.

Having thus briefly outlined the constitution of the Department, it will be useful to indicate one or two leading principles according to which the Department have shaped their educational administration. They were desirous from the first to develop a system of technical education in harmony with the peculiar needs of Ireland in a manner best calculated to further its industrial progress. Progress was necessarily slow for the first year or two, but the foundations were being well laid. It was realised, perhaps more clearly than in this country, that a sound system of technical education can only be erected on the broad and strong foundation of a good general education—an education which shall include the fundamental principles of science, taught practically, the aim of which is not to enable the student to pass a uniform theoretical examination, but to foster the spirit of inquiry and enable him, by means of a well-designed course of practical work, to educate his executive powers, and to give him a real insight into scientific method. The Department therefore seized upon an opportunity for reforming the teaching of science in Irish secondary schools. The great majority of these schools work under the programme of the Intermediate Education Board of Ireland, which distributes its funds in aid of secondary education on the basis of written examinations held annually. When the Department began its work the teaching of science in these schools had declined almost to vanishing point, and even that taught under the head of "natural philosophy," etc., was almost entirely theoretical in character. There were not more than five or six science laboratories in the whole of the secondary schools of Ireland. Such schools were, however, eligible for grants from the Vote for science and art teaching, the administration of which had been transferred

Hosted by Google

from South Kensington to the Department. This Irish body, therefore, immediately formulated a programme providing for the encouragement of the teaching of experimental science, drawing and manual work, with domestic economy in the case of girls' schools. The programme provides for a four years' course in these subjects, the first two years being a preliminary course, compulsory on all schools adopting the programme, and this is followed by a two years' special course, the subjects of which are now physics, chemistry, mechanics, botany, physiology and hygiene, physical and commercial geography, domestic economy, and drawing. Any one of these may be taken and not more than three. The conditions laid down were irksome, but necessary. No school can be recognised unless it has a properly equipped laboratory, or which has not a properly qualified teacher—one who has received a training in laboratory work. Where these conditions are satisfied grants become payable on a basis which may be described as a capitation attendance-hour efficiency method. The grant, that is to say, depends upon the amount of work done and upon its excellence as determined by inspection. Examinations find no place in the Department's schemes as a means of assessing aid for educational purposes from public funds, and thus examinations are coming to occupy their due place—so far as the Department's operations are concerned—as a means of testing progress, and as providing a real test of individual ability, untrammelled by considerations of "grant." Under the Department's schemes the normal grant, as determined by the number of students and the amount of time devoted to their instruction, may be increased by one-tenth or reduced by one or more tenths on the report of the Department's inspectors. I am well aware of the risks attendant upon the delegation of wide powers to inspectors, but I may say, as a result of long experience in all types of school in England and in Ireland, that where inspectors are carefully chosen these risks become insignificant as compared with the evil consequences of assessing grants on the results of examinations. Happily this evil has ceased to exist in England.

I have spoken of the severe conditions imposed by the Department on schools desiring to work under its programme. These conditions might, indeed, have proved fatal but for two circumstances. Firstly, the enthusiasm and adaptability displayed by Irish secondary schools and schoolmasters, who welcomed the new programme notwithstanding its difficulties; and, secondly, the steps taken by the Department to solve these difficulties. The Department could give no aid for building laboratories, but they gave generous aid towards the provision of fittings and other equipment. Nearly fifty thousand pounds were thus expended, the schools providing the required accommodation. But perhaps the greatest difficulty was that of securing teachers qualified to conduct courses of instruction which involved practical work carried out almost entirely by the students themselves. This difficulty was enhanced by the fact that over the larger portion of Ireland secondary education is carried out by religious orders, the members of which, in the case of convents, are not free to attend public courses of instruction. The difficulty was met by the establishment of summer courses of instruction for teachers held in Dublin, Belfast, Cork, and other centres. In the case of convents, nuns were grouped in selected convents, which provided adequate laboratory accommodation, and specially qualified teachers sent to conduct the prescribed courses. Each course lasts nearly a month, and teachers not otherwise qualified are required to attend at least five such courses, and pass the theoretical and practical examinations at the close of them before receiving full recognition. These summer courses have now been held for the last nine years, and between 600 and 700 teachers receive instruction each year. It was the intention that these courses should only serve a temporary need, and that under normal conditions the training of teachers should be accomplished by the universities, by the Royal College of Science, the Metropolitan School of Art, and other institutions administered by the Department. We have not, however, found it desirable to discontinue these courses as yet. They have been found to serve a most valuable purpose, not only in relation to teachers in secondary schools, but also for teachers in technical schools and others engaged in various branches of the Department's work.

The results have been most gratifying. The movement was, as I have said, taken up with enthusiasm, but could never have become so general had it not been for a valuable piece of co-ordination with the Intermediate Board. Under the Act of 1899 there was established a consultative committee, consisting of representatives of the Department, the National Board and the Intermediate Board, having for its object the co-ordination of educational administration. Acting on the recommendations of the Committee, the Intermediate Board adopted the

Hosted by Google

Department's programme to replace their own syllabus of "natural philosophy," and also accepted the Department's inspection in lieu of their own pass examination in the subjects in question. The result has been that the teaching of experimental science has been placed on a firm basis in Irish secondary schools. In the first year in which the programme was introduced 154 schools adopted it, while in the present session there are 278 schools, in 240 of which special courses are in operation, with 14,516 individual students taking science. Domestic economy is taught in sixty-two of these schools, and manual instruction in sixty-six. The total amount of grant earned in 1900–01 was £2,366, which rose to £27,955 for the session 1911–12. The work done in the schools will bear favourable comparison with that done elsewhere, and provides an excellent preparation for teaching of a technological character. I should add that drawing is compulsory in the preliminary course on all students taking science, and that in the case of schools unable to retain students for the special courses manual instruction is compulsory. This condition assists in some small degree in securing a much needed grading of schools.

The attitude of teachers towards the programme, and the excellent relations between them and the Department must be attributed in some measure to the existence of a committee of headmasters, representing various types of secondary schools, and appointed by the Department with the object of securing occasional conferences with the Department for the purpose of discussing difficulties, suggestions, and proposed alterations in the programme.

The work to which I have referred at such length, while fundamental and indispensable, is, however, not the work for which the Department was primarily called into existence. It was nevertheless a condition precedent to the operations I am about to describe. The secondary schools are administered directly by the Department, while the funds for technical education are almost wholly administered through the committees of local authorities. These bodies were invited to formulate schemes of technical instruction, and to submit them for the approval of the Department. In doing so they were aided by the Department's inspectors, who constantly confer with committees and assist them in framing and revising their schemes.

The schemes for the different counties vary considerably, but they generally contain some features in common, the Department having drawn up on a common basis schemes suited to rural needs all over the country, which are adopted by local authorities and become constituent parts of their schemes. In elaborating these the Department recognised that in rural districts little more could be done than to supplement the teaching given in various branches of agriculture, but that little was of vast importance and sought (1) to carry into the remote parts of rural Ireland such forms of technical instruction as are best suited to their needs—especially such instruction as will bear upon home-life and tend to make the countryside more bright and prosperous; (2) to give facilities for the boy of exceptional ability to continue his studies in a centre where suitable schools exist, and to direct his efforts into an industrial channel.

We have sought to realise the first of these aims by organising a system of instruction in small centres by utilising the services of itinerant teachers of domestic economy, manual instruction in wood, home industries, etc. Specially-trained teachers with portable equipment remain in a centre for a period varying from six weeks to six months, according to circumstances; the locality, where possible, provides accommodation, the equipment being provided by the Technical Instruction Committee. Classes are held daily in the afternoons and evenings, and some excellent work has been done. In the manual work classes technical drawing is taught, and the making of useful articles, such as beehives, wheelbarrows, and the like has not been found incompatible with the teaching of principles. These classes have been freely attended by young farmers and tradesmen. The courses in domestic economy include cookery, laundry-work, home-sewing, and home-nursing, and hygiene. Hundreds of these courses are held every year. There are now some 110 domestic economy teachers and eighty-five manual instructors at work in small towns and rural centres. The scheme, no doubt, possesses certain inherent defects, but I have never heard of a better one for extending the advantages of an education of this character to sparsely-populated rural areas.

A more thorough training in the duties of home life is afforded by a number of residential schools for girls, in which a carefully-planned course of instruction extends over one year. Scholarships of the value of £15 are given by a number of county committees to enable girls to take these courses. The Department directly administer one school for the training of domestic servants—the Killarney School of

Hosted by Google

Housewifery. The Department have, moreover, aided in the establishment of three higher residential schools of domestic economy, in connection with secondary schools in Waterford, Londonderry, and Sligo, for girls who have received a good secondary education. These follow a year's course in household management.

The second of the aims referred to we seek to attain by means of scholarships. These are awarded by county technical committees aided by special grants from the Department. They are awarded by means of a competitive examination, conducted by the Department, to boys attending primary schools. Until recently, these scholarships were tenable at ordinary secondary schools, but it was found that they failed in their intention of providing a training such as would fit a boy for an industrial career. The scheme has, therefore, been revised in an important manner. The scholarships now carry a boy from the primary school to a day trades preparatory school (of which twelve have been established under a special scheme by the Department), at which he will remain for two years, and on his being apprenticed to a trade under such conditions as the Department approve, he retains the scholarship, which guarantees him a maintenance allowance of 15*s.* per week until he becomes a journeyman. An essential condition is, of course, that during the whole period of apprenticeship he shall attend an approved course of instruction in an evening technical school.

In addition to the scholarships just mentioned, there are several other types, such as the local science and art scholarships, local exhibitions, and the more valuable scholarships tenable at the Royal College of Science and the Metropolitan School of Art. There have also been a limited number of industrial scholarships affording their holders, who must be actually engaged in a trade, a course of training in the technological department of a university or other place of higher technical training.

The Department could not fail to be solicitous respecting the numerous home industries which have in rural Ireland proved so useful in supplementing the slender earnings of the peasantry. Ireland is world-famed for its laces, crochet and embroidery, and no less so for the sterling merits of its homespuns, its hosiery and many other products. In these the Department have assisted by means of grants for the salaries of teachers of drawing and design, by expert advice, and in other ways. The many imitations of these excellent products of Irish skill and industry have been flattering but not all sincere, and friends of Ireland, who desire to assist Irish industry and enrich themselves with these artistic products, will be wise in satisfying themselves beyond possibility of doubt when they ask for Irish products that they really get them. Large quantities of lace and crochet closely imitating Irish *motifs* and *technique* come from places far east of the longitude of Greenwich.

In addition to the industries which may be styled indigenous, new industries suited to the conditions of the country are being introduced. Among these may be mentioned the furniture-making industry of the "Kilkenny Wood-workers," with which the name of the late Captain Otway Cuffe will always be gratefully remembered, the glove-making industry of Tipperary, and the more recent establishment of a school of machine embroidery at Bally-dougan, near Gilford in County Down—an effort which has already given proof of success, to do in Ireland for Irish linen goods what has hitherto been done in Switzerland. Among the art crafts reference should be made to the beautiful stained glass produced by Miss Purser in Dublin, and the stained glass and exquisite enamels produced by the workers and students of the Metropolitan School of Art. It seems superfluous to add that such developments are necessarily of slow growth. It was not unnatural, though it was unreasonable, that no sooner had technical education been established in Ireland than people should ask to see proofs of its effects in increased industrial prosperity. Ireland's industries have suffered grievous wrongs in the past, and the effects of those injuries cannot be repaired in a hurry. But there are abundant signs of a rapidly-growing spirit of constructiveness, and the success of the technical schools, the creation of various industrial development associations, the local industrial shows and *Feiseanna*, all bear evidence of this fact.

As I have already pointed out, instruction in agriculture must be regarded as of paramount importance in rural districts. As in the case of technical education of a non-agricultural character, it was found that the needs of rural areas could best be met by an itinerant system. The first efforts of the Department were in the direction of pioneer lectures. These gave place to courses of lectures, and instructors are employed by county committees under the schemes for the teaching of agriculture, horticulture and bee-keeping, poultry-keeping and butter-making. There are about 130 trained

Hosted by Google

instructors thus employed. The instructors deliver evening lectures or conduct day classes; they visit farms, gardens, poultry runs and dairies for the purpose of giving advice individually, and also conduct field or garden demonstrations. The effect of this itinerant work has been to create a demand for courses of instruction of a more thorough character than can be provided by evening lectures, and the Department is rapidly developing its scheme of winter agricultural classes. These classes are held for two or three days weekly during the period of about sixteen weeks from November to March, and in the session 1910–11 twenty-seven counties were working this scheme, there being seventy-eight classes attended by 1,339 students. For a more complete training for those who can go into residence, there are agricultural schools at Athenry, Ballyhaise, and Clonakilty; while for girls there are eleven agricultural schools, of which nine are residential. The Munster Institute at Cork, and the Ulster Dairy School at Cookstown, County Tyrone, are central institutions managed by the Department directly. The other nine are schools of rural domestic economy, and are working under private management, subject to the Department's supervision. While a number of pupils are residential, the schools are intended chiefly for girls living in the immediate neighbourhood. The principal subjects of the programme are, dairying, poultry-keeping, cottage gardening, and other branches of domestic economy.

Hitherto I have dwelt almost exclusively with our educational operations in rural areas. The growth of technical education in the towns of Ireland has been no less remarkable. No sooner were opportunities afforded for the youth of Ireland to get technical education than they crowded into the temporary buildings called schools in such numbers as to cause embarrassment. Such a result was wholly unexpected—still more unexpected the pertinacity with which they remained, and returned in succeeding sessions. All sorts of buildings were pressed into the service—private houses, disused chapels; in one place you may still find a technical school underneath a large water-tank which supplies the town with water. In another an adapted fever hospital; in another a disused gaol; indeed, disused gaols, ill-adapted for collective teaching, are a drug in the educational market. It was doubtless wise to commence in this manner, for, strange as such a statement may appear, it was necessary to show that the movement was permanent. In any case, we had to make a virtue of necessity, for the Act of Parliament which provided an annual endowment for promoting a system of technical education, made no provision for building technical schools. But, after the lapse of a few years, an altogether irresistible demand was made for more adequate buildings, and the Department was bound to approve plans and the raising of money for the erection of schools, borrowed on the security of the rate, the repayment of the principal and interest forming a first charge on the annual income of the committee. This, of course, constitutes a very serious item of expenditure, especially at a period when increased accommodation demands an expansion of the educational scheme. During the last few years, then, we have seen the erection of excellent school buildings in Dublin, Belfast, Cork, Londonderry, Waterford, and a number of smaller towns. The financial position would have been a hopeless one, but for the fact that we obtained in 1906 the sanction of the Treasury to a revised scheme for the administration of the science and art grant. This, while it produced a large increase in the income of the technical schools, enormously increased their efficiency, for the regulations under which grants might be earned demanded capable organisation and high efficiency.

The salient features of these regulations are of general interest, and may be summarised as follows:—

(1) The provision of courses of instruction based on a study of local industrial conditions designed to extend over a period of three or four years.

(2) An entrance qualification for those seeking admission to the courses of instruction.

(3) A preparatory course for those who have only a *minimum* qualification.

(4) Specialised courses for four years in commercial subjects, pure and applied science, handicraft, domestic science, and art, carrying a graduated scale of grants for successive years, depending upon the number of students and hours of attendance, and subject to an increase of one-tenth or a decrease of one or more tenths, as the Department, in consideration of their inspectors' reports, may determine.

(5) An increment grant for continued attendance up to a limit of 120 hours.

(6) Special provision for teachers' classes.

(7) A special scheme for apprentice classes, and for schools of art under which the

Hosted by Google

Department pay three-fourths of expenditure which has been approved by them.

(8) Provision has been made during the current session for the payment of grants on a lower scale for the teaching of single subjects suited to the needs of centres too small to organise *courses* of instruction.

To this I may add that the fullest provision is made for securing that teachers should be well-qualified, and that the equipment should be adequate. The efficiency of the instruction is ascertained by inspection, and examinations find no place among the criteria for assessing the grant. At the same time, it may be pointed out that Irish technical schools have freely availed themselves of the examinations of the Board of Education (which have up to the present been conducted by the Department), of this Society, and of the City and Guilds of London Institute. The changes made in the science examinations of the Board of Education have made them unsuitable for our needs, and we are now organising a scheme of examinations suited to our own system of education.

The scheme thus briefly outlined has, on the whole, worked excellently. It allows of great flexibility, and encourages schools to adapt their curricula to local requirements. There is, in consequence, a refreshing diversity among Irish technical schools.

The question of the course system is, as in England, one in regard to which there is some difference of opinion, but of this I am sure: the scheme as it exists has been the means of bringing into clear view the aim for which both school and student is—or ought to be—striving. It has checked that aimless discursiveness and *dilettantism* which were so common when the educational *menu* placed before a student consisted of twenty-six scientific dishes (or as many of them as the school could offer), from which he selected such items as seemed most likely to suit his appetite rather than his needs. Many of us have observed the lamentable consequences of such a meal, in which digestion was confounded and assimilation impossible. The scheme I have outlined throws upon the school and the teacher the duty of ascertaining what are the real needs of the student, and of devising a course of instruction to satisfy those needs. The field of education with which we are concerned demands "intensive" cultivation, and a well-arranged curriculum must make provision of courses for its students.

The technical schools, among their other functions, are performing a useful service in the further training of teachers of primary schools. In conjunction with the Board of National Education, the Department encourage the formation of classes of teachers in their schools. This work, begun in a tentative manner in 1903–4, has greatly increased, and large numbers of teachers now attend special classes in experimental science, drawing and domestic economy. We have further framed a scheme for the training of national teachers in rural science and school gardening. The National Board undertake the payment of travelling expenses of teachers qualified to attend these courses. Where conditions make it possible, technical schools conduct centre classes in domestic economy for pupils of National schools. It will thus be seen that educational co-ordination is not unknown on the part of the bodies responsible for education in Ireland.

Reference has already been made to the trades preparatory schools, of which there are now twelve, ten being conducted by local authorities and two by the Christian Brothers in Belfast and Cork. These schools go some way towards meeting the great need for a type of school in which boys who are to follow a trade will receive, on attaining the age of thirteen or fourteen, a preparatory education designed to fit them for entering on such a career. The subjects of the curriculum are experimental science, drawing, mathematics, manual instruction, practical geometry, and literary subjects, including one modern language as well as English.

The schools are attended in the present session by about 560 pupils. It is noteworthy that boys attending these schools are in general readily "placed" on leaving. Indeed, a difficulty is experienced in retaining pupils for the full course extending over three years on account of the demand by employers for boys attending these schools.

In carrying out such a system of technical education as I have briefly described, perhaps the most important factor is that of the teacher. No educational scheme, however well devised, can work well if it neglects to make provision for the supply of duly qualified teachers, and the Department have regarded this question as one of paramount importance. Thus, in organising a scheme of manual instruction for rural and urban areas, the Department selected by means of competitive examination young tradesmen of ability, for whom they arranged special courses of instruction extending in one case over six, and in another over eight months,

Hosted by Google

giving a maintenance allowance during the period of training. They have also held special summer courses in various cognate subjects annually for the further training of the teachers thus prepared. They have by this and other means created a corps of excellent teachers of manual work. Teachers of domestic economy are trained by means of a course extending over three years at the Irish Training School of Domestic Economy — a residential school administered directly by the Department. Teachers of science and of agriculture are trained in a course extending over three years at the Royal College of Science for Ireland, an institution whose operations can now, happily, be extended, thanks to the provision of the magnificent building which was opened by his Majesty the King in July of last year. This College provides scientific and technological instruction of university standard, and embraces faculties in agriculture, applied chemistry and engineering. Agricultural students receive a portion of their training at another of our central institutions, the Albert Agricultural College, Glasnevin, while female students and teacher students of dairy work, poultry rearing, etc., are trained at the Munster Institute at Cork.

Art teachers are trained in the Metropolitan School of Art, a Departmental school which performs for Ireland the same functions that the Royal College of Art does for England.

Teachers of lace and crochet are trained in the Cork School of Art, at which summer courses are also arranged for such teachers, while a school has been established, exclusively for the purpose of training teachers, under the Fermanagh county scheme at Enniskillen.

Teachers of commerce have been trained by means of scholarships tenable for two years, and these have been held at the London School of Economics. As a result, higher commercial training has developed in a remarkable manner during the last few years, and successful schools have been established in Rathmines, Cork, Limerick, and elsewhere. In Belfast commerce is dealt with as a section of the Municipal Technical Institute, the splendid organisation of which entitles it to rank with the finest of such institutions in the Kingdom.

DISCUSSION.

The Chairman, in opening the discussion, said it was very interesting to a London audience to carry its mind from technical education in London to technical education in rural Ireland, but it appeared that it was much the same work actually being carried on in both places. The slides had shown technical education in the rural districts of Ireland as well as technical education in Belfast. There had been represented the two phases of technical education as known in these islands. In Belfast the task was practically the same as in the great cities of England and Scotland, that was, to apply education to existing industries, whereas in the rest of Ireland the task was just the opposite, that of providing education out of which industries would develop. The second task was an infinitely more difficult one than the first. It required not only the making of an industrial population, but capital to make an industrial nation. That was the task before the Department of Agriculture and Technical Instruction when it started work in 1900. The Department consisted in the main of two branches—Agriculture and Technical Instruction. The author had sketched in the paper the work of the branch of agriculture, and he (the Chairman) thought that those who knew that branch, and the work of the Department in that respect, would probably be of the opinion that, on the whole, there was nothing in the three kingdoms like it. The author had also dealt in great detail with the work of technical instruction, that was to say, the providing of the industrial population. The Department had also a third side, the Department of Fisheries, and one or two additional pieces of work which were handed over to it by various predecessors. There were one or two points in the paper which were particularly interesting to an English audience, the first, the great difficulty with the Department of making teachers, and some importation of teachers had to be effected from England and Scotland in order to make the teachers in Ireland who had succeeded them. He thought all the English and Scotch teachers who were brought over were always able to say they had very apt material in the Irish student. Another interesting paragraph in the paper was as follows: "In the first year in which the programme was introduced, 154 schools adopted it" (experimental science), "while in the present session there are 278 schools, in 240 of which special courses are in operation." The author did not remark that a great many of those schools were private schools—private as the term was understood in England. Those private schools, in order to take advantage of the Department's grant and to place themselves at the public service in Ireland, opened themselves to public inspection. Another interesting point was with regard to scholarships to boys for learning trades: "The boy retains the scholarship, which guarantees him a maintenance allowance of 15*s.* per week until he becomes a journeyman." The author further said: "Among the art crafts, reference should be made to the beautiful stained glass produced by Miss Purser in Dublin." That was very interesting, but it required an added touch to a London audience, that a teacher—Mr. Child—was imported from the Central School of Arts and Crafts, when it had its home in Regent Street, who worked with Miss

Hosted by Google

Purser. Further on in the paper the author stated that gaols and a distillery had been turned into technical schools. That was somewhat of a triumph. There had been very little reference in the paper to the work of the primary schools. He (the Chairman) did not think there had been a very great change in that respect since he was in Ireland, but one looked forward with great hope in the near future to a great alteration in primary instruction in Ireland. In conclusion, he was glad to notice among the audience a good sprinkling of men who had had to do with the Department's work, and he hoped they would take part in the discussion.

MR. M. J. FLAVIN, M.P., said he was glad of the opportunity, as one who had been connected with technical education in Ireland, to testify to the good work the author and the Chairman had done. His one regret was that Ireland had lost Mr. Blair's valuable services; but that country's loss had been London's gain. The audience had had a real picture of Irish industrial and technical life that night, and he could publicly testify as a Member of Parliament to the great work that had been done, both in agricultural and technical instruction by the Department. All he could say was, "God speed the good work!" He was extremely glad to see that gaols were being converted into technical schools, and he thought that spoke very well for the prosperity, peace, and quietness of Ireland. He did not even regret that a distillery had also been converted. He hoped the good work the Department was doing would progress, as there was plenty of room in Ireland for it.

MR. ALAN S. COLE, C.B., said the constitution of the Board of Agriculture and Technical Education in Ireland had clearly focussed under one administration a number of various forms of aid that were being given previously by the State through different channels; and a great deal of interesting history in connection with them might be gathered from the forty odd annual reports from the old Science and Art Department, in whose service it should always be remembered that many of the greatest men versed in science, art and technical work took part—men like Huxley, Tyndall, Hoffmann, Leighton, William Morris, and many more. Whatever might be the value of their views when compared with those current now, no one would question the indebtedness of the present to the past. In the past, things were in a way possibly more of an experimental character than now. Still, much of the Board of Agriculture's scheme of scholarships, courses of instruction, itinerant teachers, special trade teaching, seemed to him to be direct and wise developments from what existed of a closely similar, if not identical, nature, and to make for a stage beyond experiment. There had obviously been a prolonged activity in the matter of technical education in Ireland, and the Board had in a short time earned a reputation for continuing such activity. After listening to Mr. Fletcher's very lucid and interesting paper, he was sure that it would strike all that the Board, fortunately having his services at command, was pursuing a clear course towards success. The only justification he had for taking part in the discussion was that some years ago he had been called upon to frame and work out some scheme of technical education in favour of lace-making, embroidery and the like in Ireland. That was when he was on the staff of the old Science and Art Department at South Kensington, which Department was approached by certain Irish Members of Parliament interested in the Irish industry of lace-making. For some fifteen years, 1885 to 1900, he visited Ireland usually twice a year, lectured on design, conferred with teachers and pupils, with workers and employers, and he learnt much of the admirable aptitude of the Irish in various cottage or home industries, their versatility, and quickness of appreciation; at the same time regular and ready application of what seemed quickly appreciated was not so apparent to him. That led him to try and get at centres or groups of people engaged in the lace industry where there was something definite in the way of organisation and promise of permanent existence. Many of such centres were at convents, and it was gratifying that a good many of them readily adopted suggestions he was authorised to put before them. They improved their provision to cultivate taste and application, power of design, thoughtfulness and the like, not only in their younger pupils, but also in the adult workers who came to their premises to execute orders for trade purposes. As far as the rules of the Science and Art Department permitted, grants to pay for improved equipment, teaching, and even to build new rooms, were given; and he hoped that the Board of Agriculture found work at these convents to be progressive. He knew that from the point of view of wages and sales in connection with lace-making, Youghal, Kinsale, and Sligo were doing well. But besides the Government grants from the Science and Art Department, funds were provided through the gracious generosity of H.M. the late Queen Victoria, Lady Londonderry, Lady Aberdeen, Mrs. Alfred Morrison, and several others, including a few of the City companies; and by means of these funds a number of experiments were caused to be carried out by adult workers in various parts of the country, whether they were working under committees of private persons benevolently interested, or under convents or traders. Some of the experiments were absolutely successful and notable, some were not; whenever earnest endeavour had been made it was paid for, so that the worker suffered no loss of wage. The influence upon the wage-earning lacemakers was, he thought, valuable. It made them think, and set them to do things which they had not contemplated. Something of that sort was done later on—about

Hosted by Google

1897—in Donegal, by the Congested Districts Board. He was not sure, from what he had heard that evening, whether the Board of Agriculture in Ireland undertook work of the same definite character in touch with wage-earning laceworkers and embroiderers. He realised that it was a form of encouragement that might be held to infringe the doctrine of *laissez faire;* however, in regard to the experiments he had alluded to, he certainly thought that if there were any such infringement it was justified by results, and he hoped that the giving of commissions for the production under efficient check and supervision, of bits of work from prescribed and, if necessary, actually provided designs, might lie within the powers of the Board.

MR. F. G. OGILVIE, C.B., remarked that, since he came to know the work of technical education in Ireland at all intimately, he had always found it to be a work of most absorbing interest, and one which was most fruitful in suggestion; and quite apart from any mere question of what were the details that had been applied in this, that, or the other section of the work—for the sections of the work would have to be counted by hundreds—nothing was more hopeful, within his knowledge of Ireland, than the rapidity with which the Department of Agriculture and Technical Instruction was able to cover the country with a web of most effective educational influences. The work had to be started in almost all the districts of Ireland in so far as it referred to matters connected with trade and industry, other than home industries and those which had been continuously represented in certain large centres. As there were so many sections, it was quite obvious one could not do any more than say that it would be well to look in some detail at the returns and specifications of work done in the different regions. These had been carefully adapted to the special circumstances—the special needs, the special possibilities, and also the special limitations—of the field that had to be occupied. The author had touched upon the work done with regard to the training of teachers. That he (the speaker) considered to be one of the most marvellous, as it was one of the earliest, successes of the Department. Obviously such work in Ireland as had been mentioned in the paper could not have been done unless there had been an adequate corps of teachers. The importation of teachers was reduced to a minimum. It had been kept down by taking a few men of special types and endeavouring to make them centres of instruction. There was one point which had struck him, but which had not been touched upon by the author. He thought not the least important of the results of the work of the Department had been a by-product—the technical education of local authorities in the duties of local government, because he felt sure that the power which was entrusted to the very large number of small committees who had not previously had the opportunity of taking part in local affairs closely related to the welfare of their districts, the assistance given to these in the exercise of that power, and the judgment with which the assistance was given, must have been of the utmost possible value in the development of local responsibility. He had been struck with the rarity of cases of committees acting, as such committees sometimes did act in countries that had long had local government, rather stupidly, or even pig-headedly, or otherwise not for the public good, and he felt that one of the greatest attributes to the excellence of the work done by the Department was the smoothness with which their committees worked, and that their committees did do the work which committees ought to do in the various localities. He was very glad to notice that the work had been progressing in such a way during the years Mr. Fletcher had been wielding the sceptre after Mr. Blair.

MR. E. M. RICH said it had been his duty to look at some of the remaining classes which were conducted under the Science and Art Department in Ireland, and he could assure those present that the difference in the condition of the classes in 1900 in important centres like Belfast and Londonderry, and their condition at the present time was astonishing. One of the very earliest classes he saw was a class in mechanics in Belfast. It was attended by some three or four students sitting in an extremely uncomfortable room, very badly lit, and with practically no apparatus. The audience had seen that night on the screen rooms crammed with artisans. An extraordinary development had taken place in education in Ireland during the last ten years. In conclusion, he might mention that he had spent four years of extremely interesting experiences and great hospitality while he had been resident among the Irish people acting as an inspector of the department.

MR. M. HICKS said he could not help feeling that much of the paper which had been read that evening was of the character that must eventually make for the splendid system of education in Ireland. The author had shown that a good general education had been taken as the basis of the training, and he (the speaker) thought, unless they built on that firm rock, money and time would be wasted, and disappointment would ensue.

MR. GEORGE FLETCHER, in reply, said the remarks which had fallen from the various speakers had made him more painfully conscious than he had been before of many omissions in his paper. He had, however, been bound to omit a great deal. Because he was dealing with technical education he had only referred to the educational work of the agricultural branch, and had not mentioned the Fisheries, or the Statistics, or the Intelligence branches of the Department. He would

Hosted by Google

also have liked to have referred to many of the agencies for assisting teachers, and the loan collections and the numerous exhibitions which had been organised, but all that had to be left out. The Chairman had referred to the stained-glass work in Dublin, and to the bringing over of Mr. Child. He would be glad to learn that Mr. Child was still doing his useful work, and there was an excellent piece of co-ordination in that respect between the Metropolitan School of Art and that little industry. He desired to thank Mr. Flavin for his very kindly remarks. He knew Mr. Flavin's keen and fiery interest in the cause of technical education. Mention had been made of the committees in Ireland. It was not an easy business to meet such committees—they had a way of speaking their mind. But it was worth it. Personally, he had gone through many bad fights with county committees, and he was rather thankful for the experience. One thing he could say truly about the Irish committees, and that was they were perfectly in earnest about their work. It was remarkable in how short a time they got into working order, and there were many examples of most unselfish service to the cause of technical education all over the country. Mr. Cole had raised one interesting point among many, namely, as to whether the Department had maintained any sort of connection with wage-earning workers. It had certainly done so. Happily the Department had very great powers in regard to home industries, and they rather made that a point. They had shut down ruthlessly certain lace classes that were established in urban centres and were of a dilettante nature. The Department aimed definitely at wage-earning in these rural classes. In County Fermanagh there was a very highly-organised system of something like a dozen county teachers of lace, crochet, sprigging and such like. Classes were organised, and they brought in many thousands a year for the workers. There was nothing to prevent the Department from doing that, but it could not give direct aid to industries other than home industries, and those had been rather carefully defined. He ought to say that the Department went just as far as it could in the way of paying for educational training. Mr. Ogilvie was quite right in pointing out the results of the technical education of local authorities. He (the author) was extremely thankful that the Bill was framed on such lines as to make its administration through local committees a necessity. He did not believe the cause of technical education could ever have obtained a hold on public confidence in Ireland unless it had been administered through local committees. With regard to the importation of teachers, that of course was inevitable in the beginning. It followed that, as the work proceeded, Ireland would be able to supply its own teachers. At the present time there were between three and four hundred itinerant teachers engaged over the country under various schemes, and almost without a single exception they were Irish.

The Chairman, in moving a hearty vote of thanks to the author for his interesting paper, said Mr. Fletcher had always had the happy faculty of placing his knowledge before his audience in a very interesting way, and that was one of the faculties which had enabled him to get on so well with the Irish county committees. Mr. Fletcher had what the Englishmen and Scotchmen did not often have, a quick and ready tongue, but with no irony in it; and nothing could be more useful than that before an Irish audience. While taking their work seriously to heart they enjoyed a flavour of humour, and he was bound to say that some of that flavour of humour might help much of the committee work in England.

The vote of thanks was carried unanimously and the meeting terminated.

THE IDEAL HOME EXHIBITION.

At the *Daily Mail's* "Ideal Home Exhibition," at present being held at Olympia, may be seen the conveniently planned "Ideal House," designed by Mr. Reginald C. Fry, in conjunction with Mr. H. Clarke, jun., and erected by Messrs. H. and E. Taylor in the remarkably short period of nine days. Mr. Fry's design and plans, it will be remembered, won the prize in the Ideal Homes Competition, for which nearly 800 architects entered. The house, which has been erected at Olympia at a cost of £1,100, consists of lounge-hall, dining-room, drawing-room, kitchen, scullery, pantry, and cloak-room on the ground floor; and five bedrooms (all with cupboards), bath-room, and dressing-room on the first floor. The servants' bedroom is accessible from the kitchen by a convenient back staircase, and the front door can also be approached from the kitchen through the pantry. Throughout, special attention has been paid to the natural lighting of the various rooms, and the architects have skilfully contrived that all the reception-rooms shall have a south aspect for their principal lighting, while every bedroom has at least one window facing the south-east. In addition to this very popular exhibit there are also erected in the main hall at Olympia the stalls of numerous commercial firms who deal in domestic appliances. Heating, lighting, decorating, furnishing, sanitation, hygiene, cookery, are all represented, and in some cases labour-saving devices, and here inventions or improvements suitable for domestic uses may be seen in actual operation. In the large gallery, in addition to a fairly representative section devoted to the arts and crafts generally, may be found what is perhaps the most interesting feature of the exhibition—a show of modern European furniture, the English section of which has been arranged for the directors by Mr. Dudley Heath. Here can be viewed—necessarily in somewhat confined space—a pleasing series of rooms illustrating the work of some of the

Hosted by Google

best present-day English craftsmen in wood. Among the exhibitors here are Romney Green, Ambrose Heal, Malcolm Powell, Hamilton T. Smith, Charles Spooner and C. F. A. Voysey; and in particular we noticed a wardrobe in English walnut of beautiful design and workmanship by Mr. Hamilton Smith, who also shows an oak side-board of very good appearance and admirably adapted to its purposes. Throughout the whole of this section, even where the design may not appeal, one is uniformly struck by the very high level of the workmanship. The ease with which drawers pull out and in, and cupboards open and shut, might well satisfy the ideals even of the famous eighteenth-century workers. The pieces of furniture (handmade for the most part, although the craftsmen have not hesitated to use machinery where the workmanship did not suffer), too, compare in many cases not unfavourably in price with the machine-made articles of commerce, so that we are surely justified in hoping that the ugliness and bad workmanship to which nineteenth-century methods have made us accustomed, may slowly grow in disrepute.

OBITUARY.

Thomas Colby.—The Society has lost its oldest member by the death, on the 4th inst., at the age of eighty-two, of Mr. Thomas Colby, who became a Life Member of the Society as long ago as 1850. Mr. Colby was a student of the University of Bonn from 1849 to 1852, when he studied chemistry, mathematics and mechanics. He also took part in special magnetic observations at the Bonn Observatory, under Dr. Arzelander. In 1856–7 he patented a process for manufacturing pearl-ash (potassium carbonate) by agitating barium carbonate with potassium sulphate, using large quartz pebbles as a grinding agent in the mixture, which was contained in large wrought-iron revolving drums. The process was carried on at the Posket Nook chemical works, St. Helen's, Lancashire, and the pearl-ash was used at Messrs. Bishop's glass-works for the finer quality of glass. The financial results of the manufactures were, unfortunately, unsatisfactory, and in 1858 Mr. Colby took to farming his own property in South Wales, which he continued to do up till the time of his death.

NOTES ON BOOKS.

On the Backwaters of the Nile. By the Rev. A. L. Kitching, M.A. London: T. Fisher Unwin. 12*s.* 6*d.* net.

Mr. Kitching has spent ten years as a missionary among the outlying tribes of the Uganda Protectorate. He is already known as the author of an outline grammar of the Gan' language, which is spoken by the people who dwell between the Albert Lake and the Victoria Nyanza. He possesses that knowledge of medicine without which no missionary should venture into the wilds; he is a good sportsman, a bit of an architect, carpenter, and handyman; and when it is added that he is a keen photographer and writes in a style which (save for an inordinate passion for splitting his infinitives) is excellent in its terseness and lucidity, it will be seen that he is admirably qualified to give an interesting account of the savage races among whom he has lived so long.

The Gan' appear to be very typical specimens of what Mr. Kitching calls the child races of Central Africa. Living under a tropical sun in a country which provides them with sufficient food at a minimum of labour, they—at all events the men; the women are compelled to do a certain amount of work in order to support their husbands—are among the laziest of mankind. "To be able to say, 'I have no work to do,' is to attain happiness, and no feature of English economy is more incomprehensible to the African mind than the very suggestion of such a measure as a 'Right to Work' Bill." At the same time they are—like most primitive peoples—extraordinary gluttons, and the monotony of their meals, which for the most part consist of millet porridge twice a day, induces such a craving for meat that a special word *amairu* is used to express it, a word which has no equivalent in English. In the pursuit of game—and game must be taken to include such small deer as rats, grasshoppers, and ants—they are capable of enduring great fatigue if there is the prospect of an unlimited gorge at the end of it. The greatest defect of all European meals to the African is that there is not nearly enough. "Quantity, not quality, is what appeals to him, and I have often heard it said that 'Europeans do not know how to eat!' The native expects literally to *feel* full after a good meal, and no worse disgrace could be incurred by a host than to let his guests go away capable of eating another mouthful. The correct condition at the conclusion of a feast was accurately and graphically described by a chief at a native reception to celebrate a European wedding: 'Another morsel would be death!'"

Mr. Kitching has an interesting chapter in which he discusses some of the difficulties in dealing with a language so unlike one's own as the Gan' dialect. "None of the words exactly correspond to English ones, and the words you want most have probably no equivalent at all in the language to be studied. So it frequently happens that the same word will be given you for two ideas apparently inconsistent." Thus in a tentative booklet which Mr. Kitching found in use among the missionaries when he first went into Uganda, God was translated by a word which, as he afterwards discovered, meant "hunchback." Other errors arise through the difficulty of the interpreter, who at first is necessary, to pronounce the words you are studying. A boy of another tribe was endeavouring to carry on a conversation

Hosted by Google

in the Gan' language on the subject of ravenous beasts, including the lion. The Gan' word for lion is *labwor*, but owing to the peculiarities of his own tribal phonetic laws, the boy pronounced this as *labolo*, the Gan' for a banana plant. As the result of this confusion the boy was found to be discussing the possibility of a member of the caravan being carried off in the night by a banana plant.

One of the great characteristics of the young men of the Gan' tribe is their passion for self-adornment. In the almost entire absence of clothes, recourse has to be had to fashions with which Paris and London are unfamiliar. One of the photographs represents three young bloods who have plastered their hair in great chignons, using cowdung as pomatum. Into these all manner of ornaments, such as feathers, hogs' tusks, and metal rings, are thrust. A bit of looking-glass is frequently worn on the forehead, and happy is the youth who can thrust a pencil of glass through his underlip. But perhaps the most remarkable adornments are the tight bracelets of metal which you must wear if you would be a blood. No lady of fashion in Europe was ever called upon to endure the agonies which these bracelets cause. So tight are they that arms are often ulcerated, and muscles distorted for life; indeed, Mr. Kitching describes one terrible case in which two iron rings, each an inch thick and perhaps two pounds in weight, had become buried in the flesh so as to be partly invisible. The pain that must have been caused for years before such a state of things could have become possible is almost inconceivable.

It has been mentioned that among the Gan' clothes are almost unknown. Cheap calico trousers have, however, made their appearance during recent years, though they are not always worn in the fashion usual in civilised countries. If a native is on a journey, he will very probably wrap them round his neck, partly in order to save them, partly, no doubt, because it is more comfortable to walk in a state of nature. They have other uses, too. If the ends of the legs are tied up, the trousers make an excellent double sack, very convenient for carrying flour, etc.

Mr. Kitching has written a very complete and graphic account of the Gan' people; the book is illustrated by nearly sixty photographs taken by himself, and a good map, and it will be read with keen interest by all those who take pleasure in the study of primitive races.

A B C OF HYDRODYNAMICS. By Lieut.-Colonel R. de Villamil, R.Eng. (retired). London: E. & F. N. Spon, Ltd. 6*s*. net.

In this book the author hopes to be able to relieve the beginner of difficulties which would otherwise beset him in his study of hydrodynamics. His aim is to show that ordinary liquids follow the same laws as the "perfect liquid" of the text-books, and under similar conditions move in a similar manner. The beginner who has here his A B C is supposed to have proceeded some way in the reading of the usual text-book. The scheme of the book involves its author in a large amount of quotation, which must either require in the conscientious reader a continual reference to his authorities or imply in him a knowledge of the subject distinctly beyond the A B C. Yet Colonel de Villamil has given us an introduction dealing with the first principles of hydrodynamics which cannot fail to engage the attention of the student. Whether he may eventually prove to have simplified his subject or not, it must be said that at some points he suggests attractive explanations. To take a slight example, in the chapter on a viscous fluid flowing "by obligation" there is outlined what he considers may be the first stage in the formation of vortices; the diagram given by Lord Kelvin in his paper on "Coreless Vortices" being the second stage.

The summary given at the close of each chapter is a decided advantage to the reader, who too rarely finds such consideration.

GENERAL NOTES.

THE INSTITUTE OF METALS.—The third May lecture of the Institute of Metals will be delivered at the Institution of Mechanical Engineers, on May 10th, by Sir J. Alfred Ewing, K.C.B., F R.S., the subject being "The Inner Structure of Simple Metals." The chair will be taken by Professor W. Gowland, F.R.S., President of the Institute. Members of the Royal Society of Arts who desire to be present should apply for tickets to Mr. G. Shaw Scott, M.Sc., Secretary, Institute of Metals, Caxton House, Westminster, S.W.

THE HARVEST OF CEREALS IN ALGERIA, 1911.—The returns showing the results of last year's harvest in Algeria have just been published by the Government of that colony. They show a shortage in the wheat crop of 953,000 quintals (1,875,984 cwts.), as compared with that of 1910, which was an exceptionally good one. The total production last year was 9,763,000 quintals (19,218,504 cwts.) against 10,716,000 quintals (20,094,488 cwts.) in 1910. The production of barley during 1911 was slightly inferior to that of 1910, being 10,361,000 quintals (20,395,669 cwts.) and 10,605,000 quintals (20,875,984 cwts.) respectively. The quantity of oats grown in the colony was small, when compared with that of the wheat and barley, being 1,692,000 quintals (3,330,708 cwts.) only.

MEXICAN VANILLA.—As far back as the time of the Aztecs the vanilla was used to spice the chocolate. Vanilla, or, as the Spanish word is spelt, "vainilla," is a kind of climbing tropical orchid with thick leaves, and spikes of large and not very beautiful flowers. The Spaniards, quick to see the value of vanilla as

Hosted by Google

an article of export, began the cultivation of the aromatic pod. For a long time the former province of Vera Cruz supplied the whole world with vanilla, until the Bourbon Islands and Java waged competition against it. The vanilla of Mexico is the superior of all other varieties as to aroma, and the pod yields a much larger quantity of essential oil. In the markets of the United States about one fourth of the imports of vanilla beans comes from Mexico, at two or three times the price paid for the product of other countries. Vanilla is to a large extent cultivated in plantations, on damp but not swampy or muddy lands, in the tropics, where the necessary shade can be secured, a condition found in all the States contiguous to the Isthmus of Tehuantepec. The plant begins to yield thirty-nine months after planting, and continues to yield during ten to twelve years. The average yield is from ten to twenty pods to a vine, artificial fertilisation producing much more. The cultivation of vanilla has many advantages, among others the fact that corn crops can be grown in conjunction with it, while on coffee plantations it can be made to play a secondary but profitable part.

Bulletins of the International Institute of Agriculture. — The Society has received, through the kindness of the Board of Agriculture and Fisheries, eight volumes of the Bulletins published by the International Institute of Agriculture, Rome. Three of these are issued by the Bureau of Agricultural Intelligence and of Plant Diseases, and five by the Bureau of Economic and Social Intelligence. The intelligence contained in each volume is taken exclusively from the books, periodicals, bulletins, and other publications which reach the Library of the International Institute of Agriculture during the period covered by the volume. It is thus gathered from an immense number of sources, not a few of the articles being reprinted from this *Journal*. The edition which has been received by the Society is entirely in English, articles from French, German, Italian and other foreign publications having been translated by translators attached to the Bureau. The information contained in the bulletins is of a very varied description, and the publications should prove of great value to all interested in agriculture.

Cotton Cultivation in Turkestan. — The Russian Government has been assisting in many ways the growers of Trans-Caspian cotton. It appears from official reports that, in the autumn of 1910, the Agricultural Department organised the first cotton-seed plantation in Turkestan. In 1911 one such station was working in the Namangansk district of the Ferghana Oblast, covering an area of 53 dessiatines (about 143 acres). Here three systems of cultivation were applied. First, by machinery only, the seeds being sown in rows, and the soil between the rows ploughed; secondly, by using both machinery and hand labour for sowing, but working the soil between the rows; thirdly, by manual labour only, the natives being employed. The best results from the point of view of an abundant crop were achieved by relying entirely on machinery, the results being 8,613 pounds per dessiatine (2·7 acres) for machinery, 5,556 pounds for machinery and labour and 4,921 pounds for hand labour alone. Manure was used in the first instance only. The average crop of cotton obtained on the plantation amounted to 3,692 pounds per dessiatine, but a second crop of 540 to 720 pounds is expected, so that the average for the station for 1911 may be estimated at about 4,300 pounds.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

May 1. — William Burton, M.A., F.C.S., "Ancient Egyptian Ceramics." Charles Hercules Read, LL.D., President of the Society of Antiquaries, and Keeper of the Department of British and Mediæval Antiquities and Ethnography at the British Museum, will preside.

May 8.—E. D. Morel, "British Rule in Nigeria." Sir Edouard Percy C. Girouard, R.E., K.C.M.G., D.S.O., late Governor of Northern Nigeria (1908–9), and of the East African Protectorate (1909–12), will preside.

May 15. — Ernest Kilburn Scott, Assoc. M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere." Sir William Ramsay, K.C.B., Nobel Laureate, F.R.S., will preside.

May 22. — Gordon Craig, "Art of the Theatre." Miss Ellen Terry will preside.

Indian Section.

Thursday afternoon, at 4.30 o'clock:—

May 16.—Neville Priestley, Managing Director, South Indian Railway, "Indian Railways."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

May 7.—Alan Burgoyne, M.P., "Colonial Vine Culture."

May 21.—The Hon. J. G. Jenkins, "Australian Railways."

Howard Lectures.

Monday evenings, at 8 o'clock:—

Captain H. Riall Sankey, R.E. (retired), M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

Syllabus.

Lecture I.—April 29.—The oil engine is an internal combustion engine—Difference between light and heavy oil engines—Difference between Diesel and other heavy oil engines—Brief history

Hosted by Google

of the Diesel engine—Theoretical thermal efficiency—Heat and other losses—Actual thermal efficiency—Efficiency ratio—Thermal efficiency compared with other internal combustion engines and with external combustion engines—Cycle of operation of a 4-stroke and of a 2-stroke Diesel engine, and essential parts to produce these cycles.

LECTURE II.—MAY 6.—Various types of Diesel engines—Considerations affecting design—Design of various parts, such as cylinders, valves, pistons, connecting rods, crank shafts, frames, air compressors, etc., for 4-cycle and for 2-cycle engines—Materials used for the various parts—Number and arrangement of cylinders for vertical and horizontal engines.

LECTURE III.—MAY 13.—Description of Diesel engines manufactured by various makers—Sizes in current manufacture and future possibilities—Speeds and weight for land and marine engines—Various kinds of oil available for Diesel engines; their characteristics, calorific value, and sources of supply.

LECTURE IV.—MAY 20.—Economical results in respect of fuel and of total annual cost—Comparison of Diesel, gas and steam engines, in respect of capital cost, fuel cost, and total annual cost—Various applications to land and marine purposes—Other heavy oil engines—Semi-Diesel engines.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 29...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Howard Lecture.) Captain H. R. Sankey, "Heavy Oil Engines." (Lecture I.)

Aeronautical Society, at the Royal United Service Institution, Whitehall, S.W., 8.30 p.m. Captain C. H. Ley, "Aerial Topography."

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. G. T. Loban, "Some Principles in the Valuation of Land and Buildings."

Actuaries, Staples Inn Hall, Holborn, W.C., 5 p.m. 1. Messrs. H. W. Manly and T. G. Ackland, "On the Superannuation and Pension Funds of certain Metropolitan Borough Councils, their Establishment, Administration, and Actuarial Investigation." 2. Mr. L. E. Clinton, "Tables of Progress of Typical Funds for Officers and Workmen, and Examples."

TUESDAY, APRIL 30...Sociological, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Mr. Graham Wallas, "Syndicalism."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. F. B. Brown, "Insect Distribution, with special reference to the British Isles." (Lecture I.)

Economics and Political Science, London School of, Clare-market, W.C., 6 p.m. Professor H. Levy, "Die Volkswirtschaftliche Entwicklung Englands und Deutschlands" (in German). (Lecture I.)

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. F. W. Fincham, "Mont St. Michael, the Abbey of the Archangel and its Sea-girt Town."

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Annual General Meeting.

WEDNESDAY, MAY 1...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. W. Burton, "Ancient Egyptian Ceramics."

Geological, Burlington House, W., 8 p.m.

Public Analysts, at the Chemical Society, Burlington House, W., 8 p.m. 1. Messrs. W. L. Austin and C. A. Keane, "The Analysis of Lithopone." 2. Messrs. C. O. Bannister and W. McNamara, "The Effect of Calcium on the Ammonium Molybdate Lead Assay." 3. Messrs. J. W. Agnew and R. B. Croad, "The Constituents of Oil of Savin." 4. Mr. W. B. Pollard, "The Detection of Heavy Petroleum in Paints and Vegetable Oils."

United Service Institution, Whitehall, S.W., 3 p.m. Captain R. J. Kentish, "The Case for the Eight-Company Battalion."

Royal Archæological, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Dr. A. C. Fryer, "The Monumental Effigies of Nicholas Stone."

Economics and Political Science, London School of, Clare-market, W.C., 5 p.m. Hon. W. P. Reeves, "Land Taxation in relation to Land Tenure in Australasia."

Royal Institution, Albemarle-street, W., 5 p.m. Annual Meeting.

THURSDAY, MAY 2...Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Linnean, Burlington House, W., 8 p.m. 1. Miss T. L. Prankerd, "The Structure of the Palæozoic seed *Lagenostoma ovoides*, Will." 2. Dr. Karl Domin, "Additions to the Flora of Western and North-Western Australia." 3. Mr. G. H. Wailes, "Freshwater Rhizopoda from the States of New York, New Jersey, and Georgia, U.S.A.; with a Supplement on a Collection from the Seychelles." 4. Mr. W. M. Webb, "*Ligidium hypnorum*, a Woodlouse new to Britain." 5. The General Secretary, "New Light on the Linnean Herbarium."

Chemical, Burlington House, W., 8.30 p.m. 1. Messrs. F. H. Carr and W. C. Reynolds, "Nor-hyoscyamine and nor-atropine. Alkaloids occurring in various Solanaceous Plants." 2. Mr. A. H. Salway, "Researches on the Constitution of Physostigmine." (Part I.) 3. Mr. T. S. Moore, "The 'true' Ionisation and Hydration Constants of Ammonia and some Amines, with a Note on the Formulation of Nitrogen Compounds."

Royal Institution, Albemarle-street, W., 3 p.m. Professor J. Norman Collie, "Recent Explorations in the Canadian Rocky Mountains." (Lecture I.)

Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Adjourned discussion on "The Causes Preventing the More General Use of Electricity for Domestic Purposes."

Economics and Political Science, London School of, Clare-market, W.C., 3 p.m. Miss Barbara Freire-Marreco, "The Self-Government of the Pueblo Indians under Spanish and American Administration." (Lecture I.) 5 p.m. Miss Mabel Atkinson, "The Consumption of Wealth in the Different Sections of the Community." (Lecture I.)

FRIDAY, MAY 3...Royal Institution, Albemarle-st., W., 9 p.m. Mr. W. C. D. Whetham, "The Use of Pedigrees."

Economics and Political Science, London School of, Clare-market, W.C., 5 p.m. Professor J. H. Morgan, "The Legal Basis of the Government of England and Ireland." (Lecture I.)

Mechanical Engineers, Storey's-gate, Westminster, S.W., 8 p.m. Discussion to be opened by Professor J. O. Arnold on "The Tenth Report to the Alloys Research Committee on the Alloys of Aluminium and Zinc."

SATURDAY, MAY 4...Economics and Political Science, London School of, Clare-market, W.C., 12 noon. Dr. C. Bougle, "Les Etapes du Mouvement Social en France au Dix-Neuvième Siècle" (in French). (Lecture I.)

Royal Institution, Albemarle-street, W., 3 p.m. Mr. R. Blomfield, "The Architecture of the Renaissance in France." Lecture III.—1594-1661. Architecture and France."

Municipal and County Engineers, Public Hall, Exmouth, 11 a.m. (South-Western District Meeting.) Mr. S. Hutton, "A Decade of Progress in a Residential Seaside Town."

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,102. VOL. LX.

FRIDAY, MAY 3, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MAY 6th, 8 p.m. (Howard Lecture.) CAPTAIN H. RIALL SANKEY, R.E. (retired), M.Inst.C.E., "Heavy Oil Engines." (Lecture II.)

TUESDAY, MAY 7th, 4.30 p.m. (Colonial Section.) ALAN BURGOYNE, M.P., "Colonial Vine Culture." THE RIGHT HON. SIR WALTER HELY-HUTCHINSON, G.C.M.G., late Governor of Cape Colony, will preside.

WEDNESDAY, MAY 8th, 8 p.m. (Ordinary Meeting.) E. D. MOREL, "British Rule in Nigeria." SIR EDOUARD PERCY C. GIROUARD, R.E., K.C.M.G., D.S.O., Governor of Northern Nigeria (1908–9), and of the East African Protectorate (1909–12), will preside.

Further details of the Society's meetings will be found at the end of this number.

HOWARD LECTURE.

On Monday evening, April 29th, CAPTAIN H. RIALL SANKEY, R.E. (retired), M.Inst.C.E., delivered the first lecture of his course on "Heavy Oil Engines."

The lectures will be published in the *Journal* during the summer recess.

PROCEEDINGS OF THE SOCIETY.

NINETEENTH ORDINARY MEETING.

Wednesday, May 1st, 1912; CHARLES HERCULES READ, LL.D., President of the Society of Antiquaries, and Keeper of the Department of British and Mediæval Antiquities and Ethnography at the British Museum, in the chair.

The following candidates were proposed for election as members of the Society:—

Dubash Kader Sahib, Khan Bahadur D.K., Abiraman-Natham, Ramnad District, Madras, South India.

Gordon, Duncan Macdonald, Keng Tung, Southern Shan States, Burma.

Harris, Thomas J., Botanic Station, Bermuda.

Morris, James, jun., Westdene, Ashburton-road, Birkenhead.

Neely, David Bradley, M.D., M.P., Humboldt, Saskatchewan, Canada.

Rutton, B. N., B.A., The Mall, Lahore, India.

Seabrook, Bagster Roads, P.O. Box 96, Toronto, Canada.

Seabrook, Norman Bagster, P.O. Box 96, Toronto, Canada.

Wakefield, William Birkbeck, Wilcot, Bisley, Surrey.

The following candidates were balloted for and duly elected members of the Society:—

Archer, Captain F., Main-road, Akyab, Burma.

Astley, Rev. Hugh John Dukinfield, M.A., Litt.D., The Vicarage, East Rudham, Norfolk.

Barnes, Charles A. Albert, Assoc.M.Inst.C.E., Government Survey Schools, Lagos, West Africa.

Eades, C. T., Beech-grove, Cheshom Bois, Bucks.

Jasonidy, Onuphrius John's, Blondel-street and Empress Ireni-street, Limassol, Cyprus.

Jones, Bassett, Jun., 1, Madison-avenue, New York City, U.S.A.

Laut, Miss Agnes C., Wassaic, Duchess County, New York, U.S.A.

Line, Charles Arthur, 39, Beaufort-road, Edgbaston, Birmingham.

Mackinney, Valentine Henry, Deancot, 85, Woodstock-avenue, Golder's Green, N.W.

O'Connor, H. J. Courtenay, Limehayes, Killyon-road, Larkhall-rise, S.W., and Bathurst, Gambia, West Africa.

Hosted by Google

Robins, Herbert George, c/o Tanganyika Concessions, Ltd., Lulua Poste, via Elizabethville, Katanga, Belgian Congo.

Skrimshire, Alfred J., 31, Ryde Vale-road, Balham, S.W.

Weir, Charles James, Moorcroft, Silvermere, Cobham.

The paper read was—

ANCIENT EGYPTIAN CERAMICS.

By William Burton, M.A., F.C.S.

This is essentially an age of discovery, but it is likewise an age for the revision of past theories. Such a statement is particularly true of our knowledge of ancient pottery; for while, on the one hand, we find the archæologist studying every modern craft in order to obtain hints as to ancient methods, on the other hand we have many modern craftsmen keen enough about the development of their own craft who are able to throw light on the work of their fellows in remote antiquity. As such a craftsman, therefore, and not as an Egyptologist who finds valuable material in the commonest potsherds for his reconstruction of an ancient civilisation, I venture to address you.

It seems to me that too much has been made of the unglazed Egyptian pottery of every period. The ordinary red, buff, or brown pottery — evidently manufactured for the simpler domestic uses, and largely for the common people—has little to say for itself from the potter's point of view, however valuable it may be as material for sequence-dating to the student of history. It presents no essential difference, either in material or manufacture, from other forms of primitive pottery, whether of ancient or modern times. Its shapes, though characteristic, can hardly be called distinguished, and they have exercised comparatively little influence on the subsequent development of the potter's art in other countries. Compared with the early pottery of other great races, like the Greeks, Persians, or Chinese, the origin of which is almost as remote, the ordinary unglazed Egyptian pottery occupies a very secondary position. The only exception I should make to this statement is the red ware with shining black mouths, belonging to pre-dynastic times. It is quite otherwise, however, when we consider its ancient glazed wares dating from early dynastic or pre-dynastic times, with their brilliant turquoise colours of green or blue shade—colours which, if not unrivalled, have at all events remained unsurpassed through all the centuries. European scholars during the past century or so have described this glazed ware as "Egyptian Porcelain" or as "Glazed Faience." The reason for this terminology is not far to seek, in fact it is crystallised in Brogniart s famous "Traité des Arts Céramiques," to which the antiquary of our day generally refers with as much confidence as if it had been published yesterday. Honouring Brogniart, as we do, as the pioneer who first tried to reduce all that had been done in pottery to a system, it is only fair to point out that the foundation of a knowledge of pottery which may reasonably be called scientific, has arisen since Brogniart died. To-day we may say safely that the basal material of pottery of any kind is one of the natural clays, and that we cannot conceive the existence of a kind of pottery which does not contain some form of clay as an essential ingredient. If, however, it can be proved that the brilliantly glazed wares of the Egyptians did not contain clay as an essential ingredient of their substance, we must abandon the use of the names "porcelain" or "faience," that have hitherto been used to describe them. But how are we to settle, at this distant date, the nature of the material from which these beautiful objects were fashioned? In the first place we have, of course, the aid of chemical analysis, and the following table presents the most reliable analyses of the body of this Egyptian glazed ware that I have been able to obtain from objects of the various periods :—

	1.	2.	3.
Silica	94·00	94·18	94·18
Alumina . . .	1·80	0·59	1·93
Oxide of Iron . .	0·89	1·64	0·28
Lime	2·00	1·73	1·60
Magnesia . . .	1·05	1·82	0·05
Alkalis	0·25	—	1·11
Loss on ignition .	0·11	0·04	1·00

It will be seen that these analyses, in spite of minor variations, are remarkably constant in

Hosted by Google

their main constituent, *viz.*, silica, and the first question we have to ask ourselves is how such a material could have been obtained by a mixture of natural substances. But to Brogniart and his contemporaries who, as it appears to me, were handicapped by the idea that the material *must* be a form of pottery, the figures given by chemical analysis could only be explained on the supposition that a large proportion of sand had been mixed with a very small proportion of clay to make the substance in question, and no one seems to have inquired whether such a mixture would possess the necessary plasticity to enable it to be fashioned by the general methods of the potter. After having tried many mixtures of the kind indicated by these analyses, I have been forced to the conclusion that the small amount of clay indicated by the percentage of alumina found would be entirely insufficient to give a material that could be shaped by pottery methods, and we have, therefore, to search for some other explanation of the general composition of the material used by the ancient Egyptians. It has been recognised for some time that the analyses given above would correspond roughly with the analyses of many ordinary sandstone and quartzite rocks, and my researches have satisfied me that the ancient Egyptians used some natural sandstone from which they carved the objects that have been so freely found in the tombs glazed with these brilliant glazes. It may perhaps be interesting if I indicate how this view has gradually arisen in my mind, because that may serve as another instance of the reluctance with which most of us depart from generally accepted views. When I first commenced to study pottery, the art of the ancient Egyptians was quite remote from my path, and I therefore accepted the views that I found put forward in the most authoritative books, and assumed, without question, that the glazed objects could be made by mixing a very little clay with a large percentage of sand. Like other students, I did not appreciate the fact that the earliest glazed objects recovered from Egyptian tombs comprise small scarabs, beads, necklace pendants, and such like things, carved in schist, steatite, and even in harder minerals, like rock crystal. In that fact there was a hint which ought to have led past observers to a sound view of this question long ago. The generally accepted view among Egyptologists to-day is that the blue or green glazes first appeared on objects carved from natural stones, and, remembering the conservative nature of the early Egyptian people, it seems to me natural that some soft sandstone should have been finally settled upon as the material particularly adapted to these especial glazes. I may be reminded that large tiles, glazed all over, were used to line the walls of tombs in early dynastic times, but I must point out that the carving of flat tiles from natural sandstone, and the application of turquoise glazes to them, is an art that has persisted to modern times. We find, for instance, that many of the tiles used for decorating the mosques and tombs in India and Central Asia, long after the ancient Egyptian civilisation had expired, were simply slabs of carved sandstone, and this craft represents the survival of a technical method used by the Egyptians as early as the First Dynasty. A consideration of the forms used in the early objects of turquoise glaze, whether green or blue, that have been recovered from tombs, will support the view that they were carved from some form of natural stone, and not, as most authorities have stated, thrown on the potter's wheel.

[Here a number of slides were shown of objects from the XIIth Dynasty down to Roman times, in which the technique was that of carving in fairly soft material, and not characteristic of objects shaped from plastic clay.]

In addition to the evidence of chemical analysis, and of technical methods of carving, we have a more complete and satisfactory test available. We may, for instance, treat these Egyptian glazed figures as a petrologist would treat an unknown rock to determine its structure and the nature of its constituents, and as I have from time to time obtained specimens of such material, which can be dated with reasonable accuracy, I have had prepared a number of thin slices which can be examined by all the well-known methods of microscopic examination with polarized light, etc., and the evidence furnished completely confirms the view that the Egyptians must have used a kind of sandstone, or quartzite, for their glazed objects, and not a substance containing any appreciable amount of clay. Of course, the number of specimens that I have been able to sacrifice in this way to scientific research is not very great, but in all the specimens I have examined, from the time of the XVIIIth Dynasty down to that of the Roman occupation, I find the general use of some natural siliceous rock.

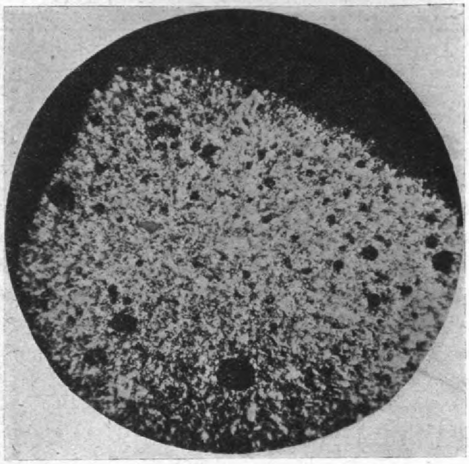

FIG. 1.—SECTION OF USHABTI FIGURE, XVIIITH DYNASTY. CROSSED NICOLS.

once seen to be eminently characteristic. The material consists of fine, sharp grains of quartz mixed with a few opaque particles of magnetic oxide of iron, but with no trace of any clay substance. Similar sections from a figure dating from the XXVth or XXVIth Dynasty, and from a little figure of the god Bes, which is probably as late as Roman times, reveal a similar structure, so that this series proves the existence of an unaltered technique, at all events for objects of certain kinds, for a period of at least 1500 years, at the very time when change was more rife in Egyptian methods than in the previous 2000 years. A comparison of such preparations with others made from typical objects of porcelain or pottery shows the profound difference made in the material by the introduction of a considerable proportion of clay.

Fig. 2 represents a slice of Chinese porcelain cut from a specimen sent to me some years ago by the late Dr. Bushell as an authentic fragment of Sung porcelain, as he had himself disinterred it from the rubbish mounds that mark the site of the ruins of the ancient Pekin destroyed by Kublai Khan in the thirteenth century. The difference between this material and the ancient Egyptian is strongly marked. Instead of finding the whole substance a mass of crystalline grains that can be readily identified by means of their reaction with polarized light, we have a granular amorphous material which does not react with polarized light, and scattered through this a number of crystalline specks which we can identify as the remains of the quartz and felspar crystals that were mixed with the china clay to form the body of the porcelain, and have not been entirely combined with it.

Fig. 3 is a section of a typical modern earthenware—an ordinary tile manufactured by my firm and taken casually from stock—and it exhibits a structure quite analogous to porcelain; except that, as we might expect, the modern mechanical methods used in preparing the ingredients of our pottery have produced a finer and more homogeneous substance than the ancient porcelain.[1]

This new evidence, which so conclusively supports the views already advanced, warrants us therefore in definitely separating the ancient Egyptian material from pottery, and I venture to propose that it ought to be described as "Glazed Siliceous Ware," for such a title would include all the objects carved from natural stones whether they be schist, steatite, diorite, rock crystal, or sandstone.

A further point of great interest is clearly established by the microscopic examination of these thin slices. Many observers have already pointed out that the ancient Egyptian material owed its strength to the glaze and not to the

FIG. 2.—SECTION OF SUNG PORCELAIN. UNDER CROSSED NICOLS.

body. In fact where such objects have been buried in situations where the glaze has been decomposed, the body became a soft and friable mass that could, as a rule, be readily powdered

Hosted by Google

between the fingers, a state of affairs that does not take place with pottery. When slices of pottery and porcelain are examined microscopically, the glaze is always found as a

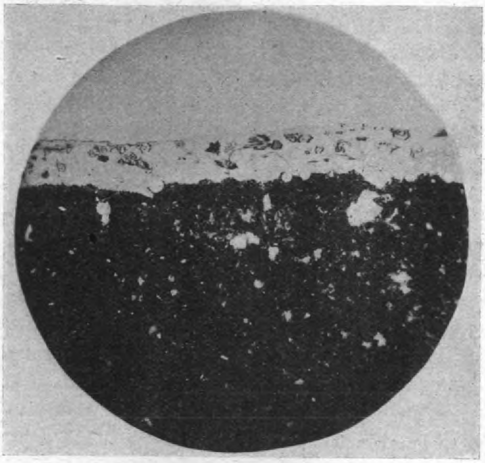

FIG. 3.—SECTION OF EARTHENWARE WITH CRYSTALLINE GLAZE. UNDER CROSSED NICOLS.

definite coating of glass of appreciable thickness, resting on the body material. We may return to our sections of Chinese porcelain and of English earthenware, Fig. 4 and Fig. 5, and, if we examine them under ordinary light, the glaze layer is readily distinguished from the close-grained amorphous body, which is, of course, much more opaque than the glaze. Fig. 6 represents a specimen of the Egyptian ware, and the difference is at once striking and characteristic. The glaze does not form a definite glassy layer resting on the body, but is seen to have sunk in or eaten its way in between the grains of quartz, so that we obtain a hard skin, in which the body grains can be clearly distinguished embedded in and partly dissolved by the glaze. As the glaze is strongly coloured it looks dark against the mass of the body—the very reverse of what we find with the glazes of pottery and porcelain. This action between the glaze and the crystalline grains of the body also enables us to explain a fact frequently commented on, that where hard minerals, like rock-crystal or diorite, have been glazed and the glaze has been worn off, the mineral is always found to present a pitted surface, showing where it has been attacked and partly dissolved by the glaze.

As to the nature of these earliest glazes, they are always found to consist essentially of silicates of the alkalies and lime coloured with oxide of copper—differing therefore from ordinary pottery glazes in containing no appreciable amount of alumina or of oxide of lead. Such glazes will only melt to a decent surface on materials very rich in silica, and any attempt to apply them to the surface of ordinary pottery fails disastrously, for on such a surface they yield only an irregular, puckered, mass.

Professor Eliott Smith, in his masterly little sketch, "The Ancient Egyptians," claims that one of the glories of the Nilotic peoples was their early discovery and use of metallic copper. He suggests that the first metallic copper may have been accidentally produced by some Egyptian woman dropping her earring of malachite into a charcoal fire. I would remind you of the passionate admiration shown by the ancient Egyptians for the beautiful blue and green stones, lapis-lazuli, turquoise, and malachite. All these stones were so highly prized as gem stones that we cannot wonder that any accident should have set the minds of these ingenious people at work towards their imitation at a very remote date, and it is at all events significant that the first coloured glaze or enamel that made its appearance, so far as we know, in the world is this wonderful blue or green turquoise glaze which owes its colour to copper, and to copper only. This art of glazing or enamelling on stone appears to me

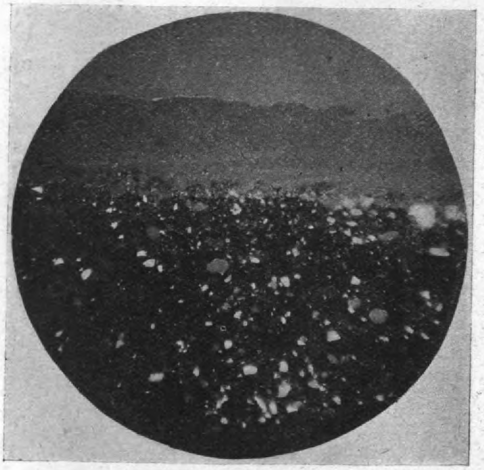

FIG. 4.—SECTION OF SUNG PORCELAIN. ORDINARY LIGHT.

to have arisen as a branch of the art of the jeweller and goldsmith, and not of the art of the potter, for the objects fabricated, down to the end of the XIIth Dynasty at all events,

Hosted by Google

were for the most part small in size, and adapted only for use as jewellery, as personal adornment, or as adjuncts to the toilette. They consist almost exclusively of beads,

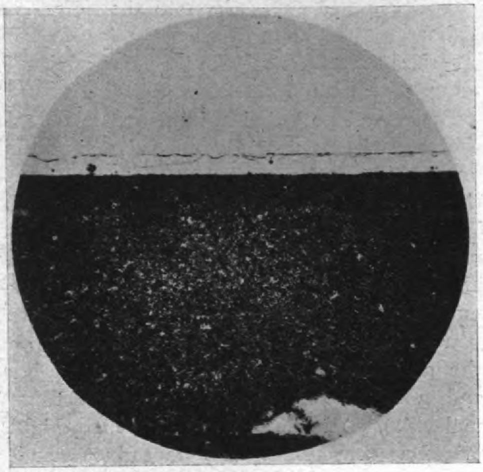

FIG. 5.—SECTION OF MODERN EARTHENWARE. ORDINARY LIGHT.

scarabs, rings, seals, badges, pectoral plates, etc., all having a close affinity in style to contemporary goldwork or jewellery, and presenting no resemblance to the contemporary work of the potter in common clay. Even when vase forms appear they are of small size (the Tuneh cups, etc.), and their shapes and outlines are derived, as I have said, from those common in carved stone, while they have no resemblance to the contemporary shapes of ordinary pottery. If my theory be correct then we reach another important point, viz., that the discovery of this art of enamelling on objects carved in various stones, including sandstone, did not follow the discovery of the art of making glass, but was really the *fons et origo* of glass, of enamelling on metal, and of pottery glaze. This view is supported by the nature of the earliest objects of *cloisonné* work, in which beautiful coloured stones such as lapis-lazuli, green felspar and carnelian were freely used many centuries before the use of coloured glass pastes. The real order in which the different fusible artificial silicates made their appearance at all events in Egypt (though probably not in other countries) appears to be, (1) blue or green turquoise glaze on stone objects, (2) glass paste, (3) glass wares made in the Egyptian fashion (not by blowing).

We have still to account, however, for the successive steps by which glazes of analogous composition were ultimately used on pottery vessels made from clay, by interposing between the clay and the glaze a thin layer of slip exceedingly rich in silica. For the present the evidence on this head is far from definite or complete. In late Roman times, and immediately on the Arab occupation, we find an extensive manufacture of Egyptian pottery made in this way, but we are in doubt as to when the practice originated, and whether on its first appearance this method supplanted the older method or whether, as seems to me more probable, the two methods went on side by side for some centuries, the earlier method being used for small traditional objects, especially those connected with religious rites and ceremonies, and the newer method gradually making its way by the development of larger and more ambitious vase forms. In this connection we have the fact that the Persian potters, contemporary with the close of the Egyptian dynasties, manufactured both tiles and vases coated with a sandy face and glazed with blue and green glazes analogous to the Egyptian ones. It may be that they acquired this knowledge from their occupation of Egypt during the time of Cambyses and his successors, though this is hardly more than a probable guess, and until a large series of dated objects has been examined by the means described in this paper we shall be unable to form any very definite conclusion as to the date of the new method which bridged

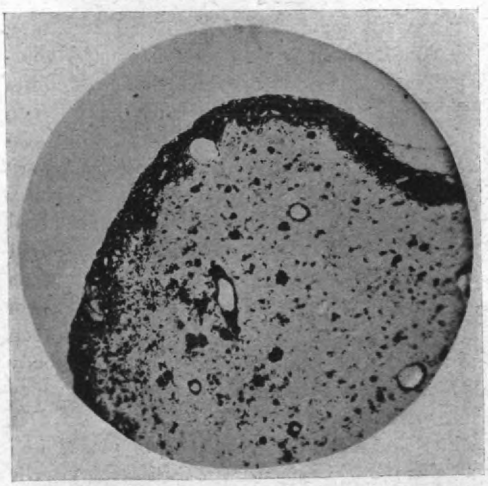

FIG. 6.—SECTION OF FIGURE OF GOD BES. ROMAN PERIOD. ORDINARY LIGHT.

over the gap between the "glazed siliceous wares" and Egyptian glazed pottery. Since the highly siliceous character of the early glazed wares has been more clearly recognised

Hosted by Google

by Egyptologists, and it was realised that some alternative must be found for the belief in a mixture of sand with a small percentage of clay to give it plasticity, the suggestion has been made that the objects I believe to have been carved in sandstone were really modelled in sand, held together, and made sufficiently workable to be moulded, by the addition of some fatty or mucilaginous material. Such organic substances would be destroyed and disappear in the early stages of the firing, and then, of course, the glaze would hold the grains of sand together in the way already shown. This method may have been used for making the wares of the XXVth and later Dynasties, in which the whole composition appears to be a mixture of sand and glaze, but it can hardly have been in general use with sand alone, for though I have with considerable difficulty succeeded in making a few small glazed figures by this method, they are softer and more rotten in body than any Egyptian glazed objects I have ever handled.

In closing this account of ancient technical methods, which can only be regarded as tentative and suggestive pending the examination of a much greater number of dated specimens, I must mention one of the later technical developments which is of great interest. All Egyptologists are familiar with the incised ushabti figures of the XXVIth Dynasty just referred to, which are found in such amazing quantities in the tombs of that epoch. These ushabtis are denser and harder in substance than those of previous dynasties, they possess very little gloss, and are of a pale greenish-blue colour, which is found to be fairly uniform throughout the mass. There can be no doubt that these were made in moulds, the lines being sharpened up by hand if necessary, and it is perfectly clear that the composition, a mixture of sand and the turquoise frit or glaze, was uniform throughout, that there was no final coating of glaze applied to the surface, and further that such wares were fired to a higher temperature than that used for the ordinary glazed objects. French writers have not hesitated to describe this material as "porcelain," citing the fact that the earliest French porcelains of the seventeenth and eighteenth centuries, and the Florentine porcelain of the late sixteenth century, were made by mixing a large proportion of glass with the other ingredients. If such a material as that of these XXVIth Dynasty ushabtis is to be spoken of as porcelain, then we should have to acclaim these Egyptians as the first makers of porcelain in the world, for Chinese porcelain—the true porcelain *par excellence*—did not make its appearance for many centuries later. But the basal argument of this paper is that no substance can be rightly described as porcelain or pottery unless clay is an essential ingredient. These ushabtis do not contain any clay, and therefore I should not describe them as porcelain, but as "fritted siliceous ware," in contradistinction to the "glazed siliceous wares" of other days.

The most astonishing use of glass or glaze in the body of pottery is probably later still in date, apparently of Ptolemaic or Roman times, for a few small bowls have been found, glazed with the more glassy and transparent blue glaze of the late period, which are strongly marbled, as if made in imitation of a dark-blue veined onyx. When such pieces are held up to the light it is found that the marbling is produced by the introduction of fragments of a deep-coloured turquoise glaze in the material, so that the sides of the bowl appear set with blue windows.

I have chosen to speak only of the turquoise glazes because they are the most characteristic, and are the only ones that occur in every period, from the earliest to the latest. The white and polychrome glazes that began to make their appearance under the XVIIIth Dynasty, and were so largely developed in Roman times, must form the subject of a separate study.

DISCUSSION.

THE CHAIRMAN, in opening the discussion, observed that he had never heard a theory so thoroughly revolutionary as that put forward by Mr. Burton presented in a calmer or more convincing way. It was, perhaps, less than justice to call it revolutionary, for it was difficult to say what would be the precise effect of Mr. Burton's discovery—for such it was—upon the technology of the ancient Egyptians. He (the speaker) thought scant justice had been done by Mr. Burton to the primitive races who had not already arrived at the refinement of adding glazes to their wares. He could show Mr. Burton, at the British Museum, a certain number of examples of unglazed wares which would command that gentleman's respect. Some of these were ancient British, some were from Spain, and of the Bronze Age; others were from ancient Mexico. All these had artistic qualities of shape and surface, and, as a potter of taste and experience, would command Mr. Burton's admiration. Mr. Burton

Hosted by Google

had indicated the difficulties confronting his theory, and had recited the well-known fact that the ancient Egyptians were in the habit of glazing stone. A point which Mr. Burton had not, to the speaker's mind, enlarged upon sufficiently was that, up to now, no one had been able to discover, according to any method known to potters to-day, how these so-called pottery figures and vessels could have been made. It was an astonishing thing that, being familiar with these things, Mr. Burton, and others dealing with archæological subjects, had not long ago gone a little further by analogy. The speaker, having realised the astounding nature of Mr. Burton's theory, had gathered a certain number of fragments of various dynasties—the XXIst and XXVIth, etc.—and had broken little bits up and put them under the microscope. He had found one piece of the XXIst Dynasty to correspond precisely with that which had been shown by Mr. Burton in the first slide exhibited. He had then got two or three pieces of mediæval Persian ware made in a way that had always been somewhat of a mystery. These pieces possessed this quality, that the glaze appeared to be the strongest part of the fabric, while the interior or body seemed to be nothing but sand. One of the fragments, a very beautiful specimen of about the thirteenth century, was placed under the microscope. In common with some of the pieces that had been shown on the screen, it had a dark turquoise glaze. Further, it had precisely the same features as were presented by the pottery of the XXIInd Dynasty, of which Mr. Burton had spoken. By the aid of the microscope, without polarised light, the quality of the body was identical with the ushabti figure of the XXIst Egyptian Dynasty, resembling the broken surface of a sugar-loaf. The bowl was so thin that it was inconceivable that it could have been carved in the way Mr. Burton had put forward as the process by which the ancient Egyptian figures were made. He would not attempt to explain the significance of that, nor would he pit his observation against the technical and chemical knowledge of Mr. Burton, but he would ask that gentleman to take an early opportunity of examining the piece himself. With regard to Mr. Burton's proof of his theory by dealing with a large quantity of material, the speaker was certain that every person interested in ceramics generally, or in Egyptian archæology, would be prepared to supply him with twenty times as much material as he could deal with. Mr. Burton's discovery would alter the technology sequence, so to speak, of Egypt, and he had pointed out, notably by the relations of the various objects to which he alluded, in what way that alteration would take place. The speaker disagreed with Mr. Burton's reference to enamelling on metal. He (Mr. Read) did not believe the practice existed in Egypt at all; at any rate he did not know of any examples. Inlaid glass or stones like *cloisonné* enamel were commonly found, but these were cut out cold and inlaid in divisions, whereas the essence of enamelling was that it should be fused in place. Mr. Read agreed with the lecturer as to the definition of porcelain; the laxity with which that word was used was a matter of difficulty, not only with Englishmen, but foreigners. Porcelain was as definite a thing as, say, rock crystal; yet people described as porcelain substances which, as Mr. Burton had shown, were sandstone. Such people would, however, regard as wild the description of a piece of rock crystal as glass, or the converse; yet the difference was not greater in one case than in the other.

Miss M. A. Murray pointed out that there were specimens of glass, such as Mr. Burton had spoken of, in the Ashmolean Museum at Oxford. There also were some glass beads, which were among the earliest specimens of their kind. She was not prepared to give an opinion on the revolutionary theory propounded by Mr. Burton, but, so far as she was aware, no vases or other objects of this glazed ware had been found which had fallen in the fire. None of these fallen pieces of glazed ware had been found in the Roman times in the kilns of Memphis. Whether that was an argument in favour of Mr. Burton's contention, she was not prepared to say. All the early glazed ware of which she had knowledge was small, with the exception of the great sceptre of blue glaze of the XVIIIth Dynasty, now in the South Kensington Museum, and standing something like five or six feet high. Glazed ware of the Roman times was, the speaker considered, pottery, as it had fallen in the fire. She would ask Mr. Burton whether he regarded the small glazed beads found in such numbers in Egypt as pottery or sandstone.

Professor J. M. Thomson, F.R.S., discussed the paper neither as potter nor Egyptologist, but as a chemist. Judging the author's theory from the standpoint of the analyses, it had strong support, as they certainly represented the composition of sandstone or some analogous mineral, not clay or pottery ware. There was also the strong evidence of the microscopic sections, which were perfectly distinct and different from pottery. From a chemical point of view, therefore, Mr. Burton had good reasons for his theory. The speaker's investigations related more to the colours in the glazes, and he was much interested in the author's remarks on them, especially about the early blue. He understood Mr. Burton to say the blue was copper. The greens, even the early greens, were known to be copper, and he was much interested in hearing of the approximate date of the early copper blue. He would ask the author if he knew the earliest date at which cobalt was found as a blue in such pieces. He would be glad also to learn whether, in any of the vessels microscopically examined by the author, there were three layers—the substratum, the siliceous matter, and the

Hosted by Google

glazes. He (the speaker) had had occasion to examine some Persian tiles for colours. He had noticed what appeared to be three different layers.

MR. NOEL HEATON said that, although he was something of an archæologist, he was not an archæologist of Egypt. He had, however, recently had the privilege of studying an adjacent civilisation in the island of Crete, which offered some points of support to Mr. Burton's theory. For himself he unreservedly accepted this theory. In this adjacent country of Crete most magnificent carvings in steatite were found. That was the next step. Many people would doubtless regard such carvings with wonder, and would dwell upon the difficulty of carving elaborate forms like these in natural stone. As Mr. Burton had pointed out, it was not necessarily always sandstone; other forms of schist and steatite were used. The country was in constant intercourse with Egypt at the time when these beautiful carvings were being made, not alone in steatite, but in harder stones. He did not know whether there were any actual examples of glazed steatite. A number of objects were also found which, without inquiry, had been taken to be glazed faience. He would like to suggest to the author that he should examine some of these. There were, at about the XVIIIth Dynasty a number of extraordinarily beautiful glazed objects, such as little statuettes of human figures, and it would be interesting to see if these turned out not to be pottery at all. The speaker had seen a lump of blue frit, from which the glaze was prepared; it was a mass cut out in the form of a vase. He did not consider any chemist, or anyone familiar with the fundamental technology of pottery, would deny that a substance containing 94 per cent. of silica and barely 2 per cent. of alumina could not be pottery. He could sympathise with the Chairman's difficulty in regard to the proper use of the term "porcelain." He had met similar trouble in the use of such words even as "fresco" and "glaze," and he had had some correspondence with the author on the use of the word "glaze" in connection with Attic pottery. Mr. Burton called it a "bituminous material." It was the same the world over; the builder and the geologist were in disagreement about the word "marble," for instance. With regard to enamelling, he had examined collections from time to time, but could not remember having seen anything which could be described as enamelled metal, and he did not quite see how, at such an early period, enamelled metal would have been possible, considering the nature of the glaze used.

MR. WALTER C. HANCOCK said that Mr. Burton's theory furnished an excellent example of the way in which the obvious was missed for centuries together. The analyses the author had shown were plainly of sandstone. Doubtless Mr. Burton was aware of the work of Professor Henri Le Chatelier, carried out five or six years ago, on certain so-called Egyptian pieces. The results of this work were identical with the analyses shown by the author. From the purely ceramic point of view, these pieces were not pottery. There was no doubt that the proportion of clay (if any) was infinitesimal, and would have absolutely no effect on the plastic properties of the mass. He had been interested in Mr. Burton's references to the use of colloidal and mucilaginous substances, especially as the point had been frequently raised of late years. From the few experiments made, he did not think it materially increased the "working" properties of the mass. With regard to Mr. Burton's theory, he did not think any very poignant criticism had been brought against it. The author had shown conclusively the alteration which took place in the body due to firing—the formation of solid solutions. It might be said that if the examples were of carved sandstone or schistous material, they might not have been fired at a temperature sufficient to bring about the changes of the body which would have been brought about in the case of ordinary porcelain. In attempting to reconstruct the technological processes of ancient times a great deal of evidence was derived from the surroundings in which the various articles were found—kilns and so forth—and it was of interest to know whether any tools which were at all likely to have been used in carving the schistose or quartzite materials had ever been found in conjunction with the carved materials. In conclusion, he had no doubt of the correctness of Mr. Burton's theory from a chemical point of view.

MR. E. E. PITHER inquired whether any other colours than blue and green had been found in this ancient ware. He had secured some time ago a piece which had a red colour, and a sort of lustre.

[Mr. Burton here stated that many colours were used, and during the period of the Roman occupation there was a great deal of polychrome ware.]

MR. WILLIAM BURTON, in reply, said that his object in reading the paper was to present the results of his studies, and show the direction in which they had been leading him for some years past. He was much interested in the Chairman's reference to the specimen of Persian ware of the twelfth and thirteenth century. The technique of carving in stone and glazing with glazes analogous to the earliest Egyptian had never ceased, but had travelled from Persia into the centre of Asia, and so into India and China. The Chairman had in his possession a fragment from the centre of Asia, and there were hundreds of such fragments. With regard to the expression "enamelling on metal," he could only assume that he had carelessly copied the phrase from the writings of some Egyptologist; he realised perfectly well

Hosted by Google

that enamelling on metal was not done. His object was to refer to the first use of a substance that could be called "glaze," which he would suggest, arose incidentally from the fusion of some malachite with other substances. The Egyptians undoubtedly glazed with glazes of that type, consisting of nothing but silicates of the alkalis and lime, coloured with oxide of copper, and that technique went on for certainly 2000 years. Then followed the production of glass paste, but not made in such a way that it could be blown, as the Roman and Phœnician glass could be. The Egyptians did not appear to have blown glass until a late period. Their manufacture of glass vessels arose from their first making glass paste. What was revolutionary in his remarks was this, that people had always assumed that the glaze of pottery was a glass, and that therefore the discovery of glass must have preceded the discovery of the glazing of pottery. He believed that the Egyptian glaze was the first discovery, and that glass itself followed a considerable time afterwards. He was grateful to Miss Murray for her suggestion that glass made its appearance as early as the First Dynasty. He could only say that there were different understandings of what was glass. He had seen the glass bead of Mena, of the First Dynasty, and had suspended his judgment as to whether it was glass. Replying to Miss Murray, with reference to the great quantities of beads, he was not prepared to say that none of the beads were of pottery, but in his opinion the early beads were made out of the glazing stuff itself. Miss Murray was right in her conjecture that in Roman times the glazed ware was pottery, because the pieces had been found sunk out of shape in the kiln, which again supported the speaker's theory. In the early dynasties none of these pieces were found which had gone out of shape in the fire. One difficulty arose on which he was unprepared with a suggestion. When did the transition take place between the application of glazes to objects carved only in stone and to objects fashioned in pottery clay and coated with siliceous coating? He believed that it began as early as the XVIIIth Dynasty. In reply to Professor Thomson, he would say that he had found so many mistakes in analyses, especially old analyses, that he preferred to make his own. He was aware of Le Chatelier's analyses, and would accept them. The blunders made by some of the older analysts showed how careful it was necessary to be in using other people's work. Professor Thomson had pointed out that in some old Persian stone he had found three layers. That was the old Persian technique referred to in the paper, where the body was shaped in a kind of clay which was fairly siliceous, then coated with a thin coating of a clay mixture very rich in silica, the glaze finally coming on the top. In making enamels on metal, the enamel might not attack the metal, but might simply melt and remain there. The melting of any form of glaze or glass on a piece of clay would be equivalent to melting mixtures of silicates of low fusibility on other mixtures of silicates of higher fusibility, and interaction was bound to take place between them. He had been the first to point out that there must be a kind of buffer layer between the glaze proper and the body proper, the body becoming gradually more body and less glaze in one direction, and more glaze and less body in the other. It was difficult to make people understand that while a pottery glaze was a glass, it was one of very special character. In relation to colour, there was no doubt that all the blues and greens of the oldest glazes were derived from copper only. For nearly five thousand years copper had been used as the colouring element, before there was any trace of cobalt having been used. The colours could all be made out of the same mixture, it being wholly a question of the temperature of the state of aggregation of the silicates; that was to say, how far the firing was pushed. Take a certain piece of Persian or of old Egyptian blue fired up to 1000° C. At 100° hotter than originally fired, it of course became green, and the more it was fired the greener it became.

The Chairman, in moving a hearty vote of thanks to the author, said that the deduction from Mr. Burton's analyses could only be in one direction, namely, that the material analysed could not be pottery or plastic material at all. This was contrary to the belief of archæologists and Egyptologists, and it was, to use an Americanism, "up to them" to show how the material was made if not made in the way Mr. Burton had suggested. On the question of glass derived from glazes, as Mr. Burton had said, there was *glass* and *glass*, and the glass paste referred to by Miss Murray probably would not make a blown glass vessel at all. There was the glass paste used for inlaying in exactly the same way as stones were cut. A similar material was modelled round a clay core, and the core withdrawn, the result being a glass bottle. It was necessary to be careful, in speaking of glass, to know precisely what was understood by the term.

The vote of thanks was carried unanimously, and the meeting terminated.

SHIPPING AND NAVIGATION OF PORT OF ANTWERP.

Sir Cecil Hertslet's annual report on Antwerp always contains interesting matter from a commercial and shipping point of view, and one of the principal features in that for 1911 is the very large increase in the port returns, which is indicative of great prosperity in the trade of Belgium. Sir Cecil remarks that this is largely due to the popularity of the port, which continues to attract traffic, notwithstanding the great efforts made by its powerful

Hosted by Google

competitors to outstrip Antwerp in proffering advantages to the trade. At present the accommodation of the port is barely large enough for the immense volume of shipping frequenting it, and much delay has occurred in the completion of the new docks which have been in hand so long. The new entrance giving access to the existing basins is also urgently required, but unfortunately appears no nearer a commencement than it was last year.

During the whole of 1911 freights have been hardening, and at the time of writing the report the situation in the freight market was quite brilliant, the quotations being good for practically every part of the world, a feature very rarely observable elsewhere.

In respect of tonnage of vessels, the returns for 1910 constituted a record, but notwithstanding that, and a strike of seamen, the figures for 1911 displayed an increase of 5½ per cent. over those of the previous year. A predominating position is still happily maintained by British shipping, which in respect of tonnage was 48 per cent. of the total for all countries. Germany is of course Great Britain's chief competitor, and the two together dominate the port.

The inland navigation of Antwerp is of a peculiar character, being carried on for a great part in large barges which are either towed or self-propelling. The trade may be compared with the coasting trade of London, with, however, this important difference, that the latter consists of vessels plying between London and other ports in the United Kingdom, while the barge or inland traffic of Antwerp is more of an international character, coming and going by canals and navigable waterways from France and Germany, in addition to the inland traffic of the country proper.

The number of passengers carried on the Harwich-Antwerp service shows a falling-off for the year 1911 compared with that for 1910, when the Brussels Exhibition caused a special inflation of the returns.

THE FOREIGN TRADE OF ITALY IN 1910.

The recently issued report on the foreign trade of Italy for the year 1910 contains a good deal of information of interest to British commerce. The total value of the trade is the highest recorded since the establishment of Italian unity, the value of the exports having increased as much as 11 per cent., while the imports show an increase of 4 per cent., the latter being mainly attributable to the higher price in 1910 of raw cotton (imported chiefly from the United States and British India), as well as to a larger importation of cereals (from Russia and Roumania), and of indiarubber (from Brazil). In the matter of exports, Italy has made remarkable progress, an increase of about £3,000,000 being recorded under the heads of spirits, wines, and oils, and of over £1,400,000 in cotton goods. With the exception of the silk trade, there has been a rapid recovery in Italy from the world-wide depression of 1908. Notwithstanding the steady increase in the use of hydro-electric power, there has been no falling-off in the importation of coal, a circumstance tending to show that Italian factories are doing well.

The vintage for the year was very poor, the worst since 1905, and this caused a sharp rise in prices of wine, especially on the receipt of increased orders from abroad. Switzerland is Italy's best customer, but a good deal of wine is also sent to Brazil and the United States, and endeavours are being made to obtain a steady footing in the Austro-Hungarian market.

The oil crop was double that of the preceding year, and exports to the United Kingdom exceeded by nearly one-half those of 1909, though the United States, the Argentine Republic, and France are Italy's best customers. Under the class of hemp, flax, and jute, there was considerable increase in exports, and in respect of raw hemp and thread the United Kingdom figures conspicuously.

The year 1910 was a disastrous one for the important cotton industry. Two successive short crops in 1908 and 1909 had brought about a heavy rise in the price of the raw article, so that many factories had to reduce their establishments or shut down altogether. Imports of raw wool increased largely during 1910, while those of the finished articles continued to decrease. Italian manufacturers are trying to drive foreign woollen goods out of the home market, but purchasers who wish to have goods of the best quality still insist upon British or German woollen cloth, in spite of the higher price of the former. Silk, raw and manufactured, the most important among Italian industries, had during 1909 shown signs of recovery from the serious crisis of the two preceding years, but in 1910 exports fell back once more, the total value of all kinds showing a decrease of £1,314,692, as compared with those of the preceding year.

While the importation of boots and shoes has nearly trebled during the last three years, exports have fallen to about one-third of the figures for 1908, Italian factories, which for the most part make use of handwork, being no longer able to compete with foreign machine-made goods.

The output of the Italian iron mines, chiefly situated in the Island of Elba, amounted in 1910 to 551,259 tons, being an increase of 46,064 tons over the figures for the preceding year. The production of pig-iron amounted to 353,239 tons, as against 207,800 tons in 1909, all being consumed in the country, in addition to 205,975 tons imported from the United Kingdom and Hungary. The low price of steel in Italy has fostered the manufacture of rails, of which up to 1907 Italy had to import large consignments. Local production has now almost doubled, and imports have decreased in proportion, Belgium, Germany, the United States,

Hosted by Google

and Great Britain, being the chief supplying countries in the order named.

In motor-cars there was a slight decrease, both in exports and imports. Italy's best customer is the United Kingdom, which during 1910 purchased no less than 813 cars out of a total of 2,120 exported.

Comparing the values of the trade with different countries, it is noteworthy that Germany still maintains the first place, both on the lists of imports and exports. As to the latter category, the United Kingdom has made great progress, and now ranks fifth among Italy's customers, the chief items showing increases being silk tissues, eggs, fruit and preserves, raw hemp, olive oil, etc. In regard to imports the United Kingdom is second in rank, but the values show a decrease as compared with 1909, owing to the fall in price of coal. There was a small increase in woollen stuffs, and in rubber goods the United Kingdom has made notable progress from £98,450 to £410,963. England has also more than doubled her exports of copper, brass and bronze wares to Italy, and is competing keenly with Germany in the supply of tools for working wood and metals.

THE MAHOGANY INDUSTRY OF HONDURAS.

One of the great sources of future wealth in Honduras will be found in the forests where mahogany grows, as there are thousands of acres where the timber is to be found in its primitive isolation. The fact that the mahogany forest, or even the mahogany grove, is non-existent makes for the high value of the wood. True, mahogany is the familiar dark coloured hard wood largely used for household furniture, supplied by a tree native in Mexico, Central America, Panama, Colombia, Venezuela and the Caribbean Sea. The tree sometimes grows to a height of one hundred feet, with a diameter measurement of twelve feet, Frequently trees are found that five men joining hands cannot circle. A decoction made from the bark was considered a remedy for fever, while the Aztecs used the seeds as one of the ingredients of a cosmetic. Its period of growth covers, perhaps, two hundred years, which fact, in connection with the limited area where mahogany is found, makes difficult the compilation of accurate data descriptive of the botanical history of the tree. According to a recent report by the International Union of American Republics, the principal false mahoganies are African or Senegal (the true tree grows in Nigeria), Australian (a eucalyptus), Ceylon mahogany, Indian (the toona tree in Bengal), Madeira mahogany (*Persea indica*, or canary wood), bastard mahogany, and in the United States, California and mountain mahogany. Nearly all real mahogany grows north of the equator in an area limited by the parallels 11° and 23° north latitude. Small areas in Panama, and recent sources of supply discovered in Africa, lie without this zone, but few trees of this species have as yet been found below the equator, which is curious in view of the fact that suitable climatic conditions exist in countries lying in corresponding latitudes south of the equatorial line. Logging for mahogany is carried on to-day in the same primitive manner that served in collecting the wood in early days. In the main it is the process used in the forests of the United States and Canada, with minor modifications because of special climatic conditions. Fortunately the trees are found near the coast. The trees are cut in the rainy season. A man climbs to the highest limbs that will afford him the best view of the forest. He marks down the mahogany by its conspicuous yellow-reddish leaves, then descends and leads the cutters through the jungle, hacking a road as they go, till the mahogany tree is found. Then saws and axes are applied, always at the time of the waning moon. The superstition that calls for the cutting of the trunk by the light of the waning moon is based on good botanical grounds, for experience has shown that the mahogany tree is freer from sap, sounder, and of a richer colour at that period. And the cool of the night offers the best time for the hard work, so the wisdom of the custom is apparent. The hauling of the fallen trunk to a stream is the work of oxen still, and must be done in the dry season when the ground is hard. Once in the stream, a raft is made, and floating is carried on just as in any logging country. At the ship's side the logs are immediately hoisted aboard to avoid the ravages of the boring toredo. London is the great mahogany market. It is well known that the wood is noted for its hardness, durability, beautiful colour and grain, and in the diversity of these qualities lies the value of the hewn trunk. There are two main differences in grain pattern, the close-grained mahogany, the best of which comes from Cuba and Jamaica, and the wide-grained, also known as baywood, the mahogany of Honduras.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

The Half-Time Question.—As Parliamentary debate of the half-time educational system has concerned itself with other points of view, it has necessarily left a few things unsaid which occur immediately to the textile manufacturer. Industrially, the affair is a textile one almost exclusively. Substantially, eight-ninths of the children of twelve to fourteen years of age who vary wage-earning with alternate half days of schooling do so in the heart of the textile region —*i.e.*, in Lancashire, Yorkshire, and Cheshire. No other industrial interest is affected in any comparable degree by the proposed overthrow of the arrangement. Cotton, worsted, flax, jute, and silk have each its cohort of half-timers, but these are not distributed equally over the industrial departments. The carded woollen trade has virtually none, and weaving and finishing find no

Hosted by Google

employment for them worth mention. The half-timers work in the spinning-mills chiefly at setting-on and taking-off bobbins, removing loose fluff from spinning rollers, and tying neat knots in broken threads. They are employed because the work is well within their compass, because of economy, and also because of ulterior technical advantage. Economy alone may explain the employment of the larger number; not necessarily that two half-timers are cheaper than one full-timer, but that a difficulty exists in ensuring a sufficiency of young, and consequently cheap, labour for the mills. The half-timer is broken in gradually to mill work and the manipulation of machinery, and, in some departments more than others, gains an advantage from an early start which lasts for the whole of her mill life. There are painters whose sincerity it is impossible to doubt who maintain that no artist attains the maximum of proficiency who does not begin serious practice before the age of fifteen. Similarly, there are worsted spinning managers who aver as stoutly that—be half-time bad or good educationally—it is an arrangement indispensable to the production of the finest yarns. The girl who begins at eight makes a better spinner for life than one who begins at nine, and every successive year of delay leaves its mark upon her aptitude. This proficiency is of less account in making the coarser yarns, and here the increasing automatism of machinery promises to relieve the demand for young labour. That the ability to produce ultra-fine botany yarns is jeopardised, there is, unfortunately, no doubt.

Although in Parliament the half-time question has been spoken of as though it chiefly affected boys, there are, in point of fact, considerably more girls, and to them the employment is anything but a "blind-alley." The experience gained in the spinning-room is advantageous, whether time leads her into the winding or weaving departments subsequently or not. In the case of boys it cannot be agreed by those who know the industry that ejectment from their posts in one mill leaves them in the unfavourable plight of those who have been following less disciplined callings. Difficulty in getting juvenile labour enough is said to have resulted in the employment of more married women in the mills of one district, and the probability that more mothers will go out to work because their children are prevented from doing so is a point which should not be overlooked.

Technical Instruction.—At an early date textile tuition was advocated in this country as one arm of the poor law. John Bellers propounded in 1696 the scheme which Pitt warmly commended a century later. In Bellers' "colledge of all useful trades" were to be "2 linnen and 2 woollen weavers, 2 flax-dressors and thred makers, 2 spinners and carders for stockins and 20 linnen and 20 woollen spinners and carders," whose permanent function was to have been the instruction of the young in these crafts. The college was never founded, and the first forerunner of the excellent textile colleges of this day was apparently the school of cotton-spinning opened in 1810 at the Conservatory of Arts and Trades in Paris. In 1843 a M. Lambelet opened a weaving school in Verviers, the chief centre of the Belgian woollen trade, and these seem to take priority over English efforts. Perhaps the records of the Mechanics' Institutes of the mid-nineteenth century contain reference to organised classes, and to such places and to tradition concerning early "mutual" classes one must look for information. The present colleges, equipped with machinery capable of carrying on all operations, began humbly as classes for the teaching of designing and cloth structure. It was thus with the textile department of the Yorkshire College, Leeds, which was founded in 1874. Until 1880 there was no department of dyeing, and until 1900 no spinning department. The textile equipment of the University has now been rounded off by the munificence of the Clothworkers' Company, to which Leeds is indebted for £75,000 worth of land, buildings and plant, and an endowment of £4,000 a year. The latest extension permits of instruction in systems of spinning which are little used in this country, although employed extensively abroad. The policy of introducing machines not found in the mills of the district has been followed also at Bradford, and textile teaching in most quarters devotes itself increasingly to research and exact examination of the results obtained by use of different means.

Foreign Students at Textile Schools.—Visitors to any of the large textile schools note amongst the day students a heavy proportion of foreign youths. English policy towards them is more liberal than the German, which charges fees three to six times higher to strangers than to natives. English fees are the same to all comers, and the fact is not one that textile machinists need regret. In his after career the student is drawn strongly to prefer the type of machine on which he learned his business. The machine is bought for the purpose of producing abroad something like English cloth, but this is not an undiluted misfortune. The user needs materials similar to the English as well as English machinery, and this disposes him towards the yarns and raw materials that English firms have to sell. Traders to the Scandinavian countries, for example, have positive evidence that the users of German machinery there incline always to use German materials upon them, and probably it is for these that the machines are best fitted. Where the machinery is English, the tide of favour is steadily in the other direction.

Fireproofing Cotton Goods.—Coroners' inquests continue to lend zest to the pursuit of efficient means of flame-proofing cotton goods. The conditions of the problem are against the chances of rendering it absolutely fireproof, as it is indispensable to retain the general characteristics which make cotton an eligible article of wear. The treatment must be cheap, for it is for application to the cheapest of fabrics, and the resultant need

Hosted by Google

not rival asbestos in indestructibility. It is necessary simply to render cotton as little inflammable as woollen or silk, in order amply to meet the requirement. Use of hygroscopic dressings is to be avoided, as pneumonia is as much an enemy as fire, and hygroscopic salts, being highly soluble, disappear promptly in washing. Irritant dressings are to be shunned, and this disqualifies for use zinc salts of recognised virtue against fire. Borax, common salt, alum, silicate of soda, sulphates and phosphates of sodium and ammonium and titanium salts are all recognised to have greater or less efficiency, and have all been used for the purpose. Tungstate of soda, made by fusing wolfram with soda ash, is the standard chemical for the purpose, and experimenters do not find the stannate of soda named in Dr. Perkin's patent to be an improvement on the cheaper salt. Flannelette treated with stannate of soda and ammonium sulphate has a large sale, and appears to retain much of its resistance after washing.

The World's Wool.—An Australian official estimate gives some 500 millions as the proximate number of the world's sheep. Some 600 millions are estimated by the United States census authorities, and not less than 700 millions is the total ventured by the statistician to a wealthy body of American manufacturers. The discrepancy is sufficiently glaring, considering that the figures relate to almost the same period. It is not, however, inconsistent with a remarkable unanimity as to the produce of wool. Despite the aberration of 200 million head, the authorities agree on an estimate of roughly 3,000 million lbs. of raw wool. The same total is suggested by the President of the French Customs Values Commission, and its probability is further supported by those received authorities, Messrs. Helmuth, Schwartze & Co., London, whose estimate of the raw wool produced in and imported into Europe and North America is 2,567 million lbs. This leaves some 400 millions to local consumers outside the chief manufacturing countries, and the item is not one about which it is necessary to trouble in practice. The volume may be accepted as real on the strength of the evidence, and, applying to it the mean value of 9*d.* per pound, a sum of £112½ millions remains as the probable value of the world's clip. Ninepence, it may be added, is the average value of the wool imported into this country in the decade 1900–09, and is below the price which has ruled since.

Messrs. Helmuth, Schwartze & Co. calculate that their 2,567 million pounds reduced to the clean state by washing shrinks to 1,412 millions, and for the present the supply per head of population is not decreasing. The population of the chief wool-consuming countries grows currently at the rate of six millions a year. In the period 1861–70 there was brought to the doors 2·26 lbs. of wool per head of the European and North American population, and on balance the amount has grown ever since, rising to 2·76 lbs. of clean wool in 1891–1900, but falling to 2·61 lbs. in the broken period 1901–06. Since 1907 the amount has increased 4 per cent., and is once more standing near the 2¾ lbs. limit. The allowance does not look excessive upon its face, and seems no more generous when regard is paid to the weight of one's personal clothing. A pair of blankets weighing eight pounds is not a heavy pair, and eighteen ounces the running yard is a normal weight for cloth to be used in suits. As a suit consumes 3¼ yards of cloth its weight may be taken at 3 lbs. 10 ozs.—or seriously more than a strictly equal division of wool would give, even were there no sinkage in manufacture.

NOTES ON BOOKS.

INDUSTRIAL EVOLUTION IN INDIA. By Alfred Chatterton. Published by *The Hindu* Office, Mount Road, Madras.

Those concerned with the passing wild anarchy in the fine and the applied arts of Europe, and who know Mr. Alfred Chatterton, whether personally or by his work in Madras, and how well equipped he is by his dispassionate natural temperament, and thorough scientific and professional training, and practical experience, to enter the lists in the controversy he so ably grapples with throughout this volume, will be the first, on opening it, to exclaim against its obtrusively defective titlepage. The book is made up of 369 crown octavo pages, of sound paper, carefully and clearly printed, and strongly bound together in glazed green cloth—with the matter of it all magisterial and of the widest interest—and yet its titlepage leaves the inquirer puzzled as to where to write for a copy of it. *The Hindu* is an Indian daily and weekly newspaper, having an office of issue in Mount Road, Madras; but it is printed by the Guardian Press, Blacker's Lane, and published by the National Press, Wallajah Road, while its address is "Post Box 82," Madras. This sort of carelessness is what makes it so difficult, even for persons like myself, to obtain books, published by native firms, direct from India, and almost impossible to do so through booksellers in England, who have repeatedly to reply to your applications, "address insufficient." The agent, or agents, for sale in England, should be named on the titlepage of every book produced in India, if meant for circulation in Europe and the Americas. Moreover, nothing of Mr. Alfred Chatterton's credentials are given on the titlepage; and he was not only Professor of Engineering under the University of Madras, and a Fellow of the University, and Member of its Faculty of Engineering, but had graduated before he went out to Madras as a B.Sc.

The outstanding note of the volume is the distinction drawn throughout it between the mechanical and the artistic industries of India, a distinction ever to be scrupulously and strenuously observed by all responsible for the welfare, alike moral and material, of the peoples of India, and

Hosted by Google

especially of the Hindus. In the simple mechanical industries, the Hindus, like most of the Caucasian races of Asia, are notably deficient; and there is indefinite room for the development of them; and an urgent necessity for it in a country where the rapid growth of the populations, under the British Raj, is beginning to press so alarmingly on the means of their support. But in the artistic industries, regarded, not as an economic asset, but as a spiritual dower and glory, India stands at the head of the Aryan world of Asia and Europe, and the Americas; and we cannot interfere between them in any way, and certainly not through our Schools of Art, unless it be the more considerately to protect them in their traditional idiosyncrasies, without doing serious, nay, deadly detriment not only to the hereditary craftsmen of the country, but to the artistic genius, and the religious faith and character, of the whole sacrosanct races and nationalities of Brahmanical Hindus. It was not always so with Mr. Alfred Chatterton. Going out straight from England to Madras, he at once set about valorously manufacturing, on behalf of the Government of Madras, goblets [*lotas*], bowls and basins, all of aluminium [clay feigning to be silver], in substitution of goblets, bowls, and basins of clay, and brass and copper, etc.; in ignorance of the fact that not only the uses, and the forms, and the decorations, but the very materials of these vessels, as used by Hindus, were all sacramental. This is our stubborn British way; and the pity of it is that the ruck of us in India persist in it—and in every branch of our administration—to the very end of our several individual lives; and every single Englishman, Scotsman, and Irishman is in India a potent influence for good—or for evil. But Mr. Alfred Chatterton soon saw his error, and in his case no great harm came of it; while now, by the publication of this book, and in the Presidency town of Madras, great good will be done, and not only in Madras, but in every part of India where the questions he so admirably discusses in it are daily engaging an ever increasing attention.

Mr. Alfred Chatterton divides the book into twelve chapters; and in the first, second, and third, treats of the Indian Industrial Problem generally, including the question of "Protection" and "Tariff Reform" for India; in the fourth, of Agriculture; in the fifth and sixth, of Industrial Enterprises generally, and Expert Assistance in the same; in the seventh, of Chrome Tanning; in the eighth, of Hand-loom Weaving; in the ninth, of Miscellaneous Industries, such as Wood Distillation and Milk Products; in the tenth, of Well Irrigation; in the eleventh, of Engineering in India; while in the twelfth, and final, chapter, he reviews the attitude of the Government in relation to the Industrial Evolution of India. From first to last the volume never fails in interest; and every chapter opens up the prospect of unlimited employment during the next hundred years and more in these new scientific industries for the natives of India, or failing them, through their want of ambition and energy, for Europeans. The evolution is, so to say, self-developing, and must not be hustled and rushed, but be simply, and sedulously, and sympathetically, watched, and eased, and supported in its course, and with the divine long suffering of Nature that

"... from the mire,
In patient length of days,"

has elaborated the glory and the wonder in the highest of the whole Cosmos. Above all, we must never forget that the people of India still, in spite of all our European education, happily believe in the unknown powers of the universe. Some forty years ago, the wells having failed over a wide district in Gujerat, the ryots refused to pay the half-yearly assessment on their lands. Their refusal was so prolonged, and at last became so menacing, that the Government of Bombay were on the point of sending up a detachment of European troops to enforce payment; when Sir Barrow Ellis, an Israelite indeed, in whom there was no guile, shocked by the proposal, said: "There's George Pedder, he knows these people well. Send him up, as a last resource, and see what he can do with them." Pedder was sent, and asking the assembled ryots why they had not paid up, they at once replied: "A devil is in possession of the wells, and it is for him to pay." "Right," said Pedder, "I'll issue the Sircar's summons to the devil to pay." "Yes," they replied, "and lay it down here, and we will all come again to-morrow morning, and you will find the money on the summons." "But," said Pedder, "suppose I don't." "Oh, then," they at once exclaimed, "it will be plain the devil is not in possession of the wells, and we will of course pay." They paid, and rejoicingly, and there and then at once made ready a bountiful breakfast for Pedder, of fresh baked *chupatis* [griddled pat-a-cakes], and fresh drawn milk, and fresh gathered fruits; and to this day you will, I venture to say, find George Pedder's name of great praise in their mouths, and of their children. *That* is their Indian way, and assuredly it is the wiser way, if but for its peacefulness and pleasancy.

GEORGE BIRDWOOD.

THE WEAVING INDUSTRY OF EGYPT.

With reference to the article on the above subject, which appeared in the *Journal* of February 16th last, it should have been mentioned that the facts were derived from a pamphlet entitled "L'Industrie du Tissage en Égypte," by Mr. Sidney H. Wells, Director-General of Agricultural, Technical and Commercial Education in Egypt (Le Caire: Imprimerie de l'Institut Français d'Archéologie Orientale). The pamphlet contains a great deal of valuable information, and deserves the careful attention of all interested in the subject.

GENERAL NOTES.

Exhibition of Articles and Appliances used for Packing.—The Orleans Railway Company are organising an exhibition of articles, materials and appliances used for the packing and conveyance of goods of every description, but more particularly with regard to poultry, meat, fish, fruit, vegetables, butter, eggs, etc. The exhibition will be held simultaneously with the four great agricultural meetings this year, at Bourges, Libourne, Limoges and Poitiers. Prizes will be given for the best plans for packing household provisions. The methods used for packing must be simple, practical and economical. As each exhibit must bear the name and address of the maker, an excellent opportunity for advertising their goods will be thus afforded to exhibitors.

The World's Petroleum Production.—The world's output of crude petroleum in 1910 was 327,472,256 barrels of forty-two gallons each, against 298,326,073 barrels in 1909. Of this amount the United States alone produced 209 million barrels, Russia 70 millions, Galicia 13 millions, Dutch East Indies 11 millions, Roumania 10 millions, and India 6 million gallons. The Canadian production has been decreasing steadily since 1907, while the imports into that country have been on the increase. Production of oil did not increase greatly in Mexico during 1910, but the results of explorations in that year made large supplies certain, and gave to Mexico the competitive position towards the United States that has long been imminent. Mexico's production of crude petroleum rose from one million barrels in 1907 to over three millions in 1910, while the Mexican imports of crude and refined petroleum from the United States increased from 19 million gallons in 1908 to 48 millions in 1910. In spite of continued unfavourable conditions, the production of crude oil in Russia during 1910 increased four million barrels over the preceding year. This was due to the increased production of the Grosny, Surakhany, and other new fields. The Baku district, which contributed the greater part of the product, remained almost stationary. In Galicia the production declined for the first time for years, on account of low prices for crude and refined oil, due to sharp competition for a market insufficient for the supply.

The Population of the World.—The population of the world, according to Herr Gulischambarof, a Viennese *savant*, is estimated at upwards of 1,700 millions. With regard to sex, data are only available for 1,038 million of this number, or 521,700,000 males and 516,300,000 females, being in the proportion of 990 females to 1,000 males. In Europe and Africa the number of females is greater than that of the males, being in the proportion of 1,045 females in Africa and 1,027 in Europe to 1,000 males. In the other parts of the world the females are less numerous, being 964 in America, 961 in Asia, and 937 in Australia per 1,000 of the opposite sex. In certain districts in Africa, however, the proportion of females to that of the males is even greater, for instance in Uganda, where there are 1,467 women to 1,000 men. On the other hand, in the western States of North America, British Columbia, and east Australia, the number of males far exceeds that of the females, as for instance in Alaska, where there are only 391 females to 1,000 males, and in the Malay States, where the proportion is 389 to 1,000 only.

Failure of Chinese Human Hair Supplies.—Experts in the human hair trade in Hong-Kong are calling attention to the fact that the disposition of buyers of human hair in Europe and the United States to expect a great over-supply of the material as a result of social and other changes, including queue-cutting, in China, is likely to lead to disappointment. Instead of an over-supply, the changes now going on are cutting off the chief sources of supply in China, and there is likely soon to be a decided falling away. The situation hangs upon the disposal of the queues of Chinese men. Contrary to the general impression in Europe and America, the queues when cut are not sold. This is an absolute rule, so far as south China is concerned, and the American Consul-General at Hong-Kong says that it is the custom all over those parts of China from which he has been able to secure reliable data on the subject. The queues when cut are preserved, according to general statement, for burial with the owner. The chief supply has come from Chinese barbers' shops where, in the course of shaving portions of the heads of customers, a good deal of long hair is accidentally removed. Now that queues are cut, however, Chinese barbers have no more long hair to dispose of than barbers in Europe and America.

Bolivian Rubber.—Next to tin, the most important product of Bolivia is rubber, the annual export value of which is estimated at a million sterling. The exploitation of the rubber lands is regulated by law through an annual export tax. The principal areas lie in the north-east, near the Peruvian boundary; in the east, in the province of Santa Cruz; and in the Acre and Beni territory, which is exceptionally rich in its yield. The Acre territory is watered by several large rivers originating in the Cordillera and flowing into the Amazon. These are the Beni, Madre de Dios, the Orton and the Acre. Two varieties of rubber plant are found; the "caucho," which has to be cut down in order to extract the sap, and the "hevea," which is merely tapped. In some cases the trees are tapped for a period of two years, and are then left for a similar period. Other rubber trees are tapped for six years at a time, and then left untouched for a like period. The trees selected for tapping are usually from thirty to forty years of age, and are expected to yield for twenty years, after which they become useless.

The Bronze Powder Industry of Germany.—Nuremberg is the centre of the bronze powder industry of Germany. With the exception of one factory at Munich, and one at Frankfort-on-the-Main, all bronze powder factories of any magnitude are found in Nuremberg and Fuerth, and the smaller towns in the vicinity. The raw materials used in the manufacture of the better kind of bronze powder are copper and zinc. For cheaper kinds, various descriptions of metal scraps from the toy and other factories are mixed with these two basic metals. The metals, mixed in graphite crucibles, are placed in furnaces, where they are reduced to a molten mass in about five hours and then poured into moulds and cast into half-round ingots about twelve inches in length and about five-eighths of an inch in thickness. The ingots are flattened under water-power hammers, and passed through rollers under great pressure until they are extended into metal ribbons many yards in length. Before becoming so brittle as to break, these ribbons are annealed in a furnace which is fired only with wood. They are then cut into strips about two yards long, tied into bundles of approximately 100 each, and hammered out still thinner. After being subjected to another annealing process two or three of such bundles are tied together and again hammered. At this stage the thin metal sheets are put through a cleaning process, tied into still larger bundles, and again beaten out under the hammer. When the required thinness is secured, the sheets are cut and torn into shreds and placed in hermetically closed iron boxes, in which they are pounded into a powder under vertical iron stamps. They are passed from one stamp-mill to another until reduced to the fine metallic flour known as bronze powder.

The Fisheries of Eastern Siberia.—Fish are caught in eastern Siberia by means of weirs and nets. The weirs are of two varieties, the "giliak," or native type, and the Japanese type, known as the "ta-te-ami." Both types are similar in construction. According to the American Consul at Vladivostok, the "giliak" type consists of a fence of willow poles and branches built from the river bank or from a sand-bank. The fence is built out as far as the fairway, and turns at right angles down stream. At the end of the second section of the fence, a net is set by means of ropes so placed as to indicate the presence of fish in the net, and the net is closed when twenty to thirty fish have been caught. The fish are then placed in a boat, and the net re-set. During this operation two men are employed. In the Japanese type the net arrangement is more productive, as in place of a bag-net a draw-net is used in connection with a fish-pond made of net or wire. When a sufficient number of fish are in the net they are driven into the pond, where they are kept alive until they are taken into the boats. This type of trap catches many thousands of fish per day. From ten to thirty men are employed, depending upon the size of the net.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

May 8.—E. D. Morel, "British Rule in Nigeria." Sir Edouard Percy C. Girouard, R.E., K.C.M.G., D.S.O., late Governor of Northern Nigeria (1908–9), and of the East African Protectorate (1909–12), will preside.

May 15. — Ernest Kilburn Scott, Assoc. M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere." Sir William Ramsay, K.C.B., Nobel Laureate, F.R.S., will preside.

May 22. — Gordon Craig, "Art of the Theatre." Miss Ellen Terry will preside.

Indian Section.

Thursday afternoon, at 4.30 o'clock:—

May 16.—Neville Priestley, Managing Director, South Indian Railway, "Indian Railways."

Colonial Section.

Tuesday afternoons, at 4.30 o'clock:—

May 7.—Alan Burgoyne, M.P., "Colonial Vine Culture." The Right Hon. Sir Walter Hely-Hutchinson, G.C.M.G., late Governor of Cape Colony, will preside.

May 21.—The Hon. J. G. Jenkins, "Australian Railways."

Howard Lectures.

Monday evenings, at 8 o'clock:—

Captain H. Riall Sankey, R.E. (retired), M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

Syllabus.

Lecture II.—May 6.—Various types of Diesel engines—Considerations affecting design—Design of various parts, such as cylinders, valves, pistons, connecting rods, crank shafts, frames, air compressors, etc., for 4-cycle and for 2-cycle engines—Materials used for the various parts—Number and arrangement of cylinders for vertical and horizontal engines.

Lecture III.—May 13.—Description of Diesel engines manufactured by various makers—Sizes in current manufacture and future possibilities—Speeds and weight for land and marine engines—Various kinds of oil available for Diesel engines; their characteristics, calorific value, and sources of supply.

Lecture IV.—May 20.—Economical results in respect of fuel and of total annual cost—Comparison of Diesel, gas and steam engines, in respect of capital cost, fuel cost, and total annual cost—Various applications to land and marine purposes—Other heavy oil engines—Semi-Diesel engines.

Hosted by Google

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 6...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Howard Lecture.) Captain H. R. Sankey, "Heavy Oil Engines." (Lecture II.)

Farmers' Club, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mr. A. E. Humphries, "Home-Grown Wheat."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 7.30 p.m. Mr. W. Yorath Lewis, "The Effect of Intermittency in Limiting Electric Traction for City and Suburban Passenger Transport."

Chemical Industry (London Section), Burlington House, W., 8 p.m. 1. Mr. R. Lessing, "A New Apparatus for the Coking Tests of Coal." 2. Mr. H. E. Williams, "A New Method for the Determination of Ferrocyanides." 3. Mr. J. H. Coste, "A Drying Oven." 4. Messrs. E. W. Lewis and H. Waumsley, "Indiarubber as a Protective Colloid."

Surveyors, 12, Great George-street, S.W., 7 p.m. (Junior Meeting.) Mr. J. Bunny, "Principles of Silviculture."

Geographical, Burlington-gardens, W., 8.30 p.m. Mr. C. L. Temple, "United Nigeria."

Victoria Institute, 1, Robert-street, Adelphi, W.C., 4.30 p.m. Mr. M. N. Tod, "International Arbitration in the Greek World."

TUESDAY, MAY 7...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Mr. Alan Burgoyne, M.P., "Colonial Vine Culture."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. F. B. Browne, "Insect Distribution, with special reference to the British Islands." (Lecture II.)

Alpine Club, 23, Savile-row, W., 8.30 p.m. Mr. E. A. Broome, "The Nord End from Macugnaga."

Literature, Royal Society of, Caxton Hall, Westminster, S.W., 3 p.m. (Browning Centenary.) 1. Sir Arthur Pinero, "Browning as a Dramatist." 2. Mr. Henry James, "The Novel in the Ring and the Book."

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. W. Bickerton, "The Practical Side of Bird Photography, and its Value in the Study of Natural History."

Zoological, Regent's Park, N.W., 8.30 p.m. 1. Dr. Francis Ward, "Lantern and Kinematograph Demonstrations of Photographs of Fishes and Aquatic Animals in Natural Illumination." 2. Mr. G. A. Boulenger, "On a Collection of Fishes made by Mr. A. Blayney Percival in British East Africa to the East of Lake Baringo." 3. Mr. Rowland E. Turner, "Studies in the Fossorial Wasps of the Family Scoliidæ, Sub-families Elidinæ and Anthoboscinæ." 4. Mr. Abel Chapman, "Notes on the Spanish Ibex."

Colonial Institute, Whitehall Rooms, Whitehall-place, S.W., 4 p.m. Mrs. Henshaw, "Mountain Trails in the Rockies of Canada."

WEDNESDAY, MAY 8...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. E. D. Morel, "British Rule in Nigeria."

Biblical Archæology, 37, Great Russell-street, W.C. 4.30 p.m.

Automobile Engineers, at the Institution of Mechanical Engineers, Storey's-gate, S.W., 8 p.m. Mr. R. G. L. Markham, "Internal Combustion Engines for Marine Work."

Literature, Royal Society of, 20, Hanover-square, W., 5.15 p.m. Professor Henry Newbolt, "Poetry and Personality."

THURSDAY, MAY 9...Automobile Engineers, 13, Queen Anne's-gate, S.W., 8 p.m. (Graduate Section.) Mr. H. Burchall, "Tyres."

Royal, Burlington House, W., 4.30 p.m.

Antiquaries, Burlington House, W., 8.30 p.m.

Child Study Society, at the University of London, South Kensington, S.W., 7.30 p.m. Annual Conference. Presidential Address by Sir James Crichton Browne.

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 4.30 p.m. Annual General Meeting.

Royal Institution, Albemarle-street, W., 3 p.m. Professor J. Norman Collie, "Recent Explorations in the Canadian Rocky Mountains." (Lecture II.)

Electrical Engineers, Victoria-embankment, W.C., 7.30 p.m. Extraordinary General Meeting to consider New Articles of Association.
8 p.m. 1. Messrs. S. W. Melsom and H. Eastland, "The Behaviour of D.C. Watt-hour Meters more especially for Traction Loads." 2. Professor D. Roberston, "Electric Meters on Variable Loads."

Mathematical, 22, Albemarle-street, W., 5.30 p.m.

FRIDAY, MAY 10...British Science Guild, at the Chemical Society, Burlington House, W., 8.30 p.m. Mr. A. E. Martin, "Coal."

Royal Institution, Albemarle-street, W., 9 p.m. Professor W. Stirling, "The Gaumont Speaking Kinematograph Films."

Malacological, Burlington House, W., 8 p.m. 1. Mr. Harold Hannibal, "A Synopsis of the Recent and Tertiary Freshwater Mollusca of the Californian Province." 2. Mr. A. J. Jukes-Browne, "*Dosinia lucinalis* Lam. and its Synonyms." 3. Mr. Tom Iredale, "New Generic Names and New Species of Marine Mollusca."

Astronomical, Burlington House, W., 5 p.m.

Metals, Institute of, at the Institution of Mechanical Engineers, Storey's-gate, Westminster, S.W. 8.30 p.m. Sir J. Alfred Ewing, "The Inner Structure of Simple Metals."

Engineers, Junior Institution of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 8 p.m. Mr. Alex. J. Gayes, "Notes on Telephone Exchange Equipment."

Physical, Imperial College of Science, South Kensington, S.W., 8 p.m.

Child Study Society, at the University of London, South Kensington, S.W., 10.30 a.m. Annual Conference. 1. Dr. J. Kerr Love, "Influence of Defects of Hearing in Relation to the Mental and Physical Development of the Child." 2. Mr. B. P. Jones, "Demonstration with ex-Scholars on what may be done for the Hard of Hearing by a Teacher of the Deaf." 3. Mr. N. B. Harman, "Influence of Defects of Vision in Relation to the Mental and Physical Development of the Child." 4. Dr. Jane Walker, "The Tuberculous Child."
8 p.m. Dr. C. W. Saleeby, "Eugenics and Child Study."

SATURDAY, MAY 11...Royal Institution, Albemarle-street, W., 3 p.m. Mr. H. Plunkett Greene, "Interpretation in Song. Lecture I.—Equipment."

Child Study Society, at the University of London, South Kensington, S.W., 10.30 a.m. Annual Conference (continued). 1. Dr. Theo. Hyslop, "Mental Hygiene in Relation to the Development of the Child." 2. Mr. J. Gray, "Demonstration on Appliance for Estimating Mental Aptitudes." 3. Dr. G. Eric Pritchard, "Instruction of the Young in Sexual Hygiene."

Meteorological, Temperance Institute, Southport, 8 p.m. Mr. W. Marriott, "A Chat about the Weather."

Municipal and County Engineers, Nuneaton, 11.30 a.m. (West Midland District Meeting.) Mr. F. C. Cook, "Ten Years' Municipal Work in Nuneaton.'

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,103. VOL. LX.

FRIDAY, MAY 10, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

NEXT WEEK.

MONDAY, MAY 13th, 8 p.m. (Howard Lecture.) CAPTAIN H. RIALL SANKEY, R.E. (retired), M.Inst.C.E., "Heavy Oil Engines." (Lecture III.)

WEDNESDAY, MAY 15th, 8 p.m. (Ordinary Meeting.) ERNEST KILBURN SCOTT, Assoc. M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere." SIR WILLIAM RAMSAY, K.C.B., Nobel Laureate, F.R.S., will preside.

THURSDAY, MAY 16th, 4.30 p.m. (Indian Section.) NEVILLE PRIESTLEY, Managing Director, South Indian Railway, "Indian Railways." THE RIGHT HON. SIR EDGAR SPEYER, Bart., will preside.

Further details of the Society's meetings will be found at the end of this number.

HOWARD LECTURE.

On Monday evening, May 6th, CAPTAIN H. RIALL SANKEY, R.E. (retired), M.Inst.C.E., delivered the second lecture of his course on "Heavy Oil Engines."

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Tuesday afternoon, May 7th; THE RIGHT HON. SIR WALTER HELY-HUTCHINSON, G.C.M.G., late Governor of Cape Colony, in the chair. A paper on "Colonial Vine Culture" was read by MR. ALAN H. BURGOYNE, M.P.

The paper and discussion will be published in a subsequent number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, April 25th, 1912; THE RIGHT HON. LORD MACDONNELL, G.C.S.I., K.C.V.O., in the chair.

THE CHAIRMAN, in introducing the lecturer, said Sir John Miller had recently been a member of the Government of India, and before that time was Chief Commissioner for the Central Provinces. There could be no better exponent of the charms and the interests of those Provinces than Sir John Miller.

The paper read was—

THE CENTRAL PROVINCES.

By SIR JOHN O. MILLER, K.C.S.I.

Ever since I accepted the invitation of the Society to read a paper on the Central Provinces, I have been conscious of being open to the charge of presumption in attempting to speak of a part of India with which my connection has been but brief. Many descriptions of Indian Provinces have been given here by members of the Indian Services, who had a long and distinguished career in the particular tract they dealt with. They brought, not only enthusiasm, but much local patriotism to their task; they spoke under that fascination which any and every part of India seems to exercise on the Englishman who has spent much of his life there; and they were able with sincere conviction to point to the pre-eminent claims which their own Province had to your interest and admiration.

I have not the same advantage, and in case I should fail to do justice to what has been called the "Cinderella of the Indian Provinces," it is right to explain that my acquaintance with the Central Provinces, though much longer than the proverbial six weeks which suffices for a book on India, is yet much too short for the intimate knowledge of a particular tract expected

Hosted by Google

by this Society in a paper. To a great extent I am an outside critic, and if in these circumstances an excuse is required for my appearing here, I would ask you to find it in this, that the Province has deeply interested me, that I should like, if possible, to convey some of that interest to you, and that no one out of the many persons who are far better qualified to do so has as yet made the attempt. If I can whet your interest to the extent of making you desire further information from some one who can speak with greater knowledge and authority, I shall be amply satisfied.

In speaking of the Central Provinces, except where the contrary is expressly stated, I mean the Central Provinces and Berar—the administrative unit under the Chief Commissioner. To the usual claims of Provincial pre-eminence these Provinces make no pretensions. They are amongst the poorest, they are the most retiring, and, except by the sportsman, the least known and the least regarded of the Provinces of India. They were also at one time the youngest, but it is hard to say what Province has now the best claim to that distinction. They have no great and renowned cities; they contain no archæological remains of world-wide fame, and no architectural monuments that attract the tourist; they have no frontier problems to keep them in the public eye, and even their natural beauties are almost inaccessible except to dwellers in tents. They have not a single newspaper of importance. The traveller, perforce, passes through them; if he goes to the north he may take a momentary interest in the frowning fortress of Asirgarh, guarding the entrance to the valley of the Nerbudda, or on the Calcutta route he may be charmed by glimpses of forest scenery; he may even make a brief stay at Jabalpur to see the Nerbudda swirling through the marble rocks, but unless he is bent on sport he hurries on, scarcely knowing what part of India he has been traversing. Nor do the Provinces lay themselves out to tempt to a prolonged stay; the lack of good hotels and of good communications tells its own tale of the general absence of interest in the secluded Province that occupies the centre of the country.

And yet it is extremely interesting, and no Province perhaps brings into such vivid juxtaposition the contrasts and diversities that characterise India as a whole. It is a microcosm of India, of India's history, and of India's problems. It is a common remark, for instance, that there is no Indian nation. Nowhere is the meaning of that remark brought out more clearly than in the Central Provinces, and the comparative absence of the Mohammedan element only serves to give point to the general proposition. A remark of the missionary geologist, Dr. Hislop, whose name is still preserved by the college he founded at Nagpur, is instructive and worth remembering. Speaking of that place, he showed how it was in a sense at the geological centre of the Peninsula. West of it lie the hills of trap that stretch to the Arabian Sea; east of it are the massive piles of granite that extend to the Bay of Bengal. "Walk round Sitabaldi," he said—Sitabaldi being a small hill in Nagpur, of which there is more to be said later—"and you may meet almost every rock that is to be found between Bombay and Calcutta." And the geological analogy may be extended to almost every aspect of the description of the Province. North and south, east and west, old and new, here meet and contrast themselves. Ethnologically the contrasts range from the up-to-date enterprise of the Parsi, whose influence here, as elsewhere, is out of all proportion to his numbers, and the keen and vigorous intellect of the Marathas, to the primitive simplicity of forest tribes who still arm themselves with bows and arrows. In religion there is always in India the contrast between the most elevated and spiritual forms of communion with the unknown and the lowest forms of fetish worship, but nowhere else is it forced so prominently on the attention. There are those who rigidly observe the strictest tenets of Brahmans and Jains, and there are forest tribes that do not abstain from feeding on lizards or mice or snails. In the north and east the common language is a dialect of the Hindi of northern India, in the west it is the Marathi of Bombay; while on the southern and eastern fringes there are people who speak only the Telugu of Madras, or the Uriya of Orissa. A few miles from a bustling railway station, where the merchants are struggling for precedence of their cargoes of cotton or rice, or oil-seeds or wheat, you may meet a caravan of Banjaras, still plying their old trade as the transport corps of India—the children sleeping on the backs of the pack animals, the sturdy men and stalwart women striding alongside, with an escort of dogs of different breeding and temper from the village pariah. In administration there are in operation both the great Indian systems of revenue settlement, the *ryotwari* of Bombay and Madras, and the *zamindari* of Hindustan; in excise the arrangements common in Upper India are being replaced by others borrowed from the

Hosted by Google

south, and similar contrasts might be indefinitely elaborated.

The Central Provinces lie on the northern border of the old Indian continent, not far from where it must once have been washed by the sea before the Himalayas arose and the great plains of Upper India were formed. One swarm of immigrants after another has swept down those fertile plains, bringing new and more vigorous civilisations with them, and spreading into the more accessible parts of the Province itself, while higher up in the hills and forests the life of the aboriginals in the jungles has been till lately hardly affected. It is with a feeling almost of regret that one turns from the freshness and simplicity of life in the forests to the hard facts of history and administration; but there need be the less reluctance to do so as the backward tracts of the Central Provinces have been fertile in literary inspiration. You may read of them in Forsyth's fascinating "Highlands of Central India," or in "Camp Life in the Satpuras," and does not Mowgli himself owe his birth to that country?

I would ask your attention for a moment to the physical geography of the tract. The great rivers of India flow generally east and west, and the watershed is, as a rule, far to the west. In the north, in the Himalayas, it is formed by the ridge on which Simla stands, and it is an interesting fact that the British Government should, merely by chance, have chosen the dividing line of the outer Himalayas for the seat of its summer capital. To the south the watershed is in the western ghats not far from the west coast, but between Hindustan and the Deccan a long trough, as it were, projects far into the heart of the Peninsula. The northern side of this trough is formed by the Vindhyas, the southern by the Satpuras.* North of the Vindhyas the drainage finds its way to the Jumna and the Ganges; south of the Satpuras, except in the extreme west, it is intercepted by the Godaveri or the Mahanadi, in all these cases flowing east into the Bay of Bengal. But between the two ranges the watershed is thrown far to the east in the tumbled mass of highlands, in which Satpuras and Vindhyas seem to meet and to lose their identity, away to the east of Jabalpur. There, just beyond the Provincial boundary, rises the holy hill of Amarkantak, over 3,000 ft. in height. On one side, below the old temples which Hindu devotion has raised in this picturesque plateau, is the series of pools that mark the earliest beginnings of the Nerbudda, while across the brow of the hill are the channels that carry the drainage east to the Son, and so to the Ganges and the Bay of Bengal. The priests from the temples suggest that the Nerbudda and Son do not exhaust the sanctity of the locality, and that close at hand is the source of another mighty but invisible river. They do not expect to be believed, but they are not far wrong, for the spot cannot be at any great distance from which the hill streams fall down the southern slopes of the range on their way to join the great river—the Mahanadi. Amarkantak is thus a place the central position of which, on the Indian continent, is worth remembering.

The map of the Province shows that it is entirely surrounded by Native States, except in three places. On the south-east it touches Madras; on the north it is conterminous for a very short distance with the United Provinces; and on the west there is a narrow strip of British territory, in the valley of the Tapti, where the Central Provinces meet Bombay. They are thus very nearly an island amid Native States, and they are formed of districts which either came under our rule at a comparatively late date, or which could not conveniently be administered by any of the earlier and greater Governments. As now constituted, they are composed of territories of which we undertook the administration at three distinct periods—territories differing in their history, their peoples, and their resources, with little indeed in common except that the harrow of the Marathas had passed impartially over them all. The tracts that came under British rule at these three periods are the following:—(1) The Satpura and Vindhyan plateaux (except two districts), and the Nerbudda valley between them; (2) the plains of Nagpur and Chattisgarh, and the districts above the ghats of Balaghat and Chindwara; (3) the country below the western Satpuras—Berar.

The first section was formerly a part of the Saugor and Nerbudda territories, which came under our rule after the war of 1817–18, and were administered before the Mutiny sometimes by a special Agent, sometimes by the Government at Allahabad. They now form two Commissioners' Divisions. The tract is a high-lying one. The lowest part of it—the valley of the Nerbudda—rises from 700 ft. in the west to 1,300 ft. at Jabalpur. On the Satpura plateau the station of Chindwara is at a height of 2,200 ft. above sea-level; while Pachmarhi, to

* The term "Satpuras" is used throughout in its local meaning to denote the hills and plateau south of the Nerbudda.

which the administration moves in the hot weather, is at a height of 3,500 ft.

On the north of the Nerbudda the station of Saugor—one of the most picturesque of British stations south of the Himalayas—is 2,000 ft. above the sea.

The second part of the Province, which also forms two Commissioners' Divisions, is usually referred to as the plains of Nagpur and Chattisgarh, but it is a country of rolling plains, diversified by hill and forest, entirely unlike the level plains of Upper India. The Nagpur country slopes generally to the south, Nagpur itself being 1,100 ft. above sea-level, and Chanda to the south, only 650 ft. It drains into the Godaveri. The general slope of the Chattisgarh plain is to the east, Sambalpur, just beyond its eastern boundary, being only 450 ft. above sea-level. The great river of these parts is the Mahanadi.

Such brief account of the history of the Province as time admits of can most conveniently be given with reference to this second section. Passing over the mass of legend and conjecture, and the particles of truth in the accounts of olden time, the supposed evidence of Scythian nomads in the stone circles and mounds which the antiquarian describes with reference to such familiar terms as barrows and cromlechs, passing over the connection with northern India in the journey of Rama through the forests peopled with strange monsters till he emerged at Ramtek near Nagpur, and passing over all the confused accounts of the dynasties of the Deccan, we may come at once to modern and comparatively authentic times. About 1600 the country was in the hands of a Gond dynasty, ruling first at Deogarh above the Ghats and then at Nagpur, the city of the Nag or hooded snake which protected the founder of the line, and it attained a degree of civilisation and power that we should hardly expect from the unaided efforts of the Gonds as we know them now. A century after, about 1700, towards the close of the long reign of Aurangzib, the Gond prince was a man of unusual ability. He attended the Imperial Court, and he adopted the Imperial religion, but he ruled his people well and wisely. He encouraged the settlement of Hindu cultivators and artisans, and raised his kingdom to a considerable pitch of prosperity, so much so, unfortunately for the Gonds, that on the weakening of the Imperial power it presented an attractive morsel to the rough but vigorous Maratha captains who were carving out kingdoms for themselves from the members of the decaying empire. Just as Holkar and Scindia established themselves in the north, so to the side of Gondwana came another Maratha family, that of the Bhonslas. Taking advantage of family feuds amongst the Gonds, and acting at first as Protectors under the shadow of the nominal suzerainty of the Gond king, they gradually consolidated their own power. The first members of the line were hardy warriors, simple in habits, but rapacious, accessible but ambitious, plain men, but more than able to hold their own in these days of turmoil. By 1800 they had extended their power over the whole of the Province, and, beyond its limits, over Orissa and part of Chota Nagpur. In 1803 they threw in their lot with Scindia against the British. They left him to be defeated at Assaye, but were a few weeks later attacked by Wellington and driven off the field of Argaum in North Berar. In the peace which followed they lost Orissa and Berar, and a Resident was attached to their court, the first being Mountstuart Elphinstone, who had in a civil capacity attended Wellington in the field during the war. Up to that time the Maratha chiefs seem to have treated the people well, but now the reigning Bhonsla attempted to make up for the loss of part of his dominions by excessive exactions from the remainder; while at the same time the unhappy peasants were harried by the Pindaris, and other marauders, who, in these days of anarchy, scoured the whole of the Peninsula from Allahabad to the Gates of Calcutta and Madras. If anyone wishes to understand the state of chaos that made the extension of the authority of the paramount power inevitable, he should read the "Papers respecting the Pindari and Maratha wars," and attempt to realise the full significance of the forts now crumbling to ruins in so many villages of Nagpur and Berar. The seriousness of the situation may be gathered from the magnitude of the preparations made by Lord Hastings to cope with it. In 1817 he organised a combined movement from north and south into the country between the Nerbudda and the Jumna, to be carried out by 90,000 regular troops and 23,000 irregulars. With his campaign against the Pindaris we are not directly concerned, but while the troops were concentrating the Marathas broke out unexpectedly in the rear, first at Poona and a fortnight later at Nagpur, where the Residency and the small hill of Sitabaldi behind it were attacked by an apparently overwhelming force. The defenders consisted entirely of the Company's forces—mostly Madrassis—and the issue for a time was doubtful, but in the end the

Hosted by Google

assailants were repulsed, though not till after a quarter of the small garrison had been killed or wounded. Troops were hurried to Nagpur, and, after some further fighting, the Bhonsla chief was deposed.*

The defence of Sitabaldi was considered a notable incident at the time, and, like the defence of Koregaon in Bombay about the same period, it ought not to be forgotten. You will no doubt recollect that during their journey from Calcutta to Bombay their Majesties halted at Nagpur to see the scene of this fight.

Up to 1830 the administration was in the hands of the Resident, and cultivators flocked in from Berar to take advantage of a settled Government. In 1830 the successor to the deposed chief was placed at the head of affairs, and in 1853, on the failure of heirs of the ruling line, Lord Dalhousie, refusing to acknowledge any right of adoption, annexed the country, which, after the Mutiny, was joined with the bulk of the Saugor and Nerbudda Territories to form the Central Provinces proper under the administration of a Chief Commissioner.

The third section of the existing Province—Berar—need not detain us long. Recognised towards the end of the seventeenth century as one of the wealthiest portions of the Mogul Empire, it fell on evil times in the period of anarchy. Marauders from the north poured through the passes of the hills; Gonds from the east, and Hindus from the south, are said to have joined in the plunder, and later on it was subjected to the more systematic depredations of the Marathas, whose right to tribute was definitely recognised in 1716. In 1724 it passed into the hands of the first of the line of Nizams, whose authority, though overlaid at times by the irruptions of the Marathas, just as the country itself is overlaid by the Deccan trap, has ever since been recognised. The Bhonsla Rajas were for a time in virtual possession, but were ousted after Argaum, and shortly before the Mutiny Berar was assigned to the paramount power to meet the expenses of the Hyderabad contingent. A settled rule quickly restored its prosperity, and the emigrants who had fled to Nagpur flocked back again. In 1902 a permanent lease of the Provinces from the Nizam in return for an annual payment of 25 lakhs of rupees was negotiated by Lord Curzon; and the country was placed under the administration of the Chief Commissioner of the Central Provinces. Berar is thus in a curious and anomalous position. Without forming part of British India, it is administered as if it did as far as legal forms will allow, and once a year the dignity of the Nizam is formally recognised by the hoisting and saluting of his flag.

One other point about Berar should be mentioned. Though under Mohammedan rule for nearly three centuries, the vast majority of its people are Hindus, and it has preserved the Hindu character of its organisations, only slightly affected by Mohammedan influences.

The total area of the Province so formed is 100,000 square miles, or rather more than the area of Great Britain, while attached to it are 30,000 square miles of Native States, nearly the area of Ireland. The population is sparse; it now amounts to nearly 14,000,000, a decrease of about a million in the calamitous decade from 1891 to 1901, having been followed by an increase of twice that amount in the succeeding ten years. The recovery from the time of famine in all directions has, indeed, been striking. Bad seasons have not been wanting in the last decade, but the figures of population, showing an increase of 16 per cent., a higher rate than in any other Province, merely corroborate the conclusion to which all indications point that the traces of famine have been obliterated with astonishing rapidity. The Native States population is about two millions. The density of population over the whole area is about 140 to the square mile; in the Native States it is less than half that figure; and in large areas there are not over ten persons to the square mile.

The Province is essentially Hindu, and the people almost entirely rural. Mohammedans

* The Central Provinces escaped comparatively unscathed by the storm of the Mutiny, and the record-rooms in the Government Offices were thus preserved from the destruction that overtook many in northern India. The ponderous volumes of old correspondence in the Nagpur Residency were recently examined and indexed under the supervision of Mr. S. C. Hill, and amongst the documents found was a paper containing the orders of General Doveton for the disposition of his troops in a battle that followed the successful defence of Sitabaldi. It is an interesting document as showing the elaboration with which our generals, long before the days of staff colleges, regulated the formation of their lines in the most minute detail down to the position of the water-carriers and doolie-bearers. A touch of personal interest is given to the paper by a pencilled endorsement of the General's, forwarding it for the Resident to see, and apologising for not doing so in a more formal manner. It is not only at Nagpur that old records have been preserved. In the district offices the mouldering bundles still lie in ancient chests; and among the mass of routine correspondence it is possible that documents may be found throwing light on the conditions of the country when it was emerging from the period of anarchy. Forsyth, for example, has unearthed from the records of Nimar a full account of the last case of human sacrifice—self-sacrifice—at Mandhata on the Nerbudda, in 1822, and if the overhauling of the documents is proceeded with, further light may be thrown on the customs of the time and the problems of early administration.

Hosted by Google

number less than 600,000 in all, and form only about 4 per cent. of the population. Some 13 per cent. are classed as Animists, while Hindus, Jains, etc., account for 83 per cent. There has been a remarkable increase in the Christian population during the last decade, the number rising from 26,500 to 34,700. The Province offers to missionary enterprise a hopeful and useful field which has been eagerly occupied. Even in the most backward parts the little mission stations are to be found, forming centres from which higher standards of life are spreading amongst the primitive tribes. In the towns the missions are equally active, the name of Dr. Hislop, to whom an eloquent tribute was paid by Sir Richard Temple, will not soon be forgotten; and his successors of many creeds and denominations unselfishly devote their lives to the welfare of the people among whom they have cast their lot. They take a keen interest in schools and hospitals, and in many of their institutions a practical training in handicrafts is added to the usual course of literary instruction. No account of the Province would be complete without a reference to the useful and valuable part they are taking in its development.

There are few towns of importance, and only two with a population exceeding 50,000, Nagpur the capital with 101,415, and Jabalpur with 100,151 at the last census.

It is impossible to describe a population so diverse as that of the Central Provinces, except in the most general terms. As seen in their bazaars and villages, the mass of the people leave a general impression of a smaller and darker race than the inhabitants of Upper India. They are simple and informal and friendly, and, on the whole, they are less reserved than the races of the north. There is more familiarity and less of the dignified courtesy that is associated with the east; indeed, there is often in the south an absence of the customary signs of respect that may be mistaken for a want of good will. But it is not; it is merely or mainly the fashion of the country; it was noticed nearly a century ago by Sir Richard Jenkins as a characteristic trait, and it is as far removed from intentional rudeness as is the language of a villager in the north when he uses the familiar "*tum*" in place of the respectful "*ap*." The people are, as Indian conditions go, social and light-hearted; and the backward races are fond of drink to an extent that is rare in India. They organise many village sports; some of the tribes delight in dances representing scenes of love or war; and races between the famous trotting bullocks of the country are popular. The women folk are more in evidence than in the north. The Marathas never took kindly to the *pardah;* the country women are free from Eastern restraint; and in higher circles there is a greater adaptability to the social customs of the West than in Upper India, though there, too, a marked change is now noticeable.

The spirit of the administration, as might be expected in a small Province, is one of close contact between rulers and ruled. There are different aspects in which the advantages of such contact may be viewed. There is, for instance, the sentiment expressed by Mrs. Howden, in the "Heart of Midlothian," when she criticised the removal of the magnates of her country to England on the ground that "naebody's nails can reach the length o' Lunnon." Perhaps that feeling is not without its weight even now, but a far more important aspect is that which looks to fostering the quality of sympathy in our rule. We hear much of a widening of the gulf between East and West, and a growing aloofness between administrators and people. Even friendly critics deplore these tendencies as though there could be no doubt of their existence, but personally I believe them to be mistaken. It would present a much more illuminating explanation of recent events to say that it is the narrowing of the gulf that occasionally troubles the waters. As for aloofness, there are undoubtedly influences in the present day that, taken by themselves, encourage its growth, but my own belief and experience is that the civil officers of Government have now a much more intimate acquaintance with the people and country committed to their care, and a more sympathetic consideration for local needs, and tolerance for local prejudices than they ever had in the past. It is too much the habit to compare the average practice of the present with the brightest examples and the highest ideals of the past, and to forget that tributes to the excellence of our civil administration in India have at all times been interspersed with criticisms of the aloofness and superiority and carelessness of the individual civilian. It would be easy to give examples from the time of the Duke of Wellington downwards, but I take one only from the Central Provinces, where Forsyth tells of an officer who, during eleven years' tenure of a district never once set foot in the hilly portion of it, which covered 3,000 square miles, and was inhabited by 40,000 people. So changed are the standards of the present day that neglect of this description seems incredible.

Hosted by Google

In the Central Provinces, at all events, there is no aloofness. The prevailing spirit there is one of active co-operation amongst the officers of Government themselves, and of close touch between them and the people. Sir Andrew Fraser, himself a local officer, refers to the strength of this spirit as an effective tradition, but it has also impressed outside observers, such as Sir Frederic Lely and the late Sir Edward Law, and has even given rise to the opinion that a Chief Commissionership is the best form of government for an Indian Province, a suggestion which, in my opinion, misses the real lesson to be learned, and which, in any case, is too far removed from the sphere of practical politics to call for consideration.

Two examples may help to illustrate the working in practice of this spirit. During the time of distress and of common suffering in the famine, officials and people were brought into unusually close and friendly relations. One of the results of those disastrous years was to reduce the cultivators of many districts to a state of apparently hopeless indebtedness. It was felt that something must be done, but there was no legal power to do anything. All that the officials could do was to use their friendly offices and their personal influence in suggesting to the creditors a reference of their claims to unofficial tribunals for arbitration. If the creditors would accept a reasonable compromise, the Government offered to make a similar reduction in its claims for revenue and loans. Long and patient negotiations followed with great good feeling on both sides, and in almost all cases the arbitration was brought to a successful issue.

"In the five districts that had suffered most acutely," says Sir Bampfylde Fuller, "debts amounting to some millions sterling were written off, and thousands of families were rescued from degradation."

Another example may be taken from the sphere of local self-government. When Lord Ripon formulated his famous policy, the Chief Commissioner decided that it should have a full and genuine trial. He would have nothing to do with shams, and he adopted the bold policy of placing all the local bodies under non-official chairmen. In the case of district boards it would be premature to say that any great measure of success has been achieved. That may be due to want of funds, though personally I hold that in the conditions of India, without any reflection at all on the business capacities of the people, official chairmanship is essential to the development of a useful system of decentralising local work in the districts. Be that as it may, the experiment has been fully justified in the municipal sphere. The large cities even of Jabalpur and Nagpur have been successfully managed by these non-official bodies; and the administration has been conducted on progressive lines, very creditable in a poor province. The waterworks with which both cities are provided, and the still larger schemes of improvement that are being undertaken in Nagpur, are striking examples of what may be effected under purely non-official management, when it works in friendly and harmonious relations with the official world. I doubt if there is any city in India of the size of Nagpur, where a similar experiment has been as fully tried, and the Government were undoubtedly fortunate in finding amongst the leading citizens men of such public spirit and such liberal ideas as Sir Bepin Bose and Sir Gangadhar Chitnavis to assist in demonstrating the fitness of the inhabitants for the responsibilities placed on them.

A backward country presents a tempting opening to a forceful administrator, and the Central Provinces in their most backward days came under the sway of an exceptionally strenuous ruler, Sir Richard Temple. Then, it has been said, the "distant valleys and mountain gorges that had heard no other sound than the woodman's axe, echoed to the horse-hoofs of the tireless Chief," and the memory still lingers of his rapid progresses with panting secretaries toiling after him. His policy left a deep impress in the Province, and three of the measures taken in his time must be referred to for an understanding of existing conditions, those namely, which relate to—

(1) Native chiefs; (2) Forests; (3) Settlement of the land revenue.

Many thousand square miles of the Province, lying generally in its most inaccessible parts, were then in the hands of chieftains who exercised a varying degree of quasi-independent jurisdiction. There was no certainty as to their status, and no definite rule for their treatment. Sometimes they were dealt with as the commonest subjects. At others they were held responsible as rulers. A clear distinction was now drawn. A comparatively small number were declared to be Feudatories, Native Chiefs, free to rule their States, subject only to political control and to certain restrictions, such as the reference of all death sentences to the Chief Commissioner. The remainder were pronounced to be ordinary British subjects, but were left for the time being in possession of special privileges. They retained

Hosted by Google

control of the police in their estates, and they enjoyed the revenue from excise and pounds and ferries. They were known as Zamindars.

The position of the Feudatories is now one of much dignity and independence, and in a well-managed State the administration reaches a high level. The law courts and dispensaries, the good discipline of the jail, the smartness and intelligence of the police, show what progress has been made from the days of a rough-and-ready patriarchal administration. Occasionally the rate of progress may be too rapid for a primitive people. Grievances are felt or imagined, or there may be intrigues at court and trouble results. A few years ago there was an outbreak in the largest and most remote of the States, which covers an area of 13,000 square miles. The capital was in danger for some days, and there was loss of life before the trouble was put down.

If the development of the country has had, on the whole, the effect of enhancing the dignity of the Feudatories, its result has been otherwise with the Zamindars. The exercise by them of special privileges was anomalous; it was contrary to the law, in the eyes of which they were merely ordinary subjects, and as the country was opened up it could not hope to escape challenge. The Zamindars have had to submit to a process analogous to that which deprived the Highland Chiefs of Scotland of their hereditary jurisdictions. The Government has taken over the police, and is gradually assuming the administration of excise, pounds and ferries, after payment of compensation. Litigation unfortunately arose during these proceedings, and was only terminated this year by a decision of the Privy Council. The way is now open for the prosecution of measures that have long been in contemplation, but have been obstructed by the disputes that arose, for preserving the Zamindars' estates from the danger of being broken up—a danger that unfortunately becomes to people of their class more threatening with the progress of law and order.

In the tracts which have been set aside as forests in the Central Provinces, the State possesses a property of vast size and of increasing value. Outside of Burma no province has an equal area or an equal proportion of reserved forest. In the United Provinces, rather less than 4 per cent. of the total area is so classed; in Madras and Bombay the proportion rises to 11 and 14 per cent. respectively; in the Central Provinces it is 22 per cent., the actual area being 22,000 square miles. Of the tracts originally classed as forest, considerable portions have since been given over for cultivation, and the process is not yet complete. Of the remainder, much is of the poorest description, and would long ere now have disappeared altogether from the category of forest, but for the recognition, when the Province was formed, of the necessity of immediate steps to prevent the wholesale destruction that was in progress. Amongst the jungle tribes the practice was common of burning the forests to secure a few years' temporary cultivation. As an indignant forest officer said, they "had for centuries devastated the forests to form ashes to manure their wretched fields of half-wild grain." We need not, however, condemn them too severely. It may be that in the future their recklessness will appear venial by the side of the recklessness with which civilisation uses up, not merely forests, but the mineral treasures which Nature has spent untold ages in accumulating. To the jungle tribes the forests must have seemed inexhaustible, and were this not the case, they might well have argued that fresh means of cultivation would present themselves with more reason than we now assume that Nature will provide, or our own inventiveness procure, fresh sources of power when we have exhausted those on which our present prosperity is based.

The forest tribes were not the only destroyers. The advent of the railway, and the opening up of the country, brought timber contractors, who threatened even more irreparable damage, and who did, in fact, cause immense and wasteful destruction before Government stepped in. The forests were thus in large measure exhausted when taken over. After half a century of conservation their value is now becoming manifest, though the revenue they yield is still small. In a recent year it was £150,000, not so much as the United Provinces receive from less than one-third of the area. There are a few tracts in which valuable timber is produced, chiefly *sal* or teak, but it is not for their large timber but for their minor products that the forests are most valuable, poles, bamboos, myrobalans, lac, mhowa, and above all for their grazing. The character of the produce has secured a ready acceptance of the principle that forests are maintained primarily for the benefit of agriculture; and it may be doubted whether the administration has been so completely conducted on this principle in any other Province. Subject to certain necessary exceptions and qualifications, all agriculturists can obtain the forest produce they require at specially low rates. As facilities for access to the forests are increased, some restriction in the

Hosted by Google

exercise of these privileges will become inevitable, and a solution may perhaps be found in the grant of definite quantitative concessions to villages established near the forests, whose good-will and co-operation it is desirable to secure, and who but for forest laws would have free access to forest products. People at a distance from the forests would then be left to the ordinary commercial methods of supply.

The preservation of the forests of the Central Provinces is a matter of more than Provincial importance. The whole of the uneven and mountainous country in the centre of India was at one time covered with thick forest. Much of it still is; but many tracts of fertile soil have, very rightly, been brought under the plough, and much of the remainder, being in private hands or in Native States, is being rapidly exhausted. On a hot day in April I have seen the woods blazing near the top of Amarkantak to make a clearance for cultivation, while over the forest below, away to the east, blue smoke wreaths showed that the same process was going on in all directions as far as the eye could reach. In Chota Nagpur, still further east, the destruction of the jungle has been so serious that the Government of Bengal appointed a committee to suggest remedial measures; and attention has been drawn to the increasing violence and frequency of floods in Orissa, owing to the destruction of forest in the catchment area of the rivers. It may be that India will, like other Continental countries, be obliged hereafter to place some restriction on the destruction of private forests, and while public opinion is being educated to this point it is well for the country that in the high tableland where so many rivers have their origin, or whence they draw part of their supplies, there is a large area beyond the reach of reckless or wilful devastation.

The form which the revenue administration takes in an Indian Province is determined partly by the practical consideration of how best to continue existing conditions and customs, and partly by the theories of the time as to the system that is best in the abstract for the people and the country. The Central Provinces offer an excellent example of the working of both these influences. Our predecessors were the Marathas, and in the Maratha country proper it was the custom for the State to collect its revenue direct from the peasantry, without the intervention of any middleman. In Berar this system has been followed, just as it has been in the contiguous Presidency of Bombay. The settlement is made with the peasant proprietors direct, and a percentage given to the headman for collecting it. The headmen and village accountants are hereditary officials, with a status of considerable dignity, the possession of which excites much competition and litigation amongst all who can show any title to it. The revenue is not heavy, and is collected with remarkable ease and absence of friction. In the rest of the Province the Marathas were unable to apply the same definite methods as in Berar. Not only were they invaders, but the people for the most part were of a different race. They took the revenue as they could; sometimes they collected from headmen, sometimes they made the villages over to revenue-farmers and collected from them. Up to the Mutiny, our own arrangements were indeterminate and varied, and when the time came for a final decision to be made, a strong feeling existed as to the advantage of giving a stake in the country to landlords who could act as the natural leaders of the people. The orders were to ascertain the persons best entitled to the proprietary possession of the land, to recognise in them full rights as proprietors, and to make the settlement with them.

This policy was not carried out without difficulty, and in some parts it might almost be said that the authorities had to go out into the lanes and highways to find persons on whose unwilling shoulders the burdens, as they were then regarded, of landlordship might be thrust. But found they were, and the orders were given effect to with a thoroughness that led in the usual sequence of events to an inevitable reaction, and to severe criticism of the policy. That the measures were too sweeping may be admitted, but there were many parts in which the claims of middlemen could not have been overlooked without injustice, and many others in which it might very reasonably be held that the intervention of a landlord between State and cultivator was in itself desirable. Local opinion, however, and local phraseology have never frankly accepted the English conception of landlord and tenant. The landlord is not known by his usual title elsewhere of *zamindar* or land-holder; he is the *malguzar*, the person who makes the revenue good. The distinction is more than nominal; a higher percentage of the assets may be taken from the *malguzar* than is customary elsewhere, and his tenants enjoy an exceptional degree of protection against exaction on his part. From the very beginning the security of the tenants was carefully provided for. Occupancy rights of various kinds were freely recognised, and later on, when good seasons and the progress of the country had enhanced the value of land, more stringent measures to prevent unfair enhancement of rent were taken.

Hosted by Google

Fair rents, with which the landlord has only a limited power of interference are now fixed authoritatively for all classes of tenants alike. The cultivator is thus amply protected; the social and economic effects of the system in other directions can only be judged as the country develops. It tends to make the landlord a mere assignee of rents, and to keep rents themselves at a low level. A weak landlord must accept the position; a strong one endeavours partially to avoid it by extra legal methods. Low rents are not always an unmixed advantage in the long run. All depends on the character of the cultivator. They may encourage careless cultivation or tempt the tenant to sub-let his land and become a petty and tyrannical landlord. One observer has recorded of the cultivators of Chattisgarh that they were better men when the struggle for existence was keener, and it is at least an arguable position that in the backward parts of the Province a less sweeping measure of protection might have sufficed.

The total land revenue of the Province in 1909–10 was £1,250,000, of which a little less than half was contributed by the four districts of Berar, and a little more than half by the eighteen districts of the Central Provinces proper. In Berar the incidence of the revenue per head of the population is just over Rs. 4 or, say, 5*s*. per head, in the Central Provinces it is 1*s*. 8*d*. In the cultivated area the incidence is about 2*s*. in Berar, and 9*d*. in the Central Provinces. Judged by the population, the incidence is high in Berar; it is almost exactly the same as in Scinde, but is higher than in any other Province except Burma; in the rest of the Province the incidence is light, but not markedly so. If, however, regard be had to the cultivated area then the incidence in Berar is by comparison with other Provinces low, and the incidence in the rest of the Provinces is extraordinarily low. Berar is then almost on a level with the Punjab, and its revenue rate is lower, generally substantially lower, than that of any other temporarily settled Province. As a fact, its assessments are generally admitted to be distinctly moderate. In the remainder of the Province the incidence is much less than half of what it is in Berar—only 8*d*. or 9*d*. per cultivated acre—and the assessments have been criticised at times as being unfairly lenient in comparison with other parts of India. That is not the opinion of the local taxpayer. These apparently light assessments are the subject of not infrequent complaint, and in many districts where bad seasons have sapped the resources of the cultivators, it has been necessary to introduce elaborate and complicated methods of easing the burden. The explanation of the comparative unproductiveness of the land settlements must be found in the extremely inferior character of much of the cultivation, the uncertainty of the return, the absence of irrigation facilities, the lowness of the rents in many parts, and the obstacles that make any rapid raising of rent impossible. Any attempt to raise the assessments merely because they appear from statistics to be low would be ruinous to the country, and not long ago, in reply to a representation on the part of the landlords, the Government gave an assurance of moderation.

Enjoying a secure tenure at a moderate rent, the cultivating classes of the Central Provinces require only good seasons to ensure their prosperity. There was a time in the past when, during a succession of such seasons, their prosperity advanced rapidly; and as they were regarded as immune to serious famine, no interruption in their development seemed possible. But the disastrous decade from 1890 to 1900 dashed all these hopes and threw the Province back for a time. Rust, the result of a cycle of years of heavy rainfall, attacked the wheat; one poor season followed another, and when the resources of the people were sadly exhausted, first one famine and then a second came upon them. In the second of these—the great famine of 1899–1900—the Central Provinces suffered almost more severely than any part of India. The direct expenditure on relief operations was over one million sterling in 1899, and nearly two millions in 1900. Over one-fifth of the entire population was at one time in receipt of relief from the State. Since then prosperity has returned, but warnings of the precariousness of much of the cultivation have not been wanting, and in 1907–08 a third serious drought threatened yet another season of calamity. The people were, however, in much better condition to meet the trouble; above all, there was a great demand for labour, and relying on these facts, and on his own intimate knowledge of the country, the Chief Commissioner felt justified in making some departure from the ordinary policy of famine administration. Every famine in India brings fresh problems, and in this case the result showed that the new conditions had been fully and accurately gauged. The total cost of relief was so low—not exceeding £100,000 in all—that the seriousness of the situation has hardly been recognised

Hosted by Google

except by those in intimate touch with the facts; and I cannot do better here than quote the words of Sir Reginald Craddock, as he looked back at the close of his administration in the three famines through which the Province had passed.

"The famines," he said, "were a time of gloom and of almost hopeless despondency. In the first the officers of Government had to gain their experience, and the people had to be helped in spite of themselves. In the next famine the experience had been learned by the officers, yet there had set in a great demoralisation of the people who clamoured for help to an unreasonable degree, and expected Government to do everything for them. Then there came a great change of attitude, and in 1907 and 1908, when there was famine in several districts and severe scarcity in all, it was not a case of helping people in spite of themselves. There was no longer any demoralisation; all we had to do was to put the people in the way of helping themselves, and they did help themselves. I am confident that should Providence have in store any future famine or failure the same spirit of self-help on the part of the people will characterise the administration of relief."

It is in this spirit that the task of helping the people to protect themselves against future failures of the rains has been undertaken. Much has already been done, but what has been done is small in comparison with what has been projected, and if the financial situation permits, the condition of the precarious districts will in another decade be entirely changed. Hitherto the Central Provinces have had but little experience of irrigation. In the rice-tracts, indeed, the crops have been watered, to a certain extent, from tanks, some of these being magnificent artificial reservoirs constructed by former rulers but not specially adapted for irrigation, and others being mere ponds that rapidly dried up in bad years. Outside the rice-tracts there was practically no irrigation, except of small patches of sugar-cane or garden crops. The creaking of the rope and wheel, and the gurgling of the water at the wells, so familiar in the fields of northern India, are rarely heard here.

When the Irrigation Commission visited the Province in 1903 they found public opinion doubtful as to the possibility of any reasonably remunerative system of irrigation on a large scale, and their recommendations took their tone from the local spirit of caution and hesitancy. But they fully recognised the potential value of reservoirs for the construction of which the configuration of the country was specially favourable, and, while unable to hold out much hope of a financial return on the outlay, they recommended a bold policy of experiment. This policy has been fully carried out, and already the attitude of hesitancy has disappeared. Tanks have been constructed in great numbers, chiefly in the rice-tracts; the larger ones deserve the name of artificial lakes, and their value is so much appreciated that the Government is pressed by public opinion to quicken its pace. The largest of these reservoirs, at Ramtek near Nagpur, impounds the drainage from a catchment area of eighty square miles, and is intended to irrigate from 60,000 to 80,000 acres. The experience gained has already justified much bolder undertakings, and projects have been sanctioned for the construction of canals from three of the great rivers, which will irrigate hundreds of thousands of acres, and when completed will revolutionise the economic and agricultural conditions of large areas in the southeast of the Province. On one of these canals work has been commenced.

Admiral Mahan, in one of his works, makes a remark to the effect that war may be excited by the benevolent emotions, but that it cannot exist on them. It is the same with irrigation. Tanks may be made in time of famine without regard to their cost, merely to provide labour for a starving population; other works may be pushed on in ordinary seasons because their need in time of drought is so great as to exclude commercial considerations; but no rapid expansion of irrigation facilities is possible unless the works are remunerative. The taxpayer cannot be called on indefinitely to add to the resources of particular tracts. These principles have been fully understood in the Central Provinces. The great obstacles to supplying the people with irrigation at the public cost are that they have not learned how to use water to the best advantage, and that they are not willing to pay a fair price for it. In plain language, the question to be put to the people is this:—"Can you pay from 2*s.* 6*d.* to 3*s.* per acre for water for your crops?" and a few years ago the answer would have been an indignant refusal. To persons whose rent-rates were measured in annas the idea of a water-rate running into rupees seemed preposterous. But in these few years there has been a complete change. In 1905 the water-rates assessed on the major works then in operation averaged 9*d.* an acre; in 1910 they had risen to 2*s.* 7*d.*; and while a readiness to pay such a rate over the large areas to be

Hosted by Google

watered by the canals may come slowly, there is no doubt that it will come, and there is every hope that the canals will not merely protect the country from famine, but that they will give the State an adequate return on its outlay from public funds and form a lasting monument to the memory of the present chief engineer, under whose supervision they have been constructed or initiated.

The Agricultural Department supplements the work of the engineer by vigorous propaganda, teaching the value of water for irrigation, and how best to use it. In the rice-tracts it has specially concentrated its efforts on this object, and there is every prospect of its success in substituting the superior processes in use elsewhere for the wasteful methods of the apathetic *chamars* of Chattisgarh. It proves by actual demonstration that the cultivator can with care and skill increase the value of his produce by five or six times the amount he pays for irrigation, even in ordinary years. With the work of that Department in other directions time does not permit me to deal, and for the same reason I pass over the success which here, as elsewhere in India, has attended the opening of co-operative banks. If the progress of these institutions continues as it has commenced, not only will a step of which the importance can hardly be over-estimated have been taken in putting the country population in a position to finance themselves, but a valuable training in business habits and co-operation will be given. The village bank bids fair to become a centre of village life, and to restore the old corporate feeling that once animated the best of the rural communities and that threatened to disappear under the disintegrating processes of an individualistic civilisation.

In education the Central Provinces may fairly claim a high rank amongst the Provinces of India. Their village-schools system has been considered by the Director-General of Education sufficiently worthy of imitation to deserve a monograph all to itself; that monograph is one of those rare official publications that are genuinely interesting, and nothing I could say could equal its authoritative and picturesque descriptions. I confine myself, therefore, to noting as an outside observer the prominent part which the village and secondary schools take in the routine of administration. As the official visitor passes from camp to camp, he finds all the village schools on his route *en fête*. If the school-house is far off he may be intercepted on some unfrequented road by the schoolmaster and the village elders, while the scholars are clustered round a table arranged by the wayside. Or, as his train halts for five minutes at a village station, he may be surprised by the strange gyrations and manœuvres of a group of boys drawn up in lines on the platform. On inquiry he learns that they have been marched down from the nearest school to display their proficiency in indigenous physical exercises. There is no doubt that the attention paid to the schools and the practical character of the instruction given, has created a very real interest in them. The proportion of boys at school is higher than in northern India, while female education is, as elsewhere in India, expanding rapidly, and there are now some 30,000 girls in the schools. The change of attitude towards the teaching of girls is one of the many signs of the transformation that is in progress in the East. In his excellent and concise account of the "Peoples and Problems of India," Sir Thomas Holderness says that, "Outside missionary and other circles, there is practically no female education. Popular prejudice against it is firmly entrenched in the institution of caste and early marriage, in the *pardah* system, and in the Oriental view of the mission of women." Ten years ago, or even less, these remarks would have seemed too obviously correct, as regards northern India at least, to attract attention. But they are no longer applicable; they certainly give a wrong impression as regards the Central Provinces. Prejudices are giving way, the tide is turning, and if girls do not stay long enough at school to gain much benefit, they come in numbers that contradict the idea of general opposition. In India, as a whole, the number of girls at school has increased from 385,000 in 1901, to 764,000 in 1910. It has almost doubled in the decade.

The Central Provinces have now long passed the stage at which they could be called backward. In one respect, however, their development still leaves much to be desired. It has been impossible as yet to bring the roads up to the standard of modern requirements. They are being improved, but are still far from being such as the crowded traffic of many parts of the country might legitimately demand. The absence of good trunk roads is in striking contrast to the rest of India. This large area in the centre of the country has not one good through road by which it can be traversed from side to side in any direction. It is not to be inferred that the machine which travels from Pekin to Paris, or from Cairo to Luxor, would be defeated in an attempt to cross the Province, but, as a fact, the motorist from Bombay, on his

Hosted by Google

way to Calcutta or Upper India, turns aside and wisely prefers a long detour through Native States. If he crosses the Provincial boundary he will do well on unknown roads to drive warily, lest he fall into the traps, not of the police, but of the impecunious road-makers. It is worth consideration whether the further opening up of the country would not be more quickly effected by good roads and petrol-driven machines, than by tram or railways. Attempts in this direction in the past have failed, but the development of the petrol engine in recent years, and the extent to which it is now utilised for long-distance traffic, suggest that it may help to solve the transport problem in such a country more cheaply, and, in some places, more effectively than the railroad.

If road communications still leave much to be desired, the cause is to be found partly in the great area of difficult country to be provided for, partly in the poverty of the Province. Half a century ago, roads hardly existed, and in the early sixties, at the time of the great cotton boom, pack bullocks had to be largely employed for transport. The various parts of the Province were then almost entirely shut off from trade with each other. In 1862, wheat sold for eighty seers to the rupee in Chattisgarh; forty-four seers at Jabalpur, and twenty-one seers at Nagpur. The construction of railways has now so entirely altered the situation, that it has well been referred to as much the most important fact in the history of the Province. The railways have allowed of the development both of the agricultural and mineral wealth of the country. They have given mobility to labour, and rendered possible the beginnings of organised industry; they have done much to weld the disjointed portions of the Province into a corporate whole. A through line up the Nerbudda valley was completed in the sixties, when also Nagpur was given a connection with Bombay, and some twenty years later a through line to Calcutta gave Chattisgarh an outlet to east and west. The Satpura plateau has, by the enterprise of the Bengal-Nagpur Company, been opened up by a narrow-gauge line which dips down into hitherto undeveloped parts of the Nagpur and Chattisgarh plains. In the north and north-east there are other lines, and when the much-needed railway from Itarsi to Nagpur, which is now under construction, gives direct communication between the districts lying north and south of the Satpuras, the chief needs of the Province will, with one exception, be fairly well satisfied. The one exception is the cotton country west of Nagpur, the wealth and traffic of which would easily support a considerable development of its railway system.

The effect of the opening up of the country on the condition of the people has been far-reaching, and would afford, owing to the diversity of the circumstance, an interesting field for economic study. Here I can only indicate the impressions I myself received. The Province may, with reference to its agricultural products, be roughly divided into four sections, the first of which is the hilly country in the centre of the Province, and in outlying parts elsewhere, where the main crop is one or other of the small millets grown by the people for their own consumption. Here the effect on the people as agriculturists is as yet comparatively slight. They are being brought within reach of commercial influences by the trade in oil-seeds and in forest produce, but the development has only begun. The mineral resources, however, of the country lie mainly in or near these tracts; and their exploitation has already affected, and must affect much more strongly in future, the condition of the people, and give them some guarantee against the precariousness of their crops. Coal is found in many parts of the Province, in fields of great extent, though not up to the present of sufficiently good quality to encourage production on a large scale. It has long been worked in Chanda in the south, and below the hills bordering the Nerbudda —and more recently a new field has been opened in the valley of the Pench River in the Satpuras. The production is still on a small scale, the largest output yet recorded being 238,000 tons, valued at £72,600 in 1909. The extraction of manganese ore began about twelve years ago, and rapidly assumed considerable proportions, the production in 1907 reaching 565,000 tons, valued at a million and a quarter sterling. The bauxite and iron ores still await their commercial development.

The second agricultural section of the Province is the rice area, which is chiefly the country lying south and east of Nagpur, including the Chattisgarh plain. The area under rice amounts to about 7,500 square miles, and the railway has now given a commercial value to the production of this crop. Formerly in Chattisgarh the surplus produce was stored or rotted. Now the railway cannot easily carry the stocks for export. In the busy season the stations are heaped with bags of rice, and telegrams are wildly despatched to the railway officials and to every authority in India, from the Government of India downwards, that can be supposed to bring influence to bear on

Hosted by Google

railway administration, complaining of the want of transport. The Chattisgarhi is slow to adapt himself to a changed environment, but it may confidently be predicted that here as elsewhere his character will be altered by the facilities which the railways and irrigation together will afford him of bettering his material condition.

The people of these two tracts offer interesting examples of movements that are partly a striving for higher religious ideals, and partly a very practical struggle for social betterment. The lower classes from time to time revolt against the position assigned to them by the orthodox. They strike against the authority of the Brahmans with weapons usually drawn from the Brahmanical armoury. The Kabirpanthis and Satnamis are weavers and chamars who have so revolted. They demand the abolition of caste and the equality of all men, but place restrictions on themselves that seem meant to secure a higher place eventually in the orthodox caste system. In some cases, for instance, not only is eating of flesh prohibited, but lentils and tomatoes are tabooed on account of their red colour. A more purely practical movement arose amongst the Gonds in one district a few years ago. Reverence for the cow was enjoined, but the movement was mainly a temperance one, and was actively encouraged as such by the authorities. Temperance is so much the established rule in India, that in quoting from the appeal which the leader of this movement made to his tribesmen, it is hardly necessary to add that it applied only to a small section of one tribe. There is a familiar ring about the appeal; it shows how much resemblance there is everywhere in the obstacles to human progress.

"There is one great thing," he said, "which has utterly spoilt us, and it is liquor. So long as we don't drink liquor we live like good persons, and when we get drunk we commit as many mischiefs and faults as possible, and do several evil things, and besides, when we go to the bazaar and refresh ourselves in the liquor shop, we all sit together, husband and wife, and squander money in purchasing liquor, and return home with empty pockets without making any necessary purchases for our livelihood, and thus become penniless in the end. That is why the Gonds are called wild and jungly." This crusade against drink had a remarkable success at the time, and its effect is not likely ever to pass entirely away.

The third agricultural area is that where wheat is the chief crop, the Nerbudda valley and the more fertile parts of the adjoining high lands. A transient wave of prosperity came to this tract a quarter of a century back, the value of land rose rapidly, rents which were then subject to fewer restrictions than now were pushed up, and generally the standard of living reached a level at which it could not be maintained in the lean years that followed. Wheat was then commercially the most important of the exports from the Central Provinces proper, where in 1893 it covered 6,700 square miles of cultivation. Since then it has given way to cotton, *jowar* or other crops, and now the total area occupied by wheat in the whole Province is under 5,000 square miles. The cultivators of this area struck me a few years ago as less sanguine about their prospects than those elsewhere; their thoughts seemed to turn more to the good times of the past.

The prosperity of the cotton-tract, on the other hand, has gone on increasing by leaps and bounds. The cotton country is pre-eminently Berar and the western part of the Nagpur plain, but it is extending round the Satpuras and up the Nerbudda valley. Altogether 6,500 square miles of cultivation were under this crop in 1909–10, nearly a third of the total cotton area of India. No other Province gives an equal area to cotton. No Province except Bombay gives half as much. There have been two periods of great prosperity for the cotton country, the first during the time of the American Civil War, and the second in recent years. During the first, it has been said that the cultivators made the tyres of their cart-wheels of silver; in the last their prosperity has had a more tragic effect, and it has been officially reported that a number of suicides were committed "in a delirium of joy at the extraordinary profits of agriculture."

Much has been said of the desirability of improving the cultivation of cotton in India, with a view to obtaining a longer and finer staple. There is no crop to which the Government of India has given, and is giving, more attention, but the experience of the Central Provinces gives as yet little hope of success in the particular direction desired. On the contrary, the cultivators seem to be discarding the finer for the hardier varieties, and the experiments made tend to confirm the conclusion to which their common-sense has led them, that for the present this course is the most profitable. When a cotton plant is discovered that gives an equal and an equally certain yield of a more valuable fibre, they are shrewd enough to adopt it readily; but they are equally shrewd in not neglecting the substance for the shadow. The markets of India

Hosted by Google

are the whole world, and the fibre which is not good enough for England finds a ready sale elsewhere. In 1909–10, the total exports from India of raw cotton were valued at nearly £21,000,000, and of this the United Kingdom took £1,300,000, or about one-sixteenth, Belgium and Germany took between them over £5,000,000 worth; Japan took nearly £8,000,000. It will require very conclusive demonstration of the possibility of growing a long staple fibre to induce the Indian cultivator to risk the loss of his trade with countries where a short staple is in demand. The Agricultural Department has not ceased its efforts to obtain better varieties, but its most promising arrangements are those directed to the immediately practical result of improving the varieties already grown, and above all of providing a supply of good seed for the cultivators.

The cotton-tract is not only the wealthiest but in every way the most advanced in the Province. Here the commercial spirit is most fully developed. There are numerous mills, of which the Empress Mills, at Nagpur, belonging to the Tata family, deserve special mention, both for their size and the excellence of their management. In addition to the large mills, the country is studded with cotton-gins and presses, round which in the cold weather the mounds of cotton glitter in the distance like vast snow heaps. Here, too, there is a great quickening of social and political life, and if the manifestations of the latter are sometimes of a kind to be regretted, the regret is nowhere greater than among the better classes themselves. All this part of the Province shows the influence politically, commercially and socially, of its proximity to Bombay. The following account taken from the Nagpur Gazetteer of the day of a young educated Indian will perhaps bring home more clearly than any formal description the changing conditions which the development of material prosperity, and the progress of education are giving birth to.

"He gets up between four and six, according to the season, and does a little exercise with dumb-bells or Sandow's developer. He then has some tea and goes out for a morning walk, and, coming in before seven, disposes of any work he may have or reads a book. Between nine and ten he bathes and puts on a clean loin-cloth, and . . . goes through his formal morning devotions . . . He will then take his food . . . rice, pulse and vegetables are generally the materials . . . and wheat and *juár* are seldom eaten. Curds are always eaten . . . Among the urban classes tea is drunk with milk and sugar, in cups and saucers of enamel or earthenware. Coffee and cocoa are less popular, but are coming into use . . . In the more advanced community a table-cloth, white or coloured, is spread on the ground and the dishes are placed on it. The people sit round it on stools and take their food from the ground. Tables and chairs are generally kept for writing. Leaf-plates or plantain leaves are still used when a number of guests are invited. After taking his food the clerk will smoke or chew betel-leaf, and then proceed to his office. The practice has lately grown up among the official class of having lunch . . . When he gets home from office about five or six, a man washes his hands and feet, has a little refreshment and plays tennis or goes for a walk. The higher classes of officials now have a club at Nagpur, where tennis, billiards and ping-pong are played. He will come back at 7.30 or 8 and have supper. After this he chews betel-leaf, smokes, and reads the newspaper, or plays on some musical instrument, going to bed about ten."

Conditions are indeed changing rapidly amongst all classes in India, but perhaps the most remarkable of all the changes is one of which we do not take much account in the political and social aspect—the great increase in the demand for labourers, and the consequent improvement in the position of the labourer. In the Central Provinces many circumstances have combined to enhance the value of labour. It is wanted for the mills, and the cotton presses, the mines and quarries, for the railways and irrigation works, apart from the ordinary demands of seed-time and harvest. It is difficult to state the rise of wages in figures, because agricultural wages have always been largely paid at customary rates in kind, but that the labourer can command far higher remuneration than before is a patent fact that is by no means always welcome to their old employers.

"*Malguzars*," says one report, "are often envious of the prosperity of their tenants, but *malguzar* and tenant alike look with disgust on the blatant prosperity of the labourer." It is often said that the great need of India is expansion of its industries so as to secure diversity of employment. In the Central Provinces, I believe the expansion to be proceeding as rapidly as is desirable; too great and too sudden a change in economic conditions is to be deprecated. There is no longer a surplus population dependent on emigration to Assam or the colonies for a livelihood, and the deserted sheds of the coolie recruiters tell of the disappearance of a once remunerative occupation. The problem of famine administration has assumed new forms, and drought, except when very serious, may lose much of its terror. The depressed classes are bestirring themselves, and the higher classes are beginning to take a new interest in their welfare. Agriculturists bemoan the increased cost of

Hosted by Google

cultivation, but they have the compensation of higher prices. With more reason the recipients of fixed salaries complain of the difficulty of maintaining their standard of living, and the State is faced with the possibility of a large increase in the cost of its establishments. The change is not confined to common unskilled labour. There is a much greater demand for the skilled mechanic, and the next generation of Indian workmen is likely to develop a much higher degree of mechanical skill than its predecessors. The effect of the training in technical schools, and still more of the training in the great workshops on the railways, and at such places as the gun-carriage factory in Jabalpur, is only now beginning to make itself felt, but it means the creation of a race of skilled artisans with all the independence of that class. The rapid emergence of the ordinary labourer from a condition that gave him a bare subsistence to one of comparative comfort, or even of comparative affluence, and from a state almost of servitude to one of freedom, can hardly fail to have a profound effect on the constitution and character of Indian society.

In the past the great internal problems of India, apart from the primary question of the maintenance of law and order, have been mainly those connected with the land, the method of its tenure, the equitable adjustment of proprietary and cultivating rights, and the collection of a fair revenue for the State in such manner as to be least burdensome to industry and to the progress of agricultural improvement. These problems have lost none of their absolute importance, nor can they ever do so in a country the dominant factor of whose welfare must always lie in its agriculture. But their relative importance has diminished; they no longer overshadow other questions to the same extent as before. Owing to the rise in prices the burden of the revenue has been lightened, apart from all the advances made in recent years, and especially during the Viceroyalty of Lord Curzon towards a less rigid and more liberal system of collection. The revenue weighs less heavily on the people, and its collection gives less trouble to the authorities. At the same time the opportunities for making a livelihood otherwise than by the land are multiplying rapidly, and new openings are presenting themselves, not to the labourers alone, to whom reference has already been made, but to the higher classes as well. Formerly Government service and the law appealed to the educated youth, almost to the xclusion of other methods of livelihood; now the possibility of success in other careers is widening his outlook, and giving him larger views as to the measures necessary to promote the development of his country. In the Central Provinces the educated classes have keen political and commercial instincts, and it is interesting to note how their public men apply themselves to questions of definite practical importance — sanitation, technical education, the encouragement of industries, and the development of irrigation. Their representatives on the enlarged Imperial Legislative Council have from the beginning borne an active share in the work of that body. They have not merely taken their full part in the discussion of matters of Imperial interest, but have kept provincial affairs in evidence with a persistency that might almost suggest a diplomatic design to expedite the formation of a Provincial Council of their own to which such local matters might be transferred. The same active spirit animates them in the sphere of commerce and industry. The cotton trade has shown the profits to be made in business, and lawyers and landholders join in organising or financing manufactories or presses, or in following the lead given by the European in the exploitation of the country's mineral resources, and so finding employment in prospecting work or remunerative investments in the maganese quarries. The people are thus preparing themselves to play their part in the future developments that must come; and it is satisfactory that this should be so, as their interests must tend to encourage the promotion of local industries for dealing with the mineral ores in which their country is so rich.

Further signs of adaptability to modern conditions, and readiness to take advantage of new openings, may be seen in the establishment of independent medical practitioners in the towns and even in the large villages, and in the acceptance by educated men of posts in the manufactories. At the Empress Mills, Sir Bezonji Mehta gives the B.A. a welcome which, to judge from recent correspondence in the *Times*, the graduate does not always receive in similar cases in this country. It is time that we revised our ideas of the unchanging East. India at least is changing rapidly, and recent political measures have given the people a keener interest in its development, and a stronger determination to play their part in influencing that development on lines of their own. There is a new consciousness of power, which will react outside the merely political sphere and quicken the pulse

Hosted by Google

of the country in all its movements. There is every sign that the Central Provinces will not be behindhand in responding to the altered conditions. That they may share to the full in the times of peace and prosperity that we hope and believe are in store for the whole country, must be the wish of everyone who has ever come under the charm of that picturesque Province and its interesting people.

DISCUSSION.

The Chairman (Lord MacDonnell) said the author had commenced his paper with an apology for bringing forward an account of his old charge, which, he said, would probably not interest his listeners. He (the Chairman) thought the audience would agree with him in saying that the paper had been most interesting. To the stranger it gave an admirable idea of the multiform life of the Central Provinces, and he thought to all Central Provinces officers it might almost be called an index—an index of the most interesting book that it had ever been his lot to read. For he (the Chairman), too, was one of Sir John Miller's predecessors as Chief Commissioner of the Central Provinces; and, as the author had developed his theme, his mind had gone back to the years that he had spent in the Central Provinces. He could bring back to himself concrete instances of all the remarks in the paper, especially those dealing with the picturesqueness of the country, and of the free and open life which it was the privilege of all Central Provinces officers to lead. The author had not mentioned the camp life which every Central Provinces officer underwent for many months in the year, or the facilities for sport which were open to him, and which in no other part of India could he enjoy in the same perfection. An incident which had occurred in his own experience had come to his mind as the paper was being read —the first time he ever went on a great hunting expedition under the charge of the then Inspector-General of Forests, or the local forest officer in the Central Provinces, one of the most accomplished shikaris that any Province in India could produce. Those were days when a young officer in the Central Provinces came in contact with men who did not count their tigers by scores but by as many days as there were in the year. The gentleman he was referring to, Mr. Thompson, in taking him out on his first tiger-shooting expedition, had told him that in his early days he had been deputed for the purpose of clearing a particular tract of country of tigers, and before he left it he had killed a tiger for every day in the year. It was an education to be with Mr. Thompson, not only for the experience that he gave of the shikari, but for his extraordinary knowledge of jungle life and his perfect understanding especially of bird life and the forests. There was nothing that gentleman did not know, and, sitting in the evening in their tents, every voice of the jungle carried to him a particular meaning. He (the Chairman) should have taken some exception to what the author had said in regard to ancient remains in the Central Provinces, but any criticism which he was disposed to make upon that point had been completely answered by the excellent slides which had been thrown on the screen. He himself was greatly struck with the solidity of the ancient structures, and when it was remembered that those structures had come down from the Gond times, one would be able to see that even in those old days, before the Central Provinces were subjected to any outside influence, there was a great school of architecture there—more remarkable for its solidity, perhaps, than for its grace of execution. In the Central Provinces, as the author had shown, there were not only ancient Hindu monuments, but also the indigenous and aboriginal monuments which he might call the Gond type, overlaid by the Mohammedan monuments which were found in Burhanpur. The remarkable thing was the great complexity of the races which were found everywhere in the Provinces. He supposed in the early days of the history of India those highlands of Central India were the refuge of the aboriginal tribes, who had remained to the present time perfectly unaltered and uninfluenced by the civilised life which surrounded them on all sides; they still led the jungle life which they must have led for 2,000 years. They were the most perfect and fearless beaters for game that were to be found in any part of the world. In regard to what the author had said about forests, he quite agreed that the Central Provinces administration had been always most careful in its dealings with the people in connection with forests. The population was very sparse, and there was no necessity for Government to interfere and deprive the people of the custom, which they had enjoyed for so many years, of enjoying forest produce. It was impossible, owing to the absence of means of communication, that it should be otherwise. Until the Central Provinces were pierced, as they were not at present, with the means of communication by which forest produce might be extracted and made an article of commercial value, it was best to allow the people to enjoy their ancient rights. In regard to settlements which the author had mentioned, one thing had to be borne in mind, namely, that the rates of revenue which were collected by the Government in India could not be compared with each other acre by acre. The incidence per acre in one Province could not possibly be compared with the incidence per acre in another Province. For instance, taking the two cases of Berar and the Central Provinces, in Berar he understood from the paper that the ordinary rate of revenue was at 2*s*. per acre, while in the Central Provinces it was only 8*d*. or 9*d*. The explanation was that in Berar the crops were so much more valuable than they were in the Central Provinces. Berar was the most productive cotton country in India, producing cotton of excellent character, and consequently

Hosted by Google

fetching a far higher price in the market than did the millets and the other inferior grains which were produced in the Central Provinces. Consequently the cultivator in Berar could afford to pay to the Government a larger revenue, though not a proportionately larger revenue, having regard to the value of the crop. The question of land revenue settlements was a very burning question in India some time ago, and a charge was brought against the British Government for being excessive and exacting in its demands. That question was very wisely made the subject of a most careful inquiry by Lord Curzon when he was Viceroy, and a resolution was prepared in which the revenue systems in force in every part of India were carefully analysed and compared with each other. He (the Chairman) had left India when that resolution appeared, but he thought a more complete and perfect answer to the charge of excessive exaction on the part of the British Government on the natives of India could not have been made. He himself believed—and he had had, before he left India, opportunities of forming a judgment on the point in connection with certain inquiries made in relation to famine—that there was no country in the world in which the claims upon the cultivator of the soil were apportioned or assessed with more care for the interest of the cultivator than was the case in India, especially in the British portions of India. It had been his province to compare the rates assessed in the British districts with those assessed in the adjacent native districts, and in every case in which a comparison was possible it was in favour of the British system. The author had made some remarks in regard to famines, and the sufferings which the people had had to bear during the last five years of the last century. That was the only point on which he at all experienced a feeling of disagreement with the paper. The author said that each famine brought with it its own questions and its own difficulties. Like all other questions, when the ground principle of famine relief was grasped, the difficulties which any particular famine presented to the administrator were no longer of any great magnitude. The essential principles of famine relief were explained in language of which he always thought with the utmost respect by that great Commission which sat in India and reported in the year 1880. It was presided over by a most distinguished officer, Sir Richard Strachey, and the Secretary of the Commission was that most eminent Indian officer, Sir Charles Elliott. They laid down principles which he (the Chairman), who had had some dealings with famine, believed were the last words to be said in regard to famine relief. They said: "The great object of saving life and giving protection from extreme suffering may not only be as well secured, but in fact will be far better secured, if proper care be taken to prevent the abuse and demoralisation which all experience shows to be the consequence of ill-directed and excessive distribution of charitable relief." He had heard with great satisfaction Sir John Miller's words in regard to Sir Reginald Craddock's treatment of the last Central Provinces famine. He had not heard of it before, but he had expected that Sir Reginald Craddock would take that view of famine relief—that the duty of the Famine Administrator was not to give charitable relief where it could possibly be avoided, but to enable the people to work out their own salvation by affording them the means of earning a livelihood. When in the Central Provinces he (the Chairman) had the pleasure of knowing Sir Reginald Craddock and had formed the highest opinion of him, and he was glad to see that in dealing with famine that gentleman took the only true and proper method possible, a method which was first advocated and proclaimed by the Famine Commission of 1880. Sir John Miller had also referred to the changes that had come over the Central Provinces—changes so great in some directions that he (the Chairman) could scarcely keep pace with the swiftness with which they had been effected. He spoke of the possibility of there being a Council founded in the Central Provinces. He (the Chairman) thought that was quite possible. It was the direction Indian administration was now taking; but he trusted that the time was far distant when to a Legislative Council would be added the Executive Council which was now being created in other Provinces. The Central Provinces were still peopled by a homely race, and although Bombay was near, and the educated natives of the Central Provinces were imitating Bombay in all that appertained to commercial advancement, the vast mass of the people were still in a very backward stage of national development; and they naturally, as in other Provinces—and he hoped it would long continue to be so—looked to the district officer and the officials of Government as their best advisers and protectors in difficulty and adversity. We were living very fast in these times, but it might be possible to live too fast in matters of that description. The prestige of the English officer among the people of India still lived, and, although it was quite right and proper that to the educated natives of India larger spheres of activity and higher employment should be given, England must be prepared, if that policy was carried far, for a less efficient Government in India than she had hitherto demanded. She must remember that Englishmen—from the training they received in India, when brought face to face with conditions of life calling for self-reliance, resolution, readiness to meet emergencies as they arose, determination to maintain law and order at all costs, and the firm resolve to administer the law with perfect impartiality to all people—had imprinted on the administration the character which England had up to the present demanded. If such Englishmen became scarce, the same resolute action, the same freedom from local ties, the same degree of impartiality could not be maintained in the administration. The men who would replace them would themselves be resolved and determined to act up to the lessons which they had learnt from their

Hosted by Google

English colleagues, but there would not be for many years to come that freedom from influences and that impartiality which had always been the mark of the Englishman in dealing with the natives of India.

Sir Benjamin Robertson, K.C.S.I., C.I.E., said he had been acquainted with the Central Provinces for nearly twenty years, and he was about to return to India in a month or two to take over the administration of that part of the country, where both the life and the people were extremely fascinating. He would like to add his voice to the testimony which the author gave as to the superficial nature of what might be called the lack of polish which was noticeable amongst some of the people, particularly in the south of the Province. As an example of what an excellent stamp of people the Province contained, he could not do better than quote the case of the Mahratta patel of Berar. He did not think there could be found anywhere in India a finer specimen of the Indian cultivator. If he (the speaker) were to specify the chief points which covered the time of his acquaintance with the Central Provinces, he should perhaps refer to the wonderful recovery from the famines which marked the close of the last century and the beginning of industrial development which had occurred since the present century began. He noticed his friend Mr. Manson in the room, and he would like to mention in connection with his name the remarkable progress which had been made in parts of the country through the extensions of the Bengal-Nagpur Railway. When he (the speaker) was under the Right Honourable Chairman, he was the Deputy Commissioner of a small district named Balaghat. It was about thirty miles from the railway, by a road on which there were two unbridged rivers, and at that time the telegraph line had only just been extended, by the Chairman's efforts, to the headquarters of the district. That was the state of affairs in 1892. Twelve years later he happened again to visit the place when manganese mining had been undertaken. The railway had by that time been built, and, as he was returning in the afternoon to the main line, he was told if he desired to do the journey more quickly than by the ordinary train he might catch the "Manganese Special." That showed what progress had been made in twelve years. Progress had been the watchword of the Province, and he hoped when he went out there it would still continue to be so. In conclusion, he begged to propose a vote of thanks to the author for his interesting paper.

Sir James Wilson, K.C.S.I., in seconding the motion, said all must have enjoyed the very clear and interesting account which the author had given of the fascinating Central Provinces—in fact it had made him (the speaker) almost wish that instead of being sent to the Punjab he had been sent there. One point in connection with the administration of the Central Provinces—which perhaps did not apply to other Provinces in India —was that they had had the advantage of having a succession of very able rulers chosen from outside. He did not know what the people of the Central Provinces thought about it, but in the Punjab they would not like to have all those outside governors, however able they might be. He hoped the tradition of having Chief Commissioners from outside was now broken as, although he knew the Central Provinces had derived much benefit from the able men who had successively ruled them, there were great advantages in having a man to govern a Province who knew its people and whom the people knew. Some time ago Sir Denzil Ibbetson, who was then a member of the Government of India, had consulted him about what should be done when Sir John Miller in the ordinary course would move on. Sir Denzil, who had himself been Chief Commissioner, said that he felt very strongly that it was rather hard that the Central Provinces should almost always be governed by men from outside, however good they might be, and that it was time, if it was possible to find a man inside the Provinces who was fit to be Chief Commissioner, to appoint that man. It was in consequence of that opinion, that ultimately Sir Reginald Craddock was chosen to be Chief Commissioner, and he thought the results proved that Sir Denzil Ibbetson was perfectly right. Under Sir Reginald Craddock's vigorous administration the Central Provinces had advanced in every possible way. It was also a matter for congratulation that another Central Provinces man had been found in Sir Benjamin Robertson, under whose rule the Provinces would no doubt make a further advance. In addition to seconding the vote of thanks to the author of the paper, he desired, on behalf of the Indian Committee, to thank Lord MacDonnell for so kindly taking the chair that afternoon. Lord MacDonnell had told them something about his own connection with the question of famine in India. He (the speaker) had had the privilege of helping to work out the recommendations of the Commission over which Lord MacDonnell had so ably presided, and he knew what an enormous benefit that Commission had conferred upon the peasantry of India by its careful investigation of famine problems and the wise advice it had given, which had been adopted by all the local Governments in India.

The vote of thanks was then put and carried unanimously.

Sir John Miller, in acknowledging the vote, said he desired to express his personal gratitude to Lord MacDonnell for having, amidst all his business and the very heavy affairs which were devolving upon him at present, found time to preside that afternoon. He further wanted to say that it was not only his own appreciation of Lord MacDonnell's kindness, but he felt sure that if he could speak for the Central Provinces they would all feel pleased

Hosted by Google

to know that the most distinguished of their former Chief Commissioners had found time to attend and hear a paper on the Provinces.

The Chairman said it had been a great pleasure to him to attend that afternoon. He had been more than repaid by the courtesy with which the audience had listened to him, and the pleasure which he had experienced in listening to his old friend Sir John Miller's paper.

TWENTIETH ORDINARY MEETING.

Wednesday, May 8th, 1912; Colonel Sir Edouard Percy C. Girouard, R.E., K.C.M.G., D.S.O., Governor of Northern Nigeria (1908–9), and of the East African Protectorate (1909–12), in the chair.

The following candidates were proposed for election as members of the Society:—

Prashad, Rai Bahadur Ashtabhuja, Bansi Ditt, Basti, United Provinces, India.

Reindorf, Christian J., Accra, Gold Coast Colony, West Africa.

The following candidates were balloted for and duly elected members of the Society:—

Halford, George, A.R.C.A., 11, Foden-road, Walsall.

Japp, Henry, 507, Fifth-avenue, New York City, U.S.A.

The Chairman, in introducing the author, said that Mr. Morel needed no introduction to a British audience, or indeed any audience. His devotion to African interests, his single-mindedness in contest, and his achievements for African advancement, were very well known to all. Mr. Morel had temporarily, for that night at all events, abandoned one sphere of action for another, and the speaker was sure that all who lived in Nigeria, or who had the interests of that country at heart, would welcome his remarks as a witness or critic of what had been done there. Mr. Morel had written a book on the subject even before he visited West Africa. People who visited the colonies were frequently possessed of an insatiable desire to write a book on the subject, even on short acquaintance. It became a form of mania in some instances, in others a disease, one which apparently had not been investigated by the schools of tropical medicine, unfortunately for the Governments who had to endure them. He would say about Mr. Morel's book that it was surprisingly good. It might have inaccuracies, but on the whole it was read with very considerable interest in West Africa. In 1909 Mr. Morel had had the opportunity to visit West Africa, particularly the Nigerias. As a result of that visit, a series of brilliant articles appeared in the public press, bearing upon the progress, the past, and the future of the two Nigerias. These articles were expanded into a book which certainly was to-day almost a standard treatise upon the mental, moral, and manual work which had been accomplished in Nigeria, particularly within the last ten years. The speaker had himself spent two of the happiest years of his official life in Northern Nigeria, but Mr. Morel would have more up-to-date information to give, and he (the Chairman) would content himself with saying that it was a country of a vast and surprising interest. It was almost like stepping into the "Arabian Nights," after leaving the coast, to go into the old Mohammedan empires, which ceased in 1493, although their laws were continued in the rest of the Mohammedan world down to the present time, with the treasures, universities, and all the panoply of the government of the Middle Ages. It had been the speaker's duty to carry on the work of a man who had devoted six years of his life to creating Northern Nigeria, adding to the dominions of the Crown 250,000 square miles and 10,000,000 people. He was loath to give up his task, and had, in fact, to be forced from it; and while the speaker could quite understand that any Governor who had the honour of ruling in Nigeria for his Majesty should feel such sentiments, none could possibly leave the country with the same feelings as the founder of it had. It was borne in upon the speaker all the more clearly that his primary duty was to carry out a policy so successfully inaugurated by his predecessor. A very short acquaintance with the country itself, and with the Civil Service, which had grown up around the Governor, had convinced him that during the time he held the Governorship it would be his duty to adopt the views of his predecessor. Certain details it was necessary to change, but in essentials nothing was altered. In such a country changes came up from day to day, but in all those changes he believed that the spirit if not the letter of a policy which was inaugurated by his predecessor was followed from year to year. He was glad to know that his successor had worked upon the same lines. It would be his principal pleasure in looking back upon his work in Nigeria —and he thought he could also speak for Sir Henry Hesketh Bell, his successor—if, when Sir Frederick Lugard returned to Nigeria he saw that, on the foundations which he had laid so well, an edifice had been erected to which he would find no objection, and to which it would only be necessary to add wings to create almost a celestial structure. All Nigerians were especially glad and satisfied that the creator of Northern Nigeria, as it was known to-day, had been chosen by his Majesty to unite the two Protectorates. The work was a great one, and he was quite sure that the genius which created Northern Nigeria would be able to unite the two colonies into one homogeneous whole. The speaker was sure that the great, even the paramount, interests of Southern Nigeria would not be forgotten in such hands; and that the work carried out for many years by Sir Walter Egerton, as collaborator with Sir Frederick Lugard and himself, would be duly appreciated, and utilised to

Hosted by Google

mould a country which would be an honour to the Crown. The one factor necessary, the one upon which Lugard founded his policy—and the speaker was readily able to agree with that—was the utilisation of the native populations in their government; utilisation of the genius which they undoubtedly possessed—some in a marked degree—for their benefit in the future. It was a policy which aimed at the development of what he might call British African nationalism; it was a kind of slow-setting cement, to be applied to a corner stone. It was not possible to hurl a people from the eighth to the twentieth century in twenty months, or twenty years. If, however, gradual development and evolution of the people were allowed, he felt confident that stable government would be established in British West Africa.

The paper read was—

BRITISH RULE IN NIGERIA.

By E. D. Morel.

On July 21st, 1796, for the first time in the history of the world, a European gazed upon the waters of the Niger. Unutterably weary, as weary as the wretched beast he alternately rode and drove before him, half starved, racked with fever, with no better protection from the sun's rays than an old top hat—of all awful headgear to travel with in Africa—in the crown of which he carried his notes, wearing a much frayed blue fustian coat originally ornamented with gilt buttons, with the hair almost removed from one side of his head owing to the interested attentions of a native friend, who thought European hair made good medicine, and had helped himself freely, the pioneer of European exploration on the Niger beheld, and in beholding solved, in part at least, the mystery which had puzzled the western world for centuries. He was, of course, a Scotsman—and his name was Mungo Park. The Niger, he saw, flowed eastwards, but where? Into the Congo, into the Nile, into the ocean, or did it lose itself among swamps? Six years later Park again set out to complete the reading of the riddle. For 1,500 miles he followed the course of the great river, came to shipwreck at the rapids of Bussa and perished—exactly how has never been ascertained. He perished, but he had pointed the way his countrymen were to tread. To-day, thanks in the first place to the enterprise of our explorers, Richard Lander, Denham and Clapperton, Joseph Thomson, and to the enterprise of our merchant-statesmen, Macgregor Laird and Sir George Goldie; and, in the second place, to the activity and genius of Sir Frederick Lugard, British rule extends over a vast portion, and the most fertile portion, of the countries drained by the Niger and its affluents. In the two Protectorates of Northern and Southern Nigeria—soon, a most desirable consummation, to be amalgamated or federated under the Governorship of Sir Frederick Lugard—we have to-day a dependency which is not merely the most considerable and wealthiest of all our tropical dependencies, India of course excepted, embracing as it does an area of 332,960 square miles, and thus equal in size to Germany, with Italy and Holland thrown in; but one which, from several points of view, is replete with administrative and other problems of quite exceptional interest.

There is Nigeria on the map—still a closed book to the majority of the public, but big with future possibilities; a country of which more and more will be heard with every year that passes. I thought it well to have it permanently on view during the paper, not assuredly because I suspect the intelligence of my audience to be on a par with that of the lady who, when she heard Nigeria mentioned at a tea-party, remarked that it was, indeed, a beautiful creeper—confusing it doubtless with wisteria; but because it may help you, and me too, as we go along. I confess to some little trepidation at my boldness in talking to you about Nigeria under the eagle eye of our Chairman, who has been supremely responsible for the government of five-sixths of this country—to its lasting good—and whose dislike of inaccuracy in statement is known to be of the fiercest possible character. Many years of close study of its history and conditions from this end, a recent journey thereto, on behalf of the *Times* and the *Manchester Guardian*, and a very lively interest in its peoples and its problems—to these, however, I can at least lay claim. Most of you are old enough to remember that we had formidable rivals to a portion, at least, of Nigeria in the French. That was the *pre-entente* period, and a very lively period it was. It was the patriotic thing to do in those days to wax tremendously excited over places and tribes of which one had never heard previously. I recall an incident in the editorial sanctum of a highly patriotic newspaper, about a town of no particular importance rejoicing in the name of Nikki. I called in one evening—not at Nikki, but at the editorial sanctum—and found the editor poring over West African maps and metaphorically tearing his hair. By way of greeting, he burst out: "Where is this

Hosted by Google

Nikki, anyhow? I'll be shot if I can find it! Some God-forsaken hole in an African swamp; and yet, for all the fuss they are making over it, it might be the headquarters of old Nick himself." I found it, and, much mollified, he capped his previous performance by remarking that I had turned up in the nick of time.

And now to more substantial diet.

The word Nigeria embraces a region which offers the most diverse and, indeed, startling variations of scenery and human type. That no doubt, in part explains the fascination it exercises over those whom fate leads thither. I will first speak to you of the south. The greater portion of the southern region is covered with dense forest and bush, with an outer fringe of mangrove swamp, which really represents, I think, the steady encroachment of the land upon the sea. Beyond the forest belt the country gradually breaks up into wooded slopes, savannahs, and park-like areas. In the western province, however, the land, though forested, is more open. Man has here destroyed the forests to some extent for his needs, but in many respects improvidently, and a busy Forestry Department is endeavouring to arrest further destruction and to regulate the usage and exploitation of forest wealth. Through this forest and swamp the great river, after its journey of 2,250 miles across the continent from west to east, passes on its way to the sea, bifurcating just below Abo into the Forcados and the Nun, and spreading into a fan-shaped maze of creeks, which reduce the whole country to a series of islands of every shape and size. That is the delta. This deltaic region is indescribably impressive; so infinite; so silent; seemingly, at first sight, so tenantless of human life; in parts, so melancholy and uniform; in others, so beautiful. It resembles some primeval world in which uncouth monsters, such as Professor Challenger's creator is telling us about in the *Strand Magazine* just now, ought by rights to put in an appearance. At first, as you enter it, there is nothing but mangroves as far as the eye can reach on every side, mangroves raising their skeleton-like roots from the mud, the home of many curious and repulsive forms of fish and insect life. But gradually, as you make your way inland, and the banks solidify into firmer ground, the vegetable life becomes increasingly varied. Palms, bananas, ferns, and occasionally the grey upstanding bole of the silk-cotton tree appear, to be succeeded in turn by dense forest growth, interlaced with a net-work of giant creepers. The slide gives you an idea of the Nigerian forest. It is hot, very hot and moist inside, like a much-heated greenhouse; and, to the lover of nature, full of things lovely to look upon—birds, butterflies and flowers, strange and gorgeous. But full, too, of ants and thorns and fierce poisonous plants.

This region is one of the wealthiest in tropical products in the world. Once you come to the alluvial soil it will grow almost anything. It abounds in valuable timber, mahoganies, walnut, satin, rose and dye woods; in gums, kolas, fibres and numerous oil-bearing plants of value. Its future as a cocoa producer will almost certainly be considerable. Cotton it will never grow, I think, in appreciable quantities. But above all it is renowned as the natural home of that most beneficent of trees to man—the oil palm of commerce, the most valuable commercial asset of West Africa, which, judging from its fertility, must be absolutely inexhaustible.

Here you see casks full of palm oil being shipped on board a steamer for Europe, where it is used chiefly in the manufacture of soap and candles. The oil expressed from the kernel is now used for edible purposes, being a constituent of margarine. The fruit of the oil palm plays an indispensable part in native social economy, and any attempt to restrict the free use of it by the native, besides being false policy, would defeat itself. It is used by the native as a diet, a beverage, for lighting, cooking, soap-making, as an ointment, for medicinal purposes, and so on. Its leaves and branches serve for roofing material, clothing, the manufacture of fishing-nets, baskets, as fuel, and for many other purposes. In addition to all its domestic uses, the fruit of the oil palm forms the paramount national industry of the south for export purposes, and gives employment to hundreds and thousands of natives—men, women and children. Nearly five millions sterling worth of palm oil and palm kernels were shipped from Southern Nigeria last year, and the kernel trade is but in its infancy. And the output of that labour—which, bear in mind, is free labour in the fullest sense of the term—by these Nigerian producers gives employment to tens of thousands of European wage-earners: a factor in Afro-European relationship which, were it fully appreciated at home, might tend to modify some curious ideas which appear to be prevalent as to the idleness of the West African native, and tend also to increase public interest in the country.

So much, but a brief glance indeed, at

Hosted by Google

Southern Nigeria's vegetable resources. What of the Southern Nigerian himself, without whose mighty muscles, and without whose willingness to use them, all this natural wealth would be lost to the world's industries? In the central and eastern provinces nature deals hardly with man. For half the year the best part of the country is under water. Think what that means for the inadequately sheltered human being who lives in it. Nature is very terrifying in the Nigerian forest region, and mortality —infant mortality especially—is very heavy. Of those that survive, it may be truly said that it is the survival of the fittest. A luxuriant vegetation fights for every inch of tenure with man; tornadoes sweep shrieking through the sombre shades; torrential rains convert the narrow paths connecting one village with another, or leading from the village to the nearest creek, into a raging torrent. Heaven's artillery exercises its fullest powers. Man fights for his life against nature, against disease, and he fights the spirit world, which it is small wonder he should have evolved from his inner consciousness in the midst of that terrific natural environment—a spirit world full of terrors and needing much propitiation. And that fight is, perhaps, the hardest of all, for it is incessant, not leaving man even in his sleep, for then his dream-soul goes a-wandering, and gets into all kinds of scrapes. I don't know whether you will share my view when I express the opinion that it is little short of miraculous that under such circumstances, cut off from the outer world by sea on the one side, by dense forests and human enemies on the other, the Southern Nigerian should not have remained wholly stagnant, the lowest of the low in the scale of humanity. The thing which has saved him has been the stimulating influence of trade. A born trader, he trades from village to village. He has stated market days—regular markets, sometimes at very long distances, which he visits periodically. The whole population trades in the commodities of the country. And when we superior Europeans first appeared in the country, and asked the Nigerian to trade in his own kith and kin, he raised not the least objection, not having reached our then level of sanctity for human life—when covered with a white skin. Now we ask him for his palm oil, his rubber, and his gums, and he is just as pleased to trade with us in those. And he is a keen bargainer— as keen and as quick as any European, as the Europeans who trade with him will tell you. But although successful bartering requires a considerable amount of intelligence, the Southern Nigerian has more in him than that.

Here is a slide which will be more interesting to you when I explain it. It is part of a native rubber plantation outside Benin City, and it tells a wonderful story—a story of what the Southern Nigerian is capable of under a just and common-sense administration. Fifteen years ago Benin City was the centre of a priestly theocracy, of a distinctly unpleasant type. The capital earned and merited the title of the City of Blood. They did not sacrifice as many people proportionately as we find it necessary to put into lunatic asylums or prisons, perhaps, but still they sacrificed a good many, and Benin was not a particularly pleasant country to live in. To-day it is one of the most peaceable districts in the Protectorate, inhabited by some 150,000 enterprising and intelligent people with a keen eye to business. Some years ago it was suggested to the Bini people by the Forestry Department, the value of whose labours not only in an economic but also in a political sense it would be difficult to exaggerate, that if they went in for making rubber plantations they would by and by reap a profit. The Binis believed in the Forestry officer who told them that, and they took the matter up. The Department supplied the seeds, gave advice, trained a few natives in the art and sent them round the villages. At the present moment no fewer than 700 Bini villages possess their own rubber plantations, which, of course, belong to the community on the basis of the native social system. They are increasing yearly, and other tribes are following the example. In the Bini country alone there are over one million and a quarter trees whose present estimated value is £165,000. Many of the trees are now tapable. The plantations have been kept up entirely by the natives themselves, who are now learning to tap scientifically. The Department undertakes to dispose of the rubber for the communities, which ensures their getting the best price going. So gratified are the Binis at the result that when, a little time ago, tapping operations began and the proceeds began to roll in, the chiefs and villagers insisted that the Administration should keep a larger share of the profit than the modest royalty it had reserved for itself. They insisted that the Administration should take one-third, and, despite the Governor's objections, would consent to no other arrangement, which has now

Hosted by Google

been embodied into law. That is a true story which speaks volumes for the Administration and for the Bini, and when you are told that the African native is fit for no other *rôle* than that of hewer of wood and drawer of water for the white man, I venture to hope you will remember it.

A word on the western province before we go north together. This is the home of the Yoruba people, and Lagos, situate on an island, is the present capital of Southern Nigeria, a wonderfully cosmopolitan and up-to-date place, boasting many fine public buildings and numerous adjuncts of civilisation, from hospitals and engineering shops to a bacteriological institute and a race-course; but, in my humble opinion, already much congested and not an ideal site for the capital of the united Nigerias. Its streets are a picturesque sight, thronged with a busy, gaily-dressed crowd, and you will meet on its outskirts native traders from as far north as Sokoto. It is cursed with a bar, which the retiring Governor, Sir Walter Egerton, one of the most active and hard-working officers who has ever held supreme control in West Africa, has been making successful efforts to remove by throwing out a couple of moles on either side of the harbour, a gigantic work which, when completed, will make of Lagos the Bombay of West Africa. This is a country of great native cities scattered about the 80,000 miles of hinterland. Nowhere in native Africa are there such numerous and such large human agglomerations—a couple, Ibadan and Abeokuta, possessing well over 100,000 inhabitants, while two or three dozen others have between 40,000 and 8,000 each. Both for their qualities and defects the Yorubas are a most interesting people. Apt traders and farmers, they possess considerable intellectual qualities. Unhappily, and speaking generally of course, the system of education we have introduced among them—a thing of shreds and patches, ill thought-out, or, rather, not thought out at all—is having the tendency to break up their native forms of government, and to produce a political instability with undesirable results. These problems have been somewhat neglected, and will require both firm and tactful handling. A people of great promise, one realises when one moves amongst them—almost as much, indeed, as in the north—the stupidity of the cackle about idle Africans. Here is a picture of a native market in Yoruba land. Scores of such huge markets are to be met with all over the country—as busy a scene, I imagine, as you could find in any part of the world.

There are two ways of reaching the uplands of the north. By the railway from Lagos to Jebba, where you cross in a steamer pending the completion of the bridge across the Niger; to Zungeru, the capital of the Northern Protectorate; and so to Minna, where this line, for which the Southern Nigerian Government is responsible, joins the line from Baro to Kano, built by the Northern Nigerian Government. At least, you can do that now; but you could not when I was in the country eighteen months ago. That is one route. The other route is by boat up the great river itself to Baro, the starting-point of the Kano line. I will ask you to follow me up the river. We shall enter the Forcados branch of the Niger, work our way in to Warri, a trading station of some importance and an administrative centre, through narrow, serpentine creeks of peculiar beauty, whose deep green waters reflect the nodding palms above them, into the main stream below Abo. Up the river for 400 miles, in ten days' steaming, crowded with interest and ever-varying scenes. For the first few days the banks on either side are densely wooded, abounding in cocoanut and oil palms. Fishing villages and canoes are numerous. Here is a magnificent specimen of a Nigerian canoe-man—perfectly proportioned as a Greek statue. Round the villages of neatly-thatched huts are clearings, bright with the tender green of the banana or young maize. The bird fraternity is much in evidence—in the shape of blue and white and black kingfishers, ibises, cranes, marabous, egrets, spur-winged geese, crown birds, and so on. Now and again a hippopotamus will raise his dark head from the waters—then silently disappear. On the sand banks, which are frequent, ever shifting, and a considerable obstacle to navigation, you will occasionally see a crocodile basking in the sun. The sun beats down shrewdly, and it is very hot. You almost lose the sense of time during these reposeful days, gliding onwards on the bosom of the great river. The bustle and stir of European life seem very remote as your little paddle-boat churns its way onwards day after day, inducing a sense of dreamy calm. When the sun goes down, dyeing the waters with glorious hues, the insect world, which, indeed, has not been conspicuously dormant throughout the day, wakes into full activity. Tiny gems of emerald light float towards you from the shore—fire-flies, and exquisite they

Hosted by Google

are. Other visitants are not so pleasant, and if the lamp is anywhere in the vicinity, the cloth which is being laid for "chop" will soon be literally black with flies of every kind and description, with ponderous beetles, moths, and flying ants, while the inside roofing of the sun-deck above you will be alive with billions of mosquitoes. You share your victuals with these nocturnal visitants, and while some of them are varying their diet by sucking as much nice fresh European blood as they can manage, you are retaliating by absorbing quantities of them in your soup. But one soon gets accustomed to these commonplaces of African travel, and when you turn in, inside your mosquito curtains rigged over your camp-bed on deck, and listen to the vague murmurs from the mysterious world of night all round you and breathe in the aromatic scents from the forest hard by, you would not, on the whole, change your quarters for a king's ransom.

And you learn so much—amongst other things, initiation into pidgin English in converse, or attempted converse, with your "boys" whom you have picked up down south. They may be full-grown men, but custom requires that they should be called "boys." A very short and obese railway surveyor I met in the wilds of the north possessed as a "boy" a stalwart Hausa of splendid proportions and fully six feet high, who could have tucked my little friend under his arm and walked off with him with ease. What particular idea has guided the construction of the barbarous lingo known as pidgin English is beyond me. But the result is something of this kind. Does your boy wait upon you with some particular request you feel too lazy to attend to at the moment, in lieu of saying "presently," you tell him to "wait small." Are you disturbed in your day dreams by a loud-voiced squabble, and wish to threaten the offenders with dire consequences, instead of saying something mild such as, "Stop that infernal row or I'll break your neck," you are supposed, in order to make yourself vocally comprehensible, to go into a rigmarole of this kind: "Stop dem palaver one time or big palaver go lib." Personally, I always found the modest "Shut-up" quite sufficient, which increases my scepticism as to the value of pidgin English. Do you wish the lamp lowered, you gravely tell your boy to "Kill dem lamp small." "Chop him," sounds blood-thirsty, but it only means "Eat it." Gripping his body firmly with his two hands, your cook volunteers the statement, "Sick catch me, massa," meaning that he has developed a pain—in his head. In such cases I recommend Epsom salts as an infallible cure.

And so we proceed up past Onitsha, a busy trading station, and famous for a native market whence the representatives of divers and erstwhile hostile tribes congregate together at stated intervals. And here it is that for the first time one sees in appreciable numbers, alongside the semi-naked Pagan, the Mohammedan in his flowing robes and turban. Most interesting is it to watch on market day the dug-outs owned by wealthy native merchants coming across the river in the early morning, most of them flying banners with some strange device, with drums beating, and the rowers putting up their monotonous chants, full of people, of sheep and goats, and piled up high with merchandise of all kinds. From Idah onwards the scenery undergoes a complete transformation. The land rises into high valleys and slopes. Mountains detach themselves from the horizon. The vegetation becomes scarcer, and massive boulders of grey granite make their appearance. In the vicinity of the banks a superior form of cultivation is now to be detected—yams and guinea-corn in parallel lines and raised ridges. Cattle can be observed. It is a new world we are entering. We stand at the threshold of the Mohammedan North. We cross that threshold at Lokoja, where the Benue, the Niger's great eastern tributary, falls into the parent stem. A magnificent view can be obtained of the confluence from the summit of Mount Patte behind Lokoja.

Here at this active centre of trade, the commercial halfway house between north and south, we plunge into the picturesque civilisation of Islamic Nigeria. We shall not here see, indeed, that civilisation at its best—its ceremonial, its courts, its political and social machinery. For that we must go further north still. But Lokoja, as the southernmost Mohammedan trading *emporium*, is replete with interest and humming with native life. Here it was that on January 1st, 1900, Sir Frederick Lugard hoisted the Union Jack as first High Commissioner for Northern Nigeria.

It has been said—I think Sir Percy Girouard was the author of the phrase—that Northern Nigeria has suffered through having been too easily acquired. By this, I take it, he meant that if its acquisition had cost the British taxpayer more, and had been attended by considerable fighting in which many of our officers had

Hosted by Google

lost their lives, public interest in the country would have been keener. There is unhappily a good deal of truth in that remark. The achievement has been carried through so expeditiously, and with such absence of fuss and advertisement, that the public simply does not realise what a big thing it is. In a few years—from 1900 to 1906—at a minimum of expense and loss of life, a country 250,000 square miles in extent, containing some ten million inhabitants, was brought under control, under circumstances—mere physical circumstances, alone—of the utmost difficulty. And this result was achieved by a handful of white officers and officials, and a handful of black soldiers, with, at their head, a man of untiring energy and administrative capacity, in a land almost virgin of adequate routes of communication, unmapped, largely *terra incognita*, inhabited not by a few Pagan tribes lacking all cohesion, but in great measure ruled by able and astute Mohammedan Emirs, who for a century had held a sway, nowhere seriously disputed, over the mass of the population; rulers who could put many thousand cavalry into the field besides a great mob of foot-men. I do not think the annals of the Empire record a more brilliant feat. It was much more than a mere success in arms, for although at one moment the military danger was pressing, it never matured, and the actual resistance, though not on one or two occasions to be despised, was strictly localised and relatively insignificant. No, it was above all a feat, not of military prowess, although I do not under-rate that, but of statesmanship which, having for its goal the essential and necessary establishment of supreme British control, yet determined that once that control was accepted, the government of the country should be left, under Residential advice and supervision, in the hands of the country's natural rulers; that the existing social structure should not be shattered and, of course, that the religious beliefs of the people should be respected. From the outset Sir Frederick Lugard made it clear that our military action, forced upon us by circumstances which at this distance of time we can all unite in admitting to have been compelling, was directed not against the people of the country or their institutions, but against certain individual rulers from whose excesses—for which those rulers were but partly responsible—the people themselves suffered in their persons and property. This was the mainspring of Sir Frederick Lugard's success. But even so his work would have lacked permanence save for two factors: the character of the men whom he selected as Residents, and without whose sagacity, tact and firmness the position won would have been gravely compromised, and the circumstance that when he left the helm in 1906 he was followed in supreme authority by a man who not only continued the policy Lugard had so well begun, but who brought to the problems awaiting solution—and most vital of all the problem of land tenure, the basis of the entire social fabric of the country—a penetrating and sympathetic insight, a power of imagination, and a grasp alike of fundamentals and of opportunity, which crowned the edifice. That man is our Chairman to-night, and I beg him to believe that I venture upon this modest tribute in no spirit of flattery induced by his presence. I should have said as much and probably a good deal more if he had not been with us. Between them these two men, and the small band of experienced Residents assisting them, have laid the foundations of the only effective and just system under which the African tropics can be administered—governing on native lines. It is no disparagement to Sir Henry Hesketh Bell, the retiring Governor of Northern Nigeria, who has been in charge of the Protectorate for the past two years, to say that he found the edifice in being, and has loyally contributed to its maintenance. Of the land policy inaugurated by Sir Percy Girouard—the substance of which is the legalisation of the native system of tenure, the elimination of the speculator in land, and the foundation of a future land revenue—it may be confidently asserted that it is a bold and magnificent piece of constructive statesmanship. The Colonial Office—Lord Crewe was then Colonial Secretary—is to be warmly congratulated upon having sanctioned it. It is a policy which must rejoice all those who have pleaded for a scientific treatment of these great tropical African problems, and who realise that lack of comprehension and bungling in regard to indigenous systems of tenure have been primarily responsible for many disastrous mistakes, not only in Africa, but elsewhere.

With your permission, we will now talk round the slides. Here is Baro, the starting point of the railway to Kano—now complete, save for one or two bridges—and the terminus of our up-river journey. To convert this spot into a suitable landing-place, it had to be literally turned inside out. The high hill which you see immediately facing the

Hosted by Google

river had to have its flank cut open; a slipway, a jetty and workshops, had to be evolved out of nothing, and the erection of buildings undertaken on the hill-top, to place the European staff out of range of the mosquito-infested swamp which, at that time, was Baro's chief attraction. The tremendous energy of the Director, Mr. Eaglesome, was not satisfied with dwelling-houses. He must needs convey water to the hill-top too, to say nothing of a hospital, which combination doubtless was responsible for saving many a young fellow's life. It is characteristic of the man who built this railway and of the methods employed, that Mr. Eaglesome's office at Baro boasts of nothing more luxurious than a cement floor, bushpole rafters, and an iron roof covered with thatch. Eighteen months ago the railway had only reached a point known as the Kaduna crossing, and the rest of the journey to Kano had to be done on horseback, a matter of nine days' trekking. I say, had to be done, but I mean no disparagement to the railway. For personal enjoyment in travelling through a country of this kind, give me a horse between my knees and the freedom of roaming over the great open spaces, before any railway in the world.

So early one morning, as the stars are paling and the crisp air starts fresh and chill, we start off on a journey replete with the most vivid interest, difficulties not worthy of mention, and humorous incidents not a few to keep us cheery —a nine days' trek to Kano, followed by a thirteen days' trek into the Bauchi highlands, where the tin we hear so much about is to be found, and eleven days' back to the advancing railway by another route; some six weeks in the saddle, including stops, six weeks of elbow room, six weeks of days in the glorious sun, and of nights under the equally glorious stars, six weeks of life—and the God of the open air be thanked for it. Of good augury is the start, which begins with the amusing sight of watching the evolutions of the cook over the head and back of his horse, an animal which the cook—coming as that worthy did from the Bini country, where they don't grow horses—had perhaps never seen, had certainly never attempted to mount. Four times the unfortunate *chef*—who was the only fool I met in Nigeria except the Court fool of the Emir of Zaria, whose portrait you shall presently see—clambered upon the back of his *Rosinante*, and four times she deposited him with unnecessary emphasis upon various parts of his anatomy, amid peals of merriment from the rest of the crew. For his part, being of a grave and melancholy disposition—the gravity of complete mental vacuousness—and rejoicing in the name of *Minehoho*, he saw no joke in the matter at all. And here, together with my Mohammedan head-man Kolo, who does not appear in the picture, and whose virtues I should like to commemorate in verse had I the power, are my companions for many unforgettable days, the indispensable carriers, flotsam and jetsam of Africa, great wastrels and altogether delightful people. At least, I found them so, even when, on one occasion, they got drunk on palm wine, and got me into trouble with the fraternity of local butchers in a Hausa town, and although they sometimes lost their way, reducing me, for a time, to the tortures of thirst.

Now and again in our peregrinations, up hill and down dale, past flourishing native settlements and past the ruins of erstwhile prosperous communities, laid waste in the forays which preceded the advent of British rule, through lonely stretches virgin of human life, and through waving fields of guinea-corn, sugar-cane and cotton—we cut across the track of the future line.

Here is a busy scene of rail- and plate-laying. The handful of Royal Engineer officers on the Baro-Kano line have beaten all records in the matter of rail-laying in tropical Africa, which is not to be wondered at, for the vocabulary of the Northern Nigerian men does not contain the word "impossible," they can make bricks without straw, and the building of this line at a maximum of speed and a minimum of cost has been a veritable *tour de force*—being constructed, moreover, under a system of native labour which, I should imagine, will henceforth be the model to be followed in other parts of Africa: a system in which the Political Officers, the Native Administration and the labourer have been hearty co-operators in a common end.

On the fourth day out we reach Zaria, one of the great red-clay walled cities of Hausaland, boasting a long line of kings, and many wise and holy teachers, rising out of a vast cultivated plain dotted with fantastic piles of granite resembling—where all is mediæval, or perhaps biblical would be the best description—those mediæval castles which you can see scattered along the heights which border the Rhine.

This slide will give you some idea of the picturesque ceremonial surrounding the native rulers of Northern Nigeria. It represents the Emir of Zaria accompanied by his old-world

Hosted by Google

cavalry, standing at the door of the tent lent him by the Administration on the occasion of last year's Durbar, which was held at Zaria with great pomp and circumstance, many Emirs congregating together for the occasion with their thousands of mounted followers. And this slide represents the same Emir—one of the most learned and astute of the Fulani Emirs—on trek, visiting some of his outlying districts. The curious headgear you observe on some of his attendants is a straw hat made in the Nupe country, and often worn on top of the turban. It looks rather top-heavy in the picture, but in real life does not appear in any way incongruous.

Five days beyond Zaria again—the last two covered on a fine native road, dotted with magnificent trees through as smiling and fertile a land as one might wish to see, where great herds of white hump-backed cattle graze contentedly, passing numerous native caravans of long-distance traders, men and women with their little children, clad in multi-coloured raiment, carrying all manner of articles on their heads, driving convoys of heavily laden pack donkeys and pack bullocks, and droves of oxen, sheep and goats before them, with an occasional camel or two—and we come within sight of the most remarkable native city in all Africa, the far-famed Kano, with its great enfolding walls, thirteen miles in circumference, from 20 to 50 feet high, and from 20 to 40 feet thick at the base, pierced by thirteen deep gateways. Here is one of them, with platform and guard-house, and massive doors heavily clamped with iron, with its written records dating back eight hundred years.

Kano, of which you see here a section, is worthy of a lecture in itself. First built in the reign of our King Henry VIII., and famed throughout Africa for the industry of its inhabitants and the fertility of the province of which it is the centre, it has excited the astonishment of every European who has visited it. When he first entered it, Lugard exclaimed that it exceeded anything he had ever seen "or even imagined" in Africa. Its market, perhaps the most celebrated in Africa, is a wonderful sight. Here you may see from 5,000 to 7,000 people daily buying and selling in the great open square lined with clay-built booths—a sight which, in its colouring, its setting, the brilliant sun above, the clamour of voices, the bustle and dust, is fairly bewildering. A tiny corner of it is here given. At no spot in Africa can you see such an astounding medley of different tribes—the keen-featured Hausa, the Fulani, the thick-lipped Kanuri from Bornu, the Nupe vendor of glass and brass ware, the tall, lithe, fierce Taureg from the far north, with the black veil half drawn across his face, the supercilious white-skinned Arab from Tripoli, who occupies a special quarter in the town. The merchandise on sale is even more varied. Every kind of native cloth produced from native looms, and noted for some special peculiarity or excellence from all over Nigeria, is here to be met with, together with Manchester cottons; every kind of locally manufactured agricultural and vocal instrument; all sorts of meats, vegetables and fruit, and plants for medicinal and dyeing purposes; local silver ware and cheap trinkets from Europe; leather work—such as saddles, bridles, despatch bags, leather cases for Korans, both locally manufactured and imported from North Africa; swords and daggers, some of beautiful workmanship; rough pottery; raw silk, indigo, potash, and heaven knows what besides. In one corner a cattle sale is going on; in another a bargain is being struck over some donkeys; in another horses are being led out for inspection—and fine beasts some of them are; in yet another, local dancers are performing to the sound of the inevitable drum furiously beaten. It is at once a market, a fair, and a gossiping centre which, for hundreds of years, has been renowned throughout fully one half of the African continent.

To my regret, I take leave of Kano, *en route* for the Bauchi highlands—a long trek through gradually ascending country, often wild and beautiful, very sparsely populated, bearing much evidence of desolating years of inter-tribal warfare and raiding. This slide will give you some idea of the country. It was never completely conquered by Mohammedan Fulani, Hausas, and Kanuri, and contains an agglomeration of pagan tribes, speaking many languages.

They go about almost naked. Some of them are daring barebacked horsemen, shooting with great accuracy with the bow. They weave beautiful grass mats, grow tobacco and cotton, and are learning to tap, without destroying, the numerous rubber trees which are found in many parts of the country. Tin occurs in patches all over this region, in almost every case alluvial, deposited in the beds of the rivers. The industry would appear to have a solid future before it, and the Bauchi country is less unhealthy than are the low-lying regions. But I am inclined to think that its healthiness, together with other features concerning it, has been somewhat exaggerated. Certainly, in my opinion, which

Hosted by Google

is worth very little if anything—for I am no expert on the subject—the premiums at which some of the shares in the tin companies which have been floated are standing, are not justified. It would be a pity if the undoubted mineral future of the Protectorate were jeopardised through its getting a bad name with the investing public by premature Stock Exchange booms. The Gold Coast offers a recent and flagrant example of the inconvenience of these manœuvres. The railway which will in part tap the field is making good progress, and there are plenty of opportunities for capable young fellows of the right stamp with a moderate capital who are prepared to go out and really work and mine.

The predominant, though not the ruling, race throughout Northern Nigeria are the Hausas, and this slide is a typical specimen of a Hausa man. Their exact origin is wrapped in mystery, although it is generally thought that the original stock came from the valley of the Nile. They are a remarkable people; on the whole the most remarkable people probably in Africa. Their language is the commercial *lingua franca* of a considerable part of Western Africa, and they have many sterling qualities. Great agriculturists and traders, they have developed a form of indigenous civilisation under the influence of Islam and trade connections with Tripoli—and probably in remoter days with Egypt—which has no parallel in Africa. For centuries they have grown their own cotton, spun it into beautiful, enduring cloths, dyed it with dyes of their own manufacture, principally indigo, which is found in a wild state in the country, embroidered it with elaborate and tasteful designs, and sold the finished product over an enormous expanse of African territory. The Kano looms practically clothe the inhabitants of the desert regions which lie between Lake Chad and the southernmost oases of Fezzan. I venture to hope that that industry, that health-giving (under Nigerian conditions) and elevating industry, will not only not die out, but will be encouraged by Government to expand and develop. Sympathetic as I am towards the work which is being performed by the British Cotton Growing Association in its attempts to create a large export industry in raw cotton from Northern Nigeria, and sensible as I am of the just claims of commerce between Britain and Nigeria, I contend that it would be little short of a national disaster to the peoples of Northern Nigeria if the Administration interferes in any way to restrict or hamper the native weaving industry. I should much like to see an exhibition held in London of the products of the Nigerian looms. It would astonish a good many people, and a taste might grow up among the wealthier members of this wealthy community for these beautiful articles, for beautiful and artistic they are. Apart from the tens of thousands of Nigerian men and women to whom the industry gives direct employment, and the many more tens of thousands to whom it gives indirect employment, upon its maintenance are dependent several other handicrafts which, with its disappearance, would also die out. The same argument applies to the leather work, the tanning, the smelting and other crafts in which the Nigerian is proficient. The export of dyed goat-skins from Northern Nigeria has now attained a considerable figure.

The next slide is that of a pure-blooded member of the Fulani race, over whose origin scientists and writers on West Africa are continually wrangling. The type here shown is that of a young Fulani girl belonging to what are known as the bush or cow Fulani, the nomadic herdsmen and shepherds from whom have sprung the born leaders of men and spiritual reformers who, early in the nineteenth century, welded the Hausa States into a homogeneous entity, and who form to-day the ruling caste throughout Hausaland. In the pure type the complexion is an olive brown, the features refined and regular, the limbs delicate and graceful. It was my good fortune to meet with several encampments of these nomads off the beaten track—a wonderful people to come across in the heart of Africa. They are the owners of most, if not all, the vast herds which move over the face of Hausaland. I leave the Fulani more rapidly than I should like, but time is getting on.

Here is one of the Fulani Emirs on the march surrounded by his gaily dressed followers. The Emir of Kano is the veiled figure in the centre. You must in imagination clothe his retinue in reds and greens, and blues and whites, and yellows, paint under their horses' feet a red-brown soil, and above their heads a sky of blue to obtain any idea of the picture as it appears in real life. One of the predecessors of the present Emir astounded the bluff and simple sailor, Clapperton, the first white man to visit Kano, in 1824, by putting him through his paces as to the differences of opinion between the Christian sects, and winding up by asking him if he were a Socinian or a Nestorian. I am happy to say that I was spared this disconcerting experience in my conversation with his successor.

Hosted by Google

The Jāfi, or mounted salute, is an exciting form of courteous salutation indulged in by the Nigerian Emirs and their followers, which it was my privilege to witness on several occasions. They charge down upon you at full speed, reining up their horses short and flinging up their right hands with a shout. On one occasion whilst breakfasting at the morning halt by the side of the great white road through the Kano province, I was the recipient of one such salute which, for the fraction of a second, appeared to me to be likely to end in my camp table, of somewhat flimsy construction, my breakfast and myself disappearing in the midst. However it only resulted in the deposit of a little extra dust in the porridge.

Here you see a somewhat similar charge by the quilted horsemen of Bornu, who resemble old crusaders; a Nigerian hunter who has attached to his forehead the head of the ground horn-bill, the *Burutu* bird as it is called, the more successfully to approach the game he is stalking; a Hausa trading woman, many thousands of whom you meet travelling up and down the roads, fine specimens of womanhood up to a certain age, with a free and graceful carriage, and the classical dress of antiquity; cooking meat—a Frenchman might call that picture *rognons brochette à l'Africaine.* Of Nigerian meat such as you see it in the markets, the less said the better.

I promised you a sight of the Emir of Zaria's Court fool. Here he is. Every inch a fool, the quaintest figure ever I saw as it sped along at a great rate in front of the Emir returning from a religious ceremonial. Judging from his countenance, the assistant seems to be qualifying for the office.

These two slides, which are my concluding ones, represent first a gathering of Nigerian Mohammedans clad in their best attire on their way to celebrate the festival of the Sallah, which marks the close of the fast of Ramadan. The second shows a section of a vast concourse of Mohammedans at prayer, bowing themselves before the supreme Creator of the Universe. At sunrise and at sunset, in every Hausa village, you will hear the cry to God Almighty pealing out, and an impressive sound it is, while men make their silent devotions, quietly, without ostentation—and then go their several ways.

I would like, with your permission, to say a few words about the subject of these pictures. They represent a great force in Nigeria which it is idle to attempt to ignore, still more futile to rail against; and which, in the administrative sphere, it would be positively wrong to try and undermine. I am speaking of this force in Nigeria, not elsewhere be it noted, and I assert, without fear of contradiction from any responsible person, that this social and religious force has, on the whole, raised, and immensely raised, the intelligence and the general standard of the races among whom it has become implanted. It has largely assisted in moulding in the heart of Negro Africa a civilisation, a system of civil government, of jurisprudence and of ethics, immeasurably superior to that which surrounds it in the non-Islamised pagan belts, and which it is in the essential interests of the people should be maintained by the British power, not weakened or invaded. It is founded upon the Koran, and whatever shortcomings the Koran may contain from our point of view as a moral guide, we must remember that administratively speaking we find ourselves, in Northern Nigeria, in the position of trustees for the people of the land. To those people, to these our Mohammedan subjects in Nigeria, the Koran is at once the constitution, the charter and the Bill of Rights. In the appeal to his faith many of us are prone to see in the Mohammedan mere fanaticism. It is a mistake. In that invocation the Mohammedan is appealing to his constitutional rights. It is, I think, often overlooked that Islam is not only a religion but a social system, and that in attacking the religion you attack the fabric upon which society reposes, and that in attacking that fabric you attack the religion. The two are one. An excellent point about that quality is the recognition by the rich of their responsibility towards the poor. With us our constitution is not connected with our religion, and in the result which ensues the Mohammedan could find perchance as much to criticise as we may find to criticise in Islam. Let us beware of doing anything to undermine the constitution of our Nigerian subjects, by introducing legislative and judicial machinery which does not, and cannot, prove a substitute for what they have. If the national scheme of education which has been set up in the Protectorate, upon admirable lines, is properly understood and supported from home that danger need not arise, at least through any initiative taken locally. But the danger cannot be said to be non-existent so long as there is any fear that the home public is improperly informed, and led to erroneous conclusions as to the character of the great religious and social force with

Hosted by Google

which we are called upon to reckon in Northern Nigeria, and, in an increasing measure, in the south. A published study of what Islam in Northern Nigeria is, and what it is not, is much to be desired for public enlightenment at home.

I feel that my paper has been wretchedly inadequate to convey to you a tithe of what I should have wished to convey. I can conceive of nothing finer, nothing more calculated to stir the imagination, to bring out the uttermost in the moral fibres of a man, nothing more inspiring than the privilege of participating in this work of Empire-building as it is now being performed in Northern Nigeria. For here is the true article. None of your cheap and shoddy jingoism. None of your "damned-nigger" theories to corrode the work of Government. Building, not destroying; strengthening, not pulling down native institutions; preserving the natural heritage of the people—the land—for the people, not robbing them of it for the benefit of speculators; respecting those who in the Providence of God have come beneath the *ægis* of our protecting mantle; helping them along their own natural lines to expand to a fuller consciousness of civic responsibility; applying a policy which, while upholding the social fabric, the lofty courtesies and the national characteristics of an ancient race, will grant to its members opportunities and security which, without us, they could never have acquired. That is the real Imperialism. That is the task which is being carried out in your name in the vast spaces of Nigeria.

I am no blind worshipper at the Imperial shrine. I am acutely conscious that the word Imperialism has been too often prostituted to serve ends the reverse of noble. But in my opinion the constructive work for good which has been and is being performed in Nigeria cannot be over-estimated.

Of the men who are carrying it out amid enormous difficulties, one can say in Kipling's poem of "The Sea Wife":—

> "The good wife's sons come home again
>   With little into their hands,
> But the lore of men that ha' dealt with men
>   In the new and naked lands;
>
> "But the faith of men that ha' brothered men
>   By more than easy breath,
> And the eyes o' men that ha' read wi' men
>   In the open books of death."

These men are entitled to claim not our sympathy merely in their task, but our comprehending, our active and intelligent interest. Let us support them. Let us support with our sympathy and with our wealth their efforts to sustain a form of administrative policy through which alone the rule of the white race in the African tropics can be made a blessing and not a curse to their inhabitants, by which alone we, as a people, can justify our claim to the over-lordship of Nigeria. It is no less their due, than it is our manifest obligation.

DISCUSSION.

The Chairman, in inviting discussion, referred to the paper as a thoroughly instructive and accurate exposition of the present position of affairs in Northern Nigeria. After an absence of some years he could not, of course, associate himself with every sentiment which Mr. Morel expressed, but he could heartily endorse the broad and general views of native government to which Mr. Morel had given expression. When he (the author) had spoken of a certain duty which this country owed to Nigeria the speaker was again in sympathy with him. He would mention a matter to which Mr. Morel had not referred—namely, that while the speaker was in Nigeria, more than 10,000 northern Nigerians disappeared annually over their eastern boundary to proceed on the great journey from Lake Chad to the shores of the Red Sea, to do their duty towards the centre of their religion. Any foolish or intemperate interference with such a faith, which was both a faith and a rule, would prove disastrous. Only recently at Port Soudan, his aide-de-camp, who had been with him in West Africa, was greeted by two Hausa people, who, on his expressing surprise at recognition, explained that he had been seen by them two and a half or three years before in the native towns of Nigeria. That incident showed, the speaker thought, the character of their feeling, the faith which had come down through the centuries, and which should not be disturbed too rudely.

Dr. John Pollen, C.I.E., said that he spoke as one who knew nothing of Nigeria, beyond the fact that he had devoted his first-born to the service of the land, but he desired to express his appreciation of the admirable paper by Mr. Morel. He had heard many papers in that hall, but to none had he listened with so deep a sense of gratification as to the one delivered that evening. He admired particularly the great spirit of Imperialism displayed by the author, coupled, as it was, with that sympathy for others without which Imperialism was as nothing. He congratulated Mr. Morel upon having thrown so much light on the administration of a great dependency, which reminded him of his early experiences in India in a part of that country which greatly resembled Nigeria. The noble spirit of the lecture should certainly have an excellent influence upon the rising race of Englishmen.

The vote of thanks was carried unanimously and the meeting terminated.

THE PHILIPPINE HAT INDUSTRY.

The native hat industry in the Philippines is developing as a result of increased demand for the articles in the United States and elsewhere, and the work done by the Philippine Bureau of Education in stimulating the people to increased production. The hats are commercially known as "bamboo," but most varieties are made from other materials. Hat exports in the fiscal year 1908 amounted in value to £34,000, and in 1911 to £61,600. The demand for these hats is said to be growing rapidly among American farmers, particularly in the Southern States. The selling price of the cheaper grades is about one shilling per hat, and the articles are serviceable, comfortable, cheap, and presentable. The Philippines also produce "Panamas" and hats of special weave. The "bamboo" hats include not only those made from bamboo fibres, but often from the buri palm. Bamboo hats proper are sometimes known as the "Baliwag" hat, as they are principally made in the town of Baliwag, Bulakan Province. This class also, however, includes the "Pulilan" hat, made in Pulilan, which is important in the export trade, and which, to jobbers, has come to mean a coarse bamboo hat. The American Consul-General at Hong-Kong states that the fibre for the bamboo hats generally is obtained from the Kawayan bamboo, the common bamboo of the Philippines, and generally consists of the layers of fibres in the middle sections of the plant torn apart, soaked, steamed or boiled, dried, bleached, and otherwise specially prepared. The varieties of hats produced from the buri palm are numerous. Four valuable hat fibres are produced from the palm—raffia, generally used for other purposes, buri straw, kalasiao straw, and buntal straw. Generally only one variety of these straws is developed in any one place, the rest being thrown away. Buri straw is produced from the unopened buri leaf, and the hats manufactured therefrom vary in price. Kalasiao hats, otherwise known as the Pototan hat, are produced from the midrib fibre of the unopened buri leaf. In general the hats are woven in imitation of the ordinary straw hat, and in general also they are rated as rivals of the bamboo hats, being somewhat more attractive and also more expensive. Buntal straw, which is extracted from the leaf-stem of the buri palm, is the material most popular certainly in the United States. These hats are of a beautiful texture, light straw in colour, durable and stylish. They are exported in five grades, according to the usual classification, extra, and 1 to 4. The bulk of the trade is in No. 3 grade. The straw also is taken into Baliwag and there worked up in the Baliwag weave, producing by far the finest hat in the Philippines. These are the hats generally sold in the United States. Before the new tariff Act these hats went mostly to France, where they were classified and labelled, and shipped to the United States as "Bangkok," "East Indian Panama," "Italian Straw," and other products. The trade in both the bamboo hats and the buntal, or other buri hats, is of growing importance in the Philippines, where both the Bureau of Education and the Bureau of Science are aiding in every way possible in spreading knowledge as to the industry and its possibilities. Apparently there is no limit to the hat trade of the Philippines, either in its volume, particularly as regards the cheaper grade hats, or in the quality of the output, which may be classed among the highest in the world.

CORRESPONDENCE.

A B C OF HYDRODYNAMICS.

Whilst thanking your critic for his review of my "A B C of Hydrodynamics," there is one point I should like to draw attention to, as it is liable to be misunderstood. The formation of a vortex is certainly referred to *in the chapter* on a viscous fluid flowing "by obligation"; but I have been careful to say that the flow is no longer an "obligation" flow when the vortex is being formed; if it were so a vortex *could not be formed.*

Whether I shall eventually be considered to have simplified the subject or not, remains to be seen. The whole study is, at present, so full of contradictions and complexities that the attempt at simplification was, at least, worth making. Professor Unwin, in his "Treatise on Hydraulics," says: "Pure theoretical hydrodynamics has proceeded but little beyond the consideration of the action of a perfect fluid without viscosity. The conclusions are *in no case correct for actual fluids*, and in some cases are in startling contradiction with the facts of experience." As I have attempted to show, the reason for this is that the *conditions are not the same* in the two cases; given the same conditions, the results are *very similar.*

What appears complicated in the book is only what may be called the "scaffolding"—which was chiefly inserted for the benefit of the critics. Remove this scaffolding, and the remainder appears to me to be quite within the grasp of any well-educated youth of eighteen.

My whole line of argument is based on the teaching of Lord Kelvin—whose contributions to the subject are, I think, shockingly neglected.

R. DE VILLAMIL.

OBITUARY.

HENRY OPPENHEIM.—Mr. Henry Oppenheim died on the 4th inst. at his residence in Bruton Street, Mayfair. He was the son of Simon Oppenheim, a banker of Frankfort-on-the-Main, where he was born in 1835. In 1850 his father settled in London and founded the firm of S. Oppenheim and Sons, bankers, Austinfriars. On the outbreak of the Crimean War, the firm assisted the Government by providing ships for the conveyance of food for the troops, a service for

Hosted by Google

which they received the thanks of the authorities. Mr. Henry Oppenheim spent a winter in the Crimea superintending this work. After this he joined the firm of Alberti, Pinto, Oppenheim & Co., bankers, of Paris, and went to live in Cairo as the firm's representative in Egypt. The knowledge of Egyptian affairs which he there acquired enabled him to take an important part in persuading the British Government to purchase the Suez Canal shares. Mr. Oppenheim retired from business some twenty years ago. He was well known as a collector of pictures and objects of art. He joined the Royal Society of Arts in 1875.

GENERAL NOTES.

Rescue Work in Collieries. — The Home Secretary has issued a Rescue and Aid Order dealing with the formation and training of rescue brigades, and the supply and maintenance of rescue-work appliances in coal mines. The Order, which comes into force at once, will apply to all mines in which coal is worked, except in the case of such mines employing less than 100 men as may be exempted. The rescue brigades will be maintained on the following scale:—Where the number of underground employees is 250 or less, one brigade; where the employees number between 250 and 700, two brigades; where the employees number between 700 and 1,000, three brigades; where the employees number over 1,000, four brigades. Each brigade is to contain five persons, the majority of whom must be trained in first aid and hold a certificate of the St. John Ambulance or the St. Andrew's Association, and must undergo an approved course of training. Among the rules as to appliances are regulations for the provision of two suits of portable breathing apparatus for each brigade, the keeping two or more small birds or mice for testing carbon mon-oxide, one oxygen reviving apparatus, and an ambulance box, together with antiseptic solution and fresh drinking water. Similar regulations apply to the central rescue stations established to serve several collieries.

Exhibition of Silk Industry at Athens.— The official inauguration of the international exhibition of sericulture and the silk industry at Athens, under the patronage of his Majesty the King of Greece, will take place on May 19th. The exhibition, which will be held at the Zappion Palace, will remain open for two months. It will include everything connected with sericulture, as well as all machinery and processes used in the manufacture of silk. Special facilities respecting customs duty will be granted to foreign exhibitors, who will be allowed three square metres of space free of charge.

Chinese Coal Production.—While it is probable that many of the reports of unusually fine coal deposits that have long been a common feature of discussion of China's natural resources were greatly exaggerated, enough is known of some of the deposits to warrant the statement that China is well provided with fuel. At present six notable domestic sources of coal are available: one in the mining country centring about Chinwangtao, above Tientsin, known as the Kaiping mines; another in the mines in Shantung Province known as the Hungshan and Fangtse mines; a third in Honan along the Hankow-Pekin Railway, and worked by the Pekin Syndicate; another in Kiangsi-Honan border country south of Changsha, and known as the Pinghsiang mines; a fifth in the Chingching mines in Chihli Province; and a sixth in the Japanese mine at Fushun in Manchuria, and various other small fields. The output of the mines named during 1910 was 3,604,525 tons. This coal has been used in numerous local enterprises, on various Chinese railways, by Chinese naval vessels, and in Chinese Government institutions—like the mints, naval depôts, arsenals, and other Government factories—and a considerable quantity of it was exported, some to the Pacific coast of the United States.

The Italian Macaroni Industry.—The manufacture of macaroni in and near Naples is a flourishing industry, and the output is being largely increased. Several new factories have lately been erected, and with the increased demand for the product the wages of the workpeople in the various factories advanced proportionally. With a view to offset this, the large manufacturers are studying a new method of artificial drying. Many boys and girls are employed on piecework in these factories, and although labour is comparatively cheap the wages have nearly doubled in Naples during the last two years. Russian and Australian wheat seem to be largely used in the manufacture of macaroni; large quantities are imported from Taganrog. Wheat from Minnesota has been used to some extent.

Royal Society of Antiquaries of Ireland.— A Charter of Incorporation has been granted, under the Great Seal of Ireland, to the Royal Society of Antiquaries of Ireland, of which Count Plunkett, F.S.A., is President. The Society has now over a thousand members, and during the last few years has published archæological surveys of several Irish counties.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at 8 o'clock:—

May 15. — Ernest Kilburn Scott, Assoc. M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere." Sir William Ramsay, K.C.B., Nobel Laureate, F.R.S., will preside.

May 22. — Gordon Craig, "Art of the Theatre." Miss Ellen Terry will preside.

Hosted by Google

Indian Section.

Thursday afternoon, at 4.30 o'clock :—

May 16.—Neville Priestley, Managing Director, South Indian Railway, "Indian Railways." The Right Hon. Sir Edgar Speyer, Bart., will preside.

Colonial Section.

Tuesday afternoon, at 4.30 o'clock :—

May 21.—The Hon. J. G. Jenkins, "Australian Railways."

Howard Lectures.

Monday evenings, at 8 o'clock :—

Captain H. Riall Sankey, R.E. (retired), M.Inst.C.E., "Heavy Oil Engines." Four Lectures.

Syllabus.

Lecture III.—May 13.—Description of Diesel engines manufactured by various makers—Sizes in current manufacture and future possibilities—Speeds and weight for land and marine engines—Various kinds of oil available for Diesel engines; their characteristics, calorific value, and sources of supply.

Lecture IV.—May 20.—Economical results in respect of fuel and of total annual cost—Comparison of Diesel, gas and steam engines, in respect of capital cost, fuel cost, and total annual cost—Various applications to land and marine purposes —Other heavy oil engines—Semi-Diesel engines.

MEETINGS FOR THE ENSUING WEEK.

Monday, May 13...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Howard Lecture.) Captain H. Riall Sankey, "Heavy Oil Engines." (Lecture III.)

Brewing, Institute of (London Section), Criterion Restaurant, Piccadilly, W., 8 p.m. Mr. Hugh Abbot, "Some Points in the Design and Management of a Modern Bottling Store."

Journal of the Royal Society of Arts.

No. 3,104. VOL. LX.

FRIDAY, MAY 17, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

DEATH OF THE KING OF DENMARK.

H.M. King Frederick of Denmark, whose lamentable death has just been announced, was an Honorary Royal Member of the Royal Society of Arts, having accepted membership on the occasion of his visit to London in 1907.

POSTPONEMENT OF MEETING.

MR. GORDON CRAIG's absence from England will prevent his reading the paper on "The Art of the Theatre," which was announced for the 22nd inst.

NEXT WEEK.

MONDAY, MAY 20th, 8 p.m. (Howard Lecture.) CAPTAIN H. RIALL SANKEY, R.E. (retired), M.Inst.C.E., "Heavy Oil Engines." (Lecture IV.)

TUESDAY, MAY 21st, 4.30 p.m. (Colonial Section.) THE HON. J. G. JENKINS, "Australian Railways." THE RIGHT HON. LORD EMMOTT, Under-Secretary of State for the Colonies, will preside.

HOWARD LECTURE.

On Monday evening, May 13th, CAPTAIN H. RIALL SANKEY, R.E. (retired), M.Inst.C.E., delivered the third lecture of his course on "Heavy Oil Engines."

INDIAN SECTION.

Thursday afternoon, May 16th; THE RIGHT HON. SIR EDGAR SPEYER, Bart., in the chair. A paper on "Indian Railways" was read by MR. NEVILLE PRIESTLEY, Managing Director, South Indian Railway.

The paper and discussion will be published in a subsequent number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

TWENTY-FIRST ORDINARY MEETING.

Wednesday, May 15th, 1912; SIR WILLIAM RAMSAY, K.C.B., Nobel Laureate, F.R.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Abraham, Edward A. V., America-street, Georgetown, Demerara, British Guiana.

Smallbones, Robert Townsend, Loanda, Portuguese West Africa.

The following candidates were balloted for and duly elected members of the Society:—

Dubash Kader Sahib, Khan Bahadur D.K., Abiraman-Natham, Ramnad District, Madras, South India.

Gordon, Duncan Macdonald, Keng Tung, Southern Shan States, Burma.

Harris, Thomas J., Botanic Station, Bermuda.

Morris, James, jun., Westdene, Ashburton-road, Birkenhead.

Neely, David Bradley, M.D., M.P., Humboldt, Saskatchewan, Canada.

Rutton, B. N., B.A., The Mall, Lahore, India.

Seabrook, Bagster Roads, P.O. Box 96, Toronto, Canada.

Seabrook, Norman Bagster, P.O. Box 96, Toronto, Canada.

Wakefield, William Birkbeck, Wilcot, Bisley, Surrey.

The paper read was—

THE MANUFACTURE OF NITRATES FROM THE ATMOSPHERE.

By ERNEST KILBURN SCOTT, A.M.Inst.C.E., M.I.E.E.

Considering that it is only about ten years ago that the manufacture of nitrogenous products by electric power was proved to be commercially possible, the progress has been remarkable; indeed, this metallurgical development of electric power promises to be even more important than electric traction.

Hosted by Google

The two main sources of fixed nitrogen are sulphate of ammonia from gasworks, etc., and sodium nitrate from the country of Chili. Table I. gives the sulphate of ammonia produced in this country in the years 1906, 1909, and 1910. It will be noticed that the principal increases between 1906 and 1910 are—from coke ovens, 115 per cent., and from producer-gas plants, 50 per cent.; the total increase being at the rate of about 26 per cent.

TABLE I.

SULPHATE OF AMMONIA.

	1906. Tons.	1909. Tons.	1910. Tons.
Gasworks . . .	157,160	164,276	167,820
Ironworks . . .	21,284	20,228	20,139
Shaleworks . . .	48,534	57,048	59,113
Coke-ovens . . .	43,677	82,886	92,665
Producer-gas plants	18,736	24,705	27,850
Total . .	289,391	349,143	367,587

The regular exportation of nitrate of soda from Chili began in 1830, and, as will be seen from Table II., it has increased at an extremely rapid rate, and is now about two and a half million tons per annum.

TABLE II.

EXPORTS OF SODIUM NITRATE FROM CHILI.

Year.	Tons per annum.
1830	935
1850	50,000
1870	222,000
1890	1,050,000
1907	1,600,000
1908	1,970,000
1909	2,108,600
1910	2,308,200
1911	2,420,400

Against these figures the output of calcium nitrate and calcium cyanamide, which are two of the main products of the electric fixation of nitrogen processes, seem small. The important thing to notice, however, is that electrical processes are now on a sound commercial footing, and very large extensions of plant have been recently made, and are in hand.

Table III. gives particulars of the installations for the manufacture of calcium nitrate by the *direct* process of Professor Birkeland and Mr. Sam Eyde. It will be noticed that, although the first experimental plant was started only nine years ago, already the company controlling the Birkeland-Eyde patents have installations aggregating 200,000 horse-power at work, and probably by 1916 another 300,000 horse-power will be at work. All the installations mentioned in Table III. are in Norway, but installations will no doubt be erected in other countries.

TABLE III.

INSTALLATIONS OF THE NORWEGIAN HYDRO-ELECTRIC NITROGEN CO.

Year.	Horse-power.	Name of Installation.
1903	25	Experimental plant at Frognerkilens.
1903	160	Experimental plant at Ankerlökken.
1904	660	Arendal.
1905	45,000	First Notodden (Svaelgfos).
1910	15,000	Second Notodden (Lienfos).
1912	140,000	First Rjukan Installation.
1913	120,000	Second Rjukan Installation.
1914	70,000	Vamma.
1915	80,000	Matre.
1916	70,000	Tyin.

The other electrically-produced nitrogenous manure, calcium cyanamide, is made by a more *indirect* method invented by Dr. Franck and Dr. Caro, and its manufacture is not confined to Norway.

Table IV. gives the principal installations, and it is of interest to note that, although the first one on a commercial scale was erected at Piano d' Orto in Italy only eight years ago, there are works in operation, and being built, which by the end of next year will be making calcium cyanamide at the rate of over a quarter of a million tons per annum.

The Nitrogen Fertilisers Co., which owns the Odda and Alby Works, works under licence from the North-Western Cyanamide Co., which company controls this country, Norway and Sweden,

Belgium, and all the British Colonies, Protectorates and Dependencies, except Egypt and Canada. The Odda factory is now being enlarged, and at the beginning of next year will be producing 73,000 tons per annum.

In the United States the American Cyanamide Co. is about to erect a works in Alabama to manufacture 24,000 tons per annum.

BIRKELAND-EYDE FURNACE.

This furnace, invented by Professor Birkeland and Mr. Sam Eyde, of Norway, depends on the inter-action of an alternating-current arc in a constant magnetic field. The furnace, as installed at Notodden, consists of a circular sheet-steel drum about 8 ft. in diameter and 2 ft. wide, lined with refractory firebrick, and having a disc-like space in the centre, $6\frac{1}{2}$ ft. diameter and $1\frac{1}{4}$ in. wide. Air is supplied at the centre of the furnace by a Root's blower, whilst a channel round the periphery of the disc space carries off the gases and unoxidised air, as shown in Fig. 1.

Two electrodes, one of which is shown in Fig. 2, project into the centre of the furnace, and are approached to within about $\frac{1}{8}$ in. They are copper tubes, $1\frac{1}{2}$ in. diameter and $\frac{5}{8}$ in. thick, and have water circulation to keep them cool.

Surrounding the points of the electrodes there is a magnetic field of about 4,500 lines of force per square centimetre. Alternating current at 5,000 volts and fifty periods per second is sup-

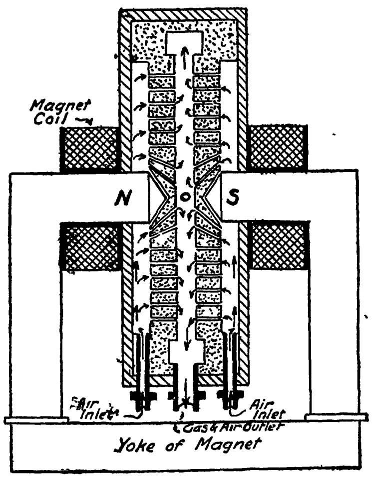

FIG. 1.

plied to the electrodes, and direct current flows round the coils to produce the magnetic field.

When an arc is struck between the electrodes, it is at once deflected in a direction perpendicular

to the lines of force, and the necessity of having alternating current applied to the electrodes will be appreciated from the fact that with direct current the arc would be deflected to one side only. As each electrode is alternatively positive and negative, the arc is projected outwards first to one side and then to the other, thus giving a disc of flame about 6 ft. in diameter. The speed at which the arc moves outward is extremely rapid, and as the formation of a new arc is practically instantaneous, it appears to the eye as a sheet of flame.

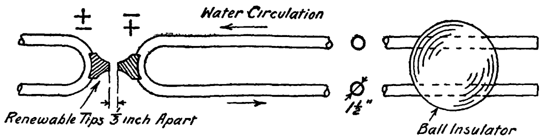

FIG. 2.

When the extremities of the arc retire along the electrodes, the arc increases in length, its resistance also increasing, until the tension is such that a new arc strikes between the points of the electrodes. The resistance of this short arc being smaller, the tension of the electrodes suddenly sinks to a point that will not sustain the long arc, which is thus extinguished. Another arc starts, and so the process goes on.

An inductive resistance is a very necessary piece of apparatus to have in series with the arc, because its self-induction automatically effects a displacement of phase according to the currents flowing, thus enabling the arc to burn steadily.

The writer assisted Mr. Howles with some experiments in fixation by nitrogen about thirteen years ago, and it was then that the necessity of having an induction coil in circuit was noted. Without it the arc could not be maintained steady, but with it the arc was quite steady. The experiment was made at Messrs. Johnson and Phillips', Old Charlton, and a transformer that happened to be handy was used for the purpose.

It should be noted that any furnace working with alternating current has necessarily a considerable phase difference. In other words, the power factor is low, and therefore, in estimating the sizes of dynamos and cables, due allowance has to be made. This, of course, raises the cost of electric energy. For ordinary power supply, a power factor of ·85 is quite usual, but with fixation of nitrogen furnaces, the power factor is only about ·6.

A curious feature of the arc flame is that it is not quite concentric. When looked at through coloured glasses the extremities of the arc appear like glowing spots upon the sides of the electrodes; on the positive electrode they are small, and fairly close together, whilst on the negative electrode they are larger and further apart. The reason for these spots appears to be that the arcs solder themselves, so to speak, to the electrodes, and the magnetic lines of force make the extremities of the arcs move along in leaps. For some reason not yet explained, the extremities of the arc cling more closely to the negative than to the positive electrode, and, therefore, the flame extends farther along the positive electrode than along the negative, as shown in Fig. 3.

When the flame is burning it emits a loud noise, from which the furnace attendant can judge of

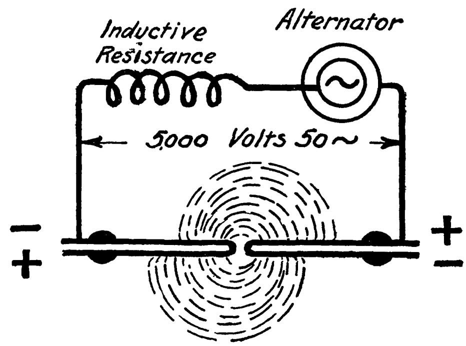

FIG. 3.

the number of arcs formed per second. The electrodes are changed and repaired every 300 hours, and the fireproof lining every fourth to sixth month. The temperature of the flame is about 3,500° C., and the temperature of the escaping gases is between 800° and 1000°.

Each of the furnaces at Notodden takes 600 kw., and the furnaces at the Rjukan works each take 3,000 kw.

SCHONHERR FURNACE.

This furnace was invented by Dr. Schonherr, of the Badische Anilin und Soda Fabrik of Germany. As installed at Christiansand, it consists of a long iron tube fixed vertically, through the centre of which an arc 16 ft. long is maintained. Alternating current at 4,200 volts, fifty periods, is used, and each furnace takes 600 horse-power. Air blown through this tube with a whirling motion

Hosted by Google

keeps the arc in the centre. The electrode at the bottom consists of an iron rod which passes through a copper water-cooled tube. The iron rod is pushed upwards, as it burns away to ferric-oxide, and fresh rods are screwed on as required, so that the process does not stop. At the top of the tube there is the water-cooler, and it is inside here that the arc ends by striking across from the centre to the side of the tube.

As will be seen from the arrows in Fig. 4 the incoming air passes through annular tubes, on each side of which there are the hot gases from the furnace. The air is thus heated to about 500° C. before it reaches the arc. After passing through the arc, where some of it is heated to about 3000° C., it reaches the water-cooler, where its temperature is then suddenly reduced. At this point there is a rapid mixing of the highly heated nitric oxide next to the arc, with the cooler air that is whirling past, and the gas becomes permanently fixed. The nitric oxide and air leave the top of the cooler at about 1200° C., and pass away to a gas flue, common to all the furnaces, where the temperature is reduced to about 850° C.

The plant at Christiansand is entirely occupied in making sodium nitrite for the production of aniline dyes, etc. Previously sodium nitrite had been made by the reduction of Chili nitrate with lead, but this method of production has now practically ceased.

The nitrite made from the nitrogen of the air is so satisfactory and so cheap compared with the old methods, that now practically the whole supply of the world, valued at £160,000, is obtained by electricity.

In order to produce it the temperature of the gases is not allowed to fall below 300° C., and this keeps the nitric oxide about equal to the nitrogen peroxide. This mixture behaves as if it were nitrogen trioxide N_2O_3, and it is absorbed completely by being brought into contact with sodium hydroxide according to the following formula—

$$NO + NO_2 + 2NaOH = H_2O + \underset{\text{sodium nitrite.}}{2NaNO}$$

Calcium Nitrate.

As carried out at Notodden, the method of making calcium nitrate is as follows:—The nitric oxide gas and air pass from each furnace into two fireproof-lined gas-collecting pipes, about 6 ft. in diameter, lined with fire-brick. These pipes convey the gas to four steam boilers, the heat given off by the gases being used to raise steam for concentrating the products and for driving the air compressors for pumping acids, soda, etc. The gases then go through tubes in the evaporating tanks, after which the temperature is down to about 250° C. The temperature is lowered still further, to 50° C., by passing it through a number of aluminium tubes over which cold water is flowing. The gas then enters the oxidation tanks, which are large vertical iron cylinders, having acid-proof linings. Here it continues to take up oxygen to form nitrogen peroxide, the percentages being now about 98 per cent. air and 2 per cent. nitrogen peroxide.

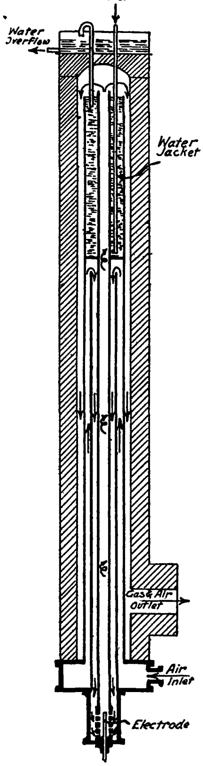

Fig. 4.

The nitrogen peroxide is brought into contact with water to form nitric acid, in two series of four towers. These towers are built of granite and are filled with broken quartz, this substance and the granite being chosen because they are not affected by acid. Each tower measures 2 metres square by 10 metres high, and it has been found that they will give an absorption of 3·3 kilograms of nitric acid per cubic metre of space per 24 hours.

The liquid trickles down through the quartz, and meeting the nitrogen peroxide gas, combines with it. The liquid moves from tower to tower in the opposite direction to the gas. Thus the fresh water enters at top of the fourth tower, it flows down through the interstices between the

pieces of quartz and falls into a granite tank. From there it is pumped by compressed air to the top of the third tower, down which it trickles into another tank, and from which it is pumped to the top of the second tower, and so on.

When the liquid reaches the bottom of the first tower it contains about 40 per cent. nitric acid.

Recently some very remarkable results have been obtained by improving the material with which these towers are filled. By using special forms of earthenware instead of quartz, the towers can be reduced in size considerably, and as the cost of the towers is usually about four times the cost of the filling material, this means much cheaper towers.

The chemical equations are as follows—

In the electric furnace from 3000° C. down to 1000° C., nitric oxide, a colourless gas, is formed—

$$N_2 + O_2 = 2NO \text{ (nitric oxide).}$$

In the oxidation chambers, etc., from 500° C. down to 50° C., the red-brown gas nitrogen peroxide is formed—

$$2NO + O_2 = 2NO_2 \text{ (nitrogen peroxide).}$$

In the four acid absorption towers the nitrogen peroxide combines with water to form nitric acid and nitrous acid—

$$2NO_2 + H_2O = HNO + HNO_2 \text{ (nitrous acid).}$$

As the nitrous acid is unstable in an aqueous solution it gives nitric acid and nitric oxide—

$$3HNO_2 + H_2O = HNO_3 + 2NO \text{ (nitric oxide).}$$

The nitric oxide then combines with more oxygen to form again nitrogen peroxide, and the above equations are repeated—

$$2NO + O_2 = 2NO_2 \text{ (nitrogen peroxide).}$$

What is left of the nitrogen peroxide and nitric oxide gases pass to the fifth tower, when they meet sodium hydroxide to form sodium nitrite—

$$NO_2 + NO + 2NaOH = H_2O + 2NaNO \text{ (sodium nitrite).}$$

The nitric acid of 40 per cent. solution is sprayed on to calcium carbonate, and the carbon dioxide gas is driven off, leaving calcium nitrate—

$$2HNO_3 + CaCO_3 = CO_2 + H_2O + Ca(NO_3)_2.$$

The solution is then pumped into solidification pans, under which cold air is circulated to accelerate cooling, and the nitrate of lime stiffens into a brittle, crystalline mass. This is broken up into lumps, which pass to ball crushing-mills, where it is reduced to a granular state. The coarse powder is then raised by an elevator into a hopper, from the bottom of which it falls into barrels which hold 2 cwt. These barrels are lined with paper to guard against damp.

The analysis of the commercial calcium nitrate, Norwegian saltpetre, or nitrate of lime as it is variously called, is given in Table V.

TABLE V.

		Per cent.
Calcium oxide	CaO	25·83
Nitrogen	N	12·47
Water	H_2O	23·83
Carbon dioxide	CO_2	0·52
Magnesium oxide	MgO	0·41
Aluminium trioxide	Al_2O_3	0·71
Residue insoluble in hydrochloric acid	—	0·51

With the Birkeland-Eyde process, one kw.-year gives 500 to 550 kilograms of nitric acid, or 853 to 938 kilograms of nitrate of lime. The latter usually contains 13 per cent. of nitrogen, which corresponds to 111 to 122 kilograms of combined nitrogen. It is *guaranteed* to contain 12¾ per cent. of nitrogen.

The best result at Notodden has been 900 kilograms of nitric acid per kw.-year measured at the arc terminals and allowing for 100 per cent. nitric acid.

The percentages of nitrogen and comparative prices of the various artificial manures are about as given in Table VI.

TABLE VI.

	Content of Nitrogen.	Price per ton.		
	Per cent.	£	s.	d.
Sulphate of Ammonia from gasworks	19·75	13	0	0
Nitrate of soda from Chili	15·50	9	15	0
Nitrate of lime made by electricity	12·75	8	10	0
Calcium cyanamide made by electricity	18·00	10	0	0

THEORY OF FIXATION.

The problem is to raise the temperature as quickly as possible to over the igniting point of nitrogen and oxygen, and then immediately to cool the fixed gas and draw it off. The temperature of the burning nitrogen and oxygen flame is lower than the igniting point by about 200° C. There must be a "hot cold zone," that is to say, a zone in which at one part the temperature is enormously high, and at another part the temperature is as low as possible.

Hosted by Google

As the electric arc gives in an easy manner the temperatures above ignition-point it is principally used. Some experimenters contend, however, that if by using a flame of carbon monoxide or a sprayed oil flame of carbo-hydrates a temperature near that of the electric arc was reached, then the results would be equally satisfactory. They point out that the ignition of nitrogen and oxygen takes place at 1800° C., and as the temperature of the electric arc is well over 2000° C., it is really much higher than is necessary.

It is not at all certain, however, that the effect is merely due to temperature. A more probable theory is that some of the oxygen is first formed into ozone, and that further on in the arc the extra atom of oxygen splits off, and being in a nascent condition readily combines with the nitrogen. In this connection it is interesting to note that Sir J. J. Thompson has demonstrated that under certain conditions N_3 does exist. Is it possible that O_3 and N_3 are first formed, and then the nascent atoms combine?

It is known that nitric acid is formed on the windings of high-tension alternators, and this is apparently due to silent discharge at normal temperature and pressure.

Mr. Cramp, whose investigations into this subject deserve to be better known, says, in a communication to the writer, that he is quite certain that ozone does enter into the problem, and that if the air charged into the furnace had ozone mixed with it, there would be an increased yield of fixed gas. A very small amount of ozone is likely to have a considerable effect; fifteen parts in one million is a high percentage. In the Central London Railway tube the percentage is only one part in a million, and yet the ozone is so powerful that its characteristic odour is quite noticeable.

The photograph, Fig. 5, shows that with alternating current the arc concentrates on one side, and the fact that ozone is a conductor may be partly or wholly responsible for this.

On several occasions it has been suggested that the yield would be higher if nitrogen and oxygen were passed through the furnace in combining proportions instead of in proportions in which they exist in air. Muthman says, however, that the proper proportions are one of nitrogen to *two* of oxygen, and his explanation is that as NO_2 is easiest to form, it is, therefore, formed first.

Several methods of fixing nitrogen have been proposed which do not depend on electric power. The principal one is due to Professor Haber, and it is of special interest just now, because the powerful German company, the Badische Anilin und Soda Fabrik is experimenting with it.

The gases nitrogen and hydrogen, in the proportions for forming into ammonia, are brought together under a pressure of 175 atmos. and they are said to combine in the presence of a catalyser such as osmium or uranium.

The Rjukanfos Installation.

The Rjukan installation is situated in Vestfjorddalen, East Telemarken. The saltpetre factories are situated at Saaheim, and the hydro-electric power-plant on the Maane River, half a kilometre away. The power-installation utilises part of the well-known "Rjukanfos," and has a working head of some 274 metres and a discharge of water of 47 cubic metres per second. The total electrical energy in the power-station is about 140,000 horse-power, divided into ten units, each of 14,450 horse-power. Each unit is, however, capable of producing 16,500 horse-power, and they are thus the largest hydro-electric units which have yet been constructed. The generators give a pressure of 10,000 volts, and the total energy is transferred to the nitrate of lime factory through a transmission line, for the most part made of bare aluminium conductors.

In the factory, some of the furnaces are of the Schonherr construction (of the Badische Anilin und Soda Fabrik), each of 1,000 kw. They are 23 feet long and require 40,000 cubic feet of air per hour. The other furnaces are of Birkeland-Eyde's construction, each of 3,000 kw. (See Figs. 6 and 7.)

The gases from the various furnaces have a temperature of about 800° C. when leaving, and they are led through brick-lined iron pipes to the coolers, which are mounted in a separate house. From there the gas goes to the absorption towers. These towers are arranged on the same system as at Notodden, namely, acid absorption for the greater part of the gases, and alkali ones for the rest.

The annual production will amount to 70,000 tons of nitrate of lime and 8,000 tons of nitrite. It will be exported in wooden kegs, exactly as at Notodden.

Regarding the question of the type of furnace, Mr. Eyde wrote on February 10th last, saying—

"The results now at hand from the trial management are not sufficient to entitle us to judge which of the two systems—the Badische or the Birkeland-Eyde system—is the most profitable one. For the present it may be declared that the proceeds by both systems very likely will turn out

Hosted by Google

to be approximately the same. As you will note, however, from the above-mentioned figures, the Birkeland-Eyde furnaces may be constructed for a considerably greater energy than the other type. by which will be produced 70,000 horse-power, of which 50,000 horse-power will be utilised for the manufacture of nitrate of lime. Including the factory at Notodden, we will thus in a short

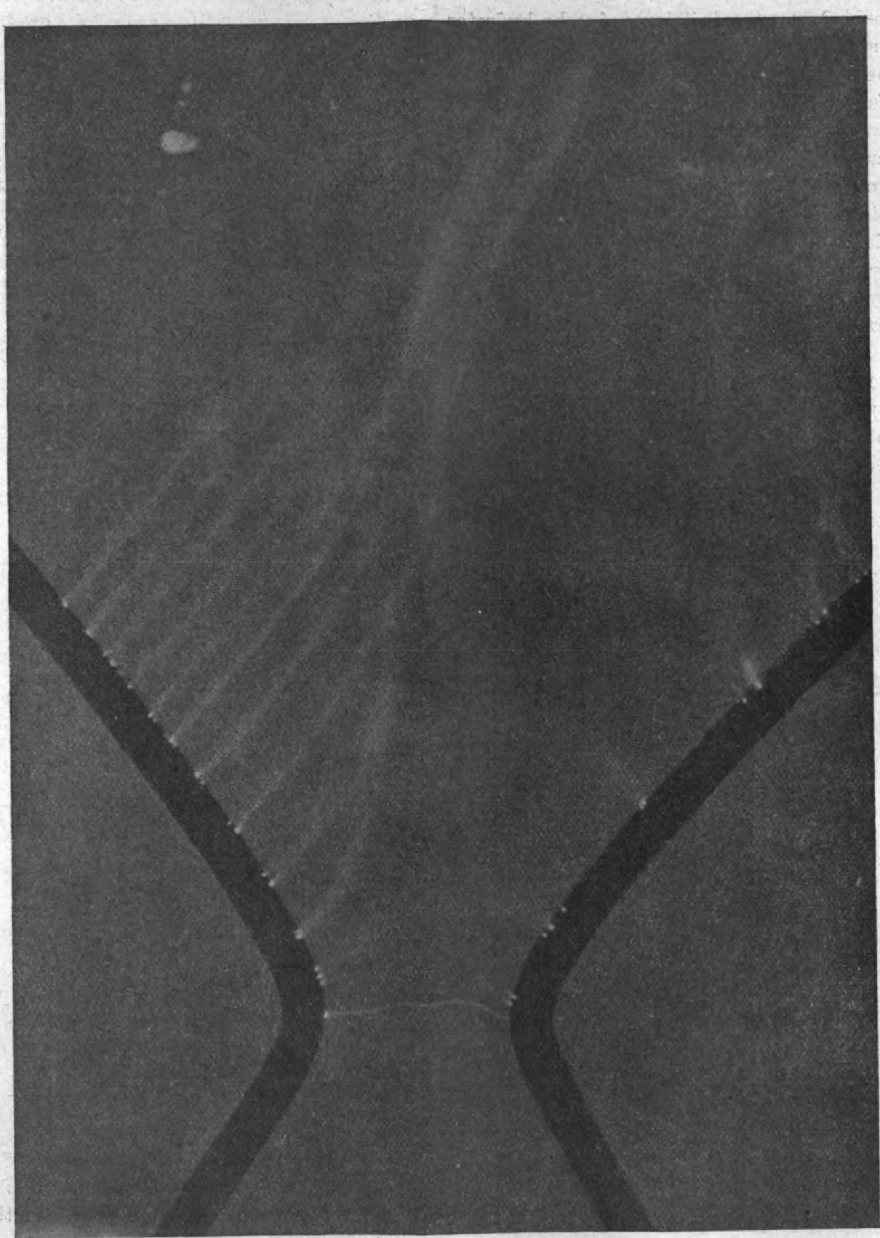

FIG. 5.—ARC FLAME, SHOWING CONCENTRATION ON ONE ELECTRODE WHEN WORKING WITH ALTERNATE CURRENT.

"A second power-plant is now under construction at Rjukan, intended for the installation of some 120,000 horse-power, which will likewise be used for the manufacture of nitrate of lime.

"Our company is further constructing a third power-installation, Vamma on the Glommen River, time utilise in all 370,000 horse-power for the manufacture of nitrate of lime."

It would appear that the Birkeland-Eyde furnace is preferred to the Schonherr because it is more compact and cheaper to build. The Schon-

View of Furnace Room showing some of the Schonherr Furnaces.

herr furnace has to be built very high in order to increase its output, and this introduces constructional difficulties, also the difficulty of keeping the arc from striking into the side of the tube.

The present plant consists of ten generator turbines of 14,450 horse-power each, five of which were constructed by J. M. Voith, of Heidenheim, five by Escher Wyss & Co., of Zurich, and one exciter turbine of 1,000 horse-power by Kräerner Brug, of Christiania. The three-phase electrical generators coupled to the Voith turbines were made by the Allmänna Svenska, of Västeras, Sweden, and those driven by the Escher Wyss turbines were supplied by Brown, Boveri & Co., of Baden. The whole of the switchboard equipment was installed by the Westinghouse Co. Table VII. gives the names of the principal contractors.

The turbines are fed by individual pipe-lines of 1,250 mm. inside diameter at the top end, and 1,000 mm. inside diameter at the bottom end. The length of each pipe is 720 metres (2,360 ft.), the upper 300 metres consist of riveted pipes, and the longer lower part for higher pressure consists of welded pipes. The riveted pipes were supplied by Frederikstad's mek. Verksted, Frederikstad, Norway, and the welded pipes by Actiengesellschaft Ferrum, Zawodzie near Kattowitz, Germany. The supply and laying out of all of the pressure pipe-lines was done under the superin-

tendence and on the responsibility of J. M. Voith.

Each turbine is designed to work with a net head of 274 metres, and a normal output of 13,000 horse-power, when running at a speed of 250 revolutions per minute. The output may be increased to 14,450 horse-power.

The main sluice valve of 1,000 mm. is fitted on a taper connecting-pipe, and the valve is operated by hydraulic pressure by means of a cylinder with piston and a distributing valve. The piston-rod carries a relay which connects it to the valve, thus preventing the latter opening or closing too quickly and ensuring perfect safety. The distributing piston is designed and dimensioned to allow the valve being opened or closed under full pressure. This valve is provided, however, with a by-pass valve 150 mm. inside diameter.

The turbines are provided with twin Pelton wheels, each of which is driven by two nozzles. In the Escher Wyss turbine the lower jet does not strike the buckets until the latter have cleared the upper jet. Each of the runner wheels, which are mounted 1,800 mm. apart on a horizontal steel shaft, consists of a separate hub of cast steel, and on the circumference of each twenty-two cast-steel buckets are fastened. The buckets are held by means of two rings which provide that there shall not be any stress on the bolts, and yet prevent the buckets getting loose.

Bearings.—The turbine shaft, which is of Siemens Martin steel, is supported by two ring-lubricated bearings of 380 mm. diameter, and its diameter is increased to 470 and 480 mm. where the runner wheels are mounted. A forged-on flange coupling transmits the whole power of the turbine to the generator shaft. In addition to lubricating rings each bearing is provided with a separate pump for the circulation of the oil, and this pump is driven

Hosted by Google

by the turbine shaft. It draws the warm oil from the bearings, passes it through a coil situated in the discharge pit of the turbine and then pumps the oil through a filter to the main shaft again. This device greatly increases the safe running. The bearings have to withstand the weight of the shaft and runners, and also the thrust due to the water jets. They are supported by a strong frame which is grouted into the foundations and held fast by anchor bolts.

Casing.—On the same side as the distributing pipe there is a strong frontal iron plate, to which the inlet bend and distributing piping are fastened. The upper half of the casing is made of wrought-iron 10 mm. thick, in two parts bolted to the foundation frame and to the frontal plate at the centre line. When the runner wheel has to be taken out for repairs, the upper part of the casing is lifted off. At the side of the casing where the shaft comes through it, deflector rings and water-splash guards prevent any water escaping from the casing. For the purpose of inspecting the buckets and nozzles a pit is provided in the foundations, by means of which it is possible to descend into the turbine chamber for that purpose.

The turbine-chamber walls are covered with iron plates from the foundation frame up to the ceiling of the tail-race, with a view to protect them from erosion as well as to prevent any leakages in the air-ducts between the turbines.

Nozzles.—The largest diameter of the water-jet when the nozzle is fully opened, is about 150 mm. In order to reduce the regulating power, the needle rod is provided with a balancing piston acting in opposite direction to two buffer springs. The latter have the tendency to close the needle. The power resulting from the closing energy of the needle and springs, and the opening energy of the piston, is so calculated that the needle is always balanced, no matter what the opening is. The turbine is regulated by simultaneously adjusting the four nozzles, which are connected to each other by means of rods and levers. A rod and lever connects the regulating shaft to the main shaft of the universal oil-pressure governor.

Guarantees.—For the speed governor and pressure regulator, as well as for the efficiency of the turbines, the following guarantees were given:—The turbines were designed to develop a maximum of 14,450 horse-power when working with a net head of 274 metres and running at 250 revolutions per minute. The efficiency was to be 76 per cent., when the quantity of water used was 5,200 litres per second. When running under the same conditions of speed and pressure, and developing normally 13,000 horse-power, the efficiency was to be 78 per cent. and the water used 4,650 litres per second. When load was suddenly thrown off to the extent of 25, 50, and 100 per cent. the variations of speed were to be limited to 3·5 per cent., 7 per cent., and 17 per cent. above normal, and the maximum increase of pressure in the pipe-line was not to exceed 15 per cent.

All these guarantees were easily maintained. In May, 1911, the pipe-lines were filled and the turbine started for the first time. A number of tests were then carried out, and about three months later the definite taking-over tests of all the turbines were made by Mr. Geheimrat Reichel, Professor of the Charlottenburg Technical School of Berlin. The output of the turbines was measured by electrical means, the quantity of water used was measured by the "Schirm Methode" in the tail-race. The highest efficiency that was attained was 82·6 per cent. with an effective turbine output of 11,000 horse-power. With nozzles fully opened the maximum effective horse-power of the turbines was about 16,000.

The maximum increase of speed was 15 per cent., whilst the increase of pressure above static head did not exceed 10 per cent.

The five Escher Wyss turbines are each coupled to three-phase generators made by Brown, Boveri & Co., of Baden.

At a power factor of ·6 each machine gives 17,000 Kva. at 11,000 volts, fifty periods per second. One of the machines gives the whole of the 17,000 Kva.

Four of the units are of the double-generator type, with a shaft common to the two. The two armatures are separated by a fireproof partition, so that if a coil of one should be burnt out the coils on the other machine are not affected.

Allowing for windage and friction, the guaranteed efficiency is 94·8 per cent. for the double generator, and 95·3 per cent. for the single generator. This is at full load, and with a power factor of ·6.

The voltage difference from full load to no load, and *vice versa*, is 1,400 volts. This may be necessary by the conditions of working the furnaces, as they are very subject to sudden changes.

The total weight of one generator is 205,000 kg. (200 tons). 92,000 kg. go to the rotating field and shaft. The armature weighs about 90,000 kg.

Hosted by Google

The armature stampings are held in position in the cast-iron armature ring by vee grooves. Cast-iron rings clamp the stampings at the ends, and these rings extend to bottom of slots. The outside diameter of the armature is 6 metres, and the inside diameter is 4·4 metres. The radial depth of the laminated structure is 21·5 cm. To permit of overhaul and repair the armature is divided on its horizontal diameter.

The magnet wheel has a cast-steel hub and arms, and the periphery of the wheel is made up of solid forged steel rings. To these rings cast-steel poles are fixed, the ends of the poles being laminated. The poles are held by dovetails and cotters.

The field poles are wound with bare annealed copper on edge, and all the poles windings are in series.

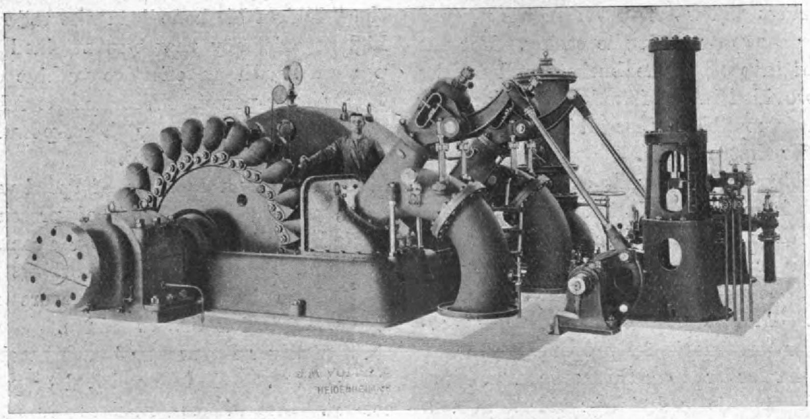

FIG. 8.—RJUKAN POWER-HOUSE.
15,000 horse-power Voith double turbine, running at 250 revolutions per minute.

The slip rings are of cast steel, and carbon brushes are used. The exciter is direct coupled and gives 130 kw. at 220 volts.

Every rotor was tested for mechanical strength by being rotated at 1·8 times the normal speed for half an hour, that is, at 450 revolutions per minute.

The bearings are supplied with oil under pressure, and the oil is cooled by water coils.

The other five turbines supplied by J. M. Voith are very similar to the above, with double-runner wheels and two nozzles to each runner. At the official tests all the guarantees were exceeded. Coupled to each of the Voith turbines is a double 8,400 Kva., 11,000 volts, 50 cycle three-phase generators made by the Allmänna Svenska Co. Each consists of two separate armatures and two revolving fields on a common shaft running on two bearings. By reason of the highly inductive load on the generators, the PF is only ·6, but with PF = unity, each machine would develop up to an individual capacity of 23,000 electrical horse-power. Each double generator weighs 250 tons.

Figs. 8 and 9 are from photographs of some of the plant used in the Rjukanfos power-house.

PAULING FURNACE.

This furnace was invented by Mr. H. Pauling, of Gelsenkirchen, Westphalia, and he took the idea from the well-known horn-break lightning arrester. As installed at Gelsenkirchen and Innsbruck it consists of two hollow iron electrodes, arranged to form a vee, which at the lowest point is about 4 cm. across, as shown in Fig.10. At this point there are two lighting knives, which can be approached to within a few millimetres, and are readily adjustable. The arc strikes across and runs up the diverging electrodes by reason of the natural convection currents, and the repelling action of its own magnetic field, but principally because of a blast of heated air from an air-duct immediately below. The arc diverges as it follows the shape of the electrodes, and it attains a length of about a yard. At each half-period of the alternating current a fresh arc forms, so that the result is the equivalent of a triangular sheet of flame.

An important feature is that the wall which divides the two parts of the furnace is hollow, and gas and air which has been through the furnace previously and been cooled, is blown through this central passage. As will be noticed from Fig. 10, this cool gas and air strikes into the top of the arc flame, and it serves to cool the gases which have just been formed. The two arcs are in series, and the furnaces

Hosted by Google

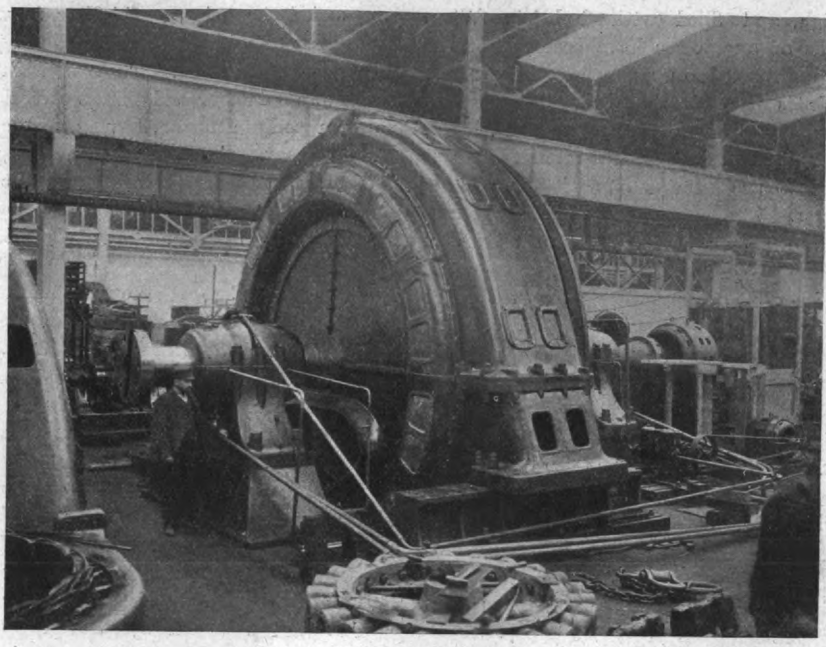

FIG. 9.—RJUKAN POWER-HOUSE.
One of the 8,400 Kva. Three-phase Alternators made by the Allmänna Svenska Electric Co.

work in sets of three, one to each phase. Each furnace, therefore, receives single-phase current at 6,000 volts, fifty periods per second.

At Gelsenkirchen there are twenty-four such furnaces, each taking 400 kw. at 4,000 volts.

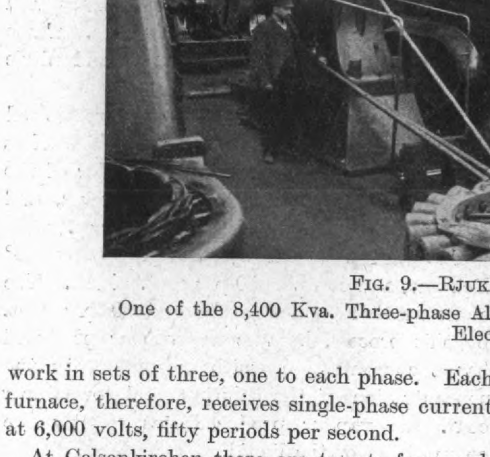

FIG. 10.

The arcs are started by means of copper starting-knives, which can be approached to within a few millimetres at the bottom, when the two horns come together. When the arc has been started, these starting-knives are withdrawn, and the larger space between the electrodes is then sufficient to let the hot air from the *tuyère* pass through freely. The starting-knives last twenty hours, whereas the main electrodes, which are of steel and water-cooled, last 200 hours.

The works of La Nitrogène Cie, at La Roche-de-Rame, Hautes Alpes, France, have nine Pauling horn-arrester furnaces of 600 horse-power each in operation, and nine more of 1,000 horse-power each are being added.

The general lay-out of the plant is shown in Fig. 11, and it will be noted that the furnaces are arranged in sets of three, one furnace to each phase.

The fresh air for the furnaces is supplied by a 250 horse-power turbo-compressor running at 3,000 revolutions, and before it gets to the furnace *tuyères* it passes through a preheater. The air travels through the furnace at 1,200 feet per second.

When the gases come from the furnaces their temperature is about 1000° C., and the nitric oxide content 1·15 to 1·5 per cent. They first pass through the preheater, and give up some of their heat to the fresh air going to the furnaces.

The gases then pass through the two cooling towers which are outside the furnace-house. Each of these towers is 16 ft. in diameter and

Hosted by Google

40 ft. high, and filled with firebrick. When the bricks of one tower have become hot the gases are switched over to the other tower. Fresh air is then drawn through the heated tower by means of the chimney (85 ft. high), and the brickwork in it is thus cooled.

The gases are sucked out of the cooling tower by a 15 horse-power fan and forced into the oxidation tower, which is built of reinforced concrete, and measures 33 ft. diameter and 75 ft. high. Here, the temperature having fallen to 600° C., oxidation to NO_2 goes on rapidly.

From the oxidation tower there are two pipe-lines, and one takes some fixed gas and air back to the furnaces, where it is passed through the central passage and comes in contact with the freshly fixed nitrogen at the top of the arcs. In this way, the fresh gas is cooled without being diluted.

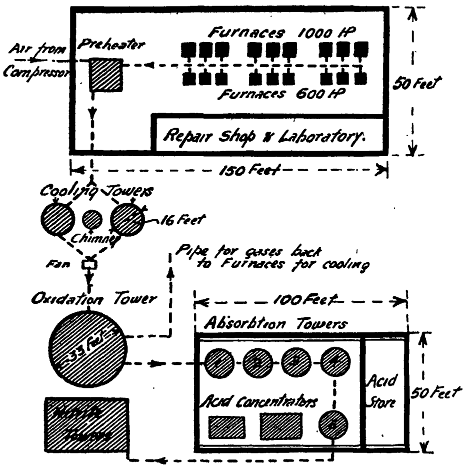

FIG. 11.—THE LAY-OUT OF THE WORKS BY LA NITROGÈNE CIE, FRANCE.

A second pipe-line of aluminium takes the remainder of the gases to the absorption towers, each of which contains 250 tons of stoneware packings. The gases pass from 1 to 5, whilst the water gradually accumulating more and more acid, flows in the opposite direction, namely, 5 to 1. *Montejus* operated by compressed air raise the solution to the top of the different towers.

The concentration of acid at bottom of No. 5 tower is about 5° Beaume; at bottom of No. 4 it is 8°; at bottom of No. 3 it is 15°; at bottom of No. 2 it is 25°; and at bottom of No. 1 it is 35°, which corresponds to about 40 per cent. of HNO_3.

The gases from No. 5 absorption tower still contain a small amount of NO and NO_2. They are passed through an acid filter, in which the last traces of acid are condensed, and then pass to the nitrite towers. These contain sodium-carbonate solution, and the gases react with it to form sodium nitrite, having a concentration of 20 per cent. This is submitted to evaporation, the hot furnaces gases being used for the purpose, and white sodium-nitrite crystals are obtained, containing 95 per cent. of nitrite and 3 per cent. of nitrate.

The nitric acid goes to the acid concentrators, in which it passes through a series of porcelain and fused quartz vessels arranged in stairway fashion. The acid is also heated by direct contact with hot gases which come from the furnace. These gases are thus charged with water and nitric acid vapour.

To condense the acid the gases are passed through a cooling coil of stoneware, which offers a large cooling surface. The remainder of the gases then pass to the oxidation tower, and mix with those coming from the furnace.

The acid obtained by the process is 36° Beaume, and contains 50 per cent. HNO_3. The concentration cannot go beyond 60 per cent. by this process, because the vapour produced has a concentration which increases with the concentration of the solution, and for 66 per cent. the vapour produced has exactly the composition of the liquid.

To obtain higher concentration other processes must be resorted to, and as high as 98 per cent. can be obtained.

Some idea of the efficiency of the plant may be obtained from the fact that Mr. Pauling guarantees 60 grams of 100 per cent. HNO_3 per kw.-hour of electrical energy, measured at the entrance of the electric transmission line into the factory; and also that the electro-chemical plant proper will cost about 120 francs (£5) per kilowatt.

The Southern Electro-Chemical Co. of Nitrolee, South Carolina, in the United States, has a 4,000 horse-power plant on the Pauling system for manufacture of calcium nitrate. Electric energy is generated in two water-power plants at Great Forks and Rocky Creek.

CALCIUM CYANAMIDE.

The discovery of calcium cyanamide came about as the result of a research by Dr. Franck and Dr. Caro, who were following on the lines of some previous work of Playfair and Bunsen. Their immediate object was to make cyanide of potassium for the recovery of gold from tailings, and they incidentally found that barium carbide

Hosted by Google

absorbed nitrogen to form barium cyanamide. By using calcium carbide they obtained a similar reaction, according to the formula—

$$CaC_2+2N=CaCN_2+C.$$

It was then found that by treating calcium cyanamide with hot water it gave off ammonia according to the equation—

$$CaCN_2+3H_2O=CaCo_3+2(NH_3),$$

and this gave rise to the idea of using it as a manure.

As carried out at the Odda Works, the calcium carbide broken into lumps is delivered to crushing machines, from which it passes to mills in which it is ground fine, the whole of these operations being effected automatically in an air-tight plant so as to prevent acetylene gas being given off. It is of interest to note that the glowing mass from the calcium carbide furnace cannot be used straight away.

The powder is then filled into electric furnaces, of which, in the first installation at Odda, there are 196, each holding 300 kg.

Fig. 12 is a rough sketch of the furnace, and it will be noticed that down the centre there is a cardboard tube to provide a space for the carbon pencil. After the carbide has been filled in, the carbon pencil is fixed in position and the lid fastened down and made air-tight.

Alternating current is now switched on, and the temperature is raised to 800° to 1000° C. The cardboard tube and certain cardboard partitions which had been placed in the furnace when the calcium carbide was run in, are burnt up, and they leave spaces which allow the nitrogen gas, which is admitted under pressure, to circulate freely. Electric current is kept on for twenty-five hours, and at the end of thirty-five hours all the nitrogen has been absorbed as shown by the meter.

At Odda this nitrogen is made by the Linde distillation process, but in one of the French factories the Claude process is used.

The 196 furnaces make about thirty tons of calcium cyanamide, containing 18 per cent. of nitrogen, per day of twenty-four hours.

When it is turned out of the furnace the cyanamide looks like black clinker. After being broken up it is fed into jaw crushers, and then goes to roulette mills, where it is ground up fine for market.

It is then packed in a paper-lined bag, which is in a jute bag. For tropical countries there are two outer jute bags.

Recently, improvements have been introduced at the Odda Works, whereby with the same amount of power and labour the output has been increased from 12,000 tons to 15,000 tons per annum.

The furnaces are now being made to hold 450 kg., instead of 300 kg. Another improvement is that the cyanamide is treated with enough atomised water to reduce free carbide to less than ½ per cent.

From the point of view of engineers in this country, the installation of A. G. Stickstoffdunger at Knapsack in Germany (see Table IV.) is perhaps the most interesting. Gas is generated from cheap brown coal, and used in gas engines to generate the electric current.

Although calcium cyanamide is mostly employed as a manure, it has other uses. For

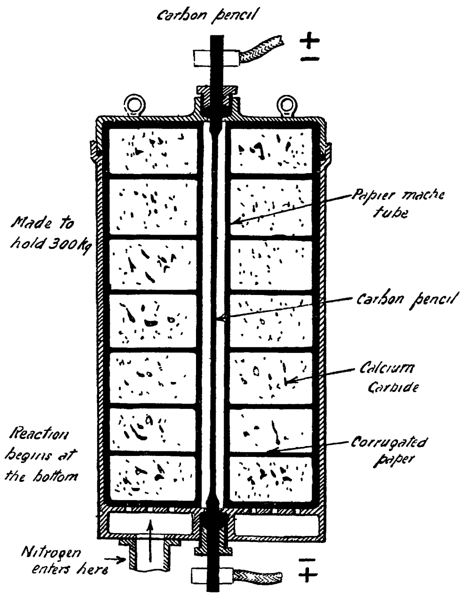

Fig. 12.—Electric Furnace for Making Calcium Cyanamide.

example, by treating with superheated steam very pure sulphate of ammonia is obtained. Also ammonium nitrate and dicyandiamide are made from it.

Explosives.

Although manures form the main outlet for the products of these electric fixation of nitrogen processes, there are other important uses.

At the Notodden Saltpetre Factory ammonium nitrate is made by bringing the nitric acid into contact with ammonia liquor from our English gasworks. The ammonia nitrate crystallises out, and when dry it contains

Hosted by Google

35 per cent. of nitrogen, and it sells in this country at about £27 a ton. It is the principal constituent of many of the explosives for mines.

Dicyandiamide, $C_2 N_4 H_4$, which is made by treating calcium cyanamide with water, when it crystallises into broad needles or prisms, is being used for mixing with explosives. It contains 66 per cent. of inert nitrogen, and is used for lowering the temperature of the explosion.

This is of importance, because ordnance powders rapidly destroy rifling in guns on account of the high temperature. The importance of this is shown by the statement made publicly in 1905 that the twelve-inch gun Mark VIII. used on fifteen British battleships could not stand more than fifty rounds full charge.

Nitric acid is of course the main constituent of gun-cotton, dynamite and smokeless powders, etc., and at the present time we are mainly dependent on overseas supplies of raw material from which to make the acid. In case of war we should undoubtedly be in a very serious position, for whereas most Continental countries have plants for the fixation of nitrogen from the air, this country does not make a single ounce.

It will be remembered that at the time of the Napoleonic wars the French had difficulty in obtaining saltpetre with which to make powder; it behoves us therefore not to be caught in the same predicament. A few rounds from a broadside of modern guns blows away into the air as much nitrogen as was used during the whole course of a war of the last century. The necessity of having factories where explosives can be made to any amount, and quite independently of raw materials from overseas, is therefore obvious. Even if the product could not at first compete in price with existing supplies, the fact that it was a necessary addition to our national assurance against war would justify the establishment of a works to fix the nitrogen of the air.

Various Government factories for the supply of munitions of war do not pay from a strictly competitive point of view, yet everyone recognises that they must be kept up.

Cost of Power.

It will be of interest to consider briefly what are the prospects as regards the manufacture of nitrogenous products in this country. The problem is, of course, mainly one of cheap power, but to make it worth while there must also be a large supply, because some of the furnaces take 1,000 kw. and upwards.

In Scotland there are several water powers waiting to be harnessed, and one has been investigated which will give 10,000 kw. for a capital expenditure in hydraulic works and electrical plant of £200,000, or £20 per kw. installed. It is estimated that electrical energy could be turned out for 35*s*. per kw.-year, after allowing 10 per cent. for interest and depreciation. The power is capable of extension.

In Norway electric energy is actually sold at about 20*s*. a kw.-year, or $\frac{20 \times 12}{8760} = \cdot 0275$ per kw.-hour, from which it would appear that the cost of installation is about £10 per kw. of plant, and a considerably lower rate than 10 per cent. is allowed for interest and depreciation. Of course the carriage of the products from Norway to this country is an item, but it would not be much more than the carriage from Scotland to the south of England.

We know that very large steam-power stations with turbo-generators can be built for about £10 a kw. of plant, because the last extensions at Manchester cost only £12 per kw., as shown by Mr. Pearce's (the chief engineer) figures.

	Per kw. installed.
Generating machinery, turbine condenser, alternator, etc.	3·75
Boilers, economisers, superheaters, steam-pipes, coal and ash conveyors, foundations, etc.	2·25
Switch-gear for generators and feeders	·55
Buildings, with accessories	5·05
	£12·05

In "Heavy Electrical Engineering," Mr. H. M. Hobart, after carefully considering all the details of a typical steam-power station, comes to the conclusion that "The complete cost of a station well designed on modern lines for an output of over 100 million kw.-hours per year need not exceed £10 per kw." With steam turbo-generating units of 25,000 kw., which are now being made, there is no reason why the cost per kw. should not come down as low as for Norwegian hydro-electric plants. Further, if instead of burning the coal in boilers it is made into gas and by-products are recovered, it seems likely that we shall be able to generate electricity as cheaply as the average for Norway.

To show what can be done by a producer-gas power plant, the following estimate by Mr.

Hosted by Google

Chorlton, of Messrs. Mather & Platt, is of interest:—

PRODUCER-GAS ENGINE POWER-STATION FOR 3,000 B.H.P.

Capital Costs:—	£
Four 1,000 B.H.P. gas engines complete; coupled to four electric generators starting air compressor; gas, air, water, and exhaust pipes; and water pumps	21,850
Buildings, engine foundations, crane and silencer	2,770
Exhaust heat boilers	1,600
Switchboard and wiring	1,500
Water tank and cooling tower	400
Capital Cost	£28,120

This is equal to £7·03 per B.H.P., or £10·545 per kw.

Running Costs, on the basis of 300, 24-hour working days per annum—	£
Oil, waste and stores	650
Repairs, rates and taxes, maintenance, insurance, etc., at ·01 pence per B.H.P. hour	900
Wages—Three shifts of one man at 40*s*. " " " one man at 35*s*.	585
Interest and depreciation at 10 per cent.	2,812
Total Running Cost per annum	£4,947

Assuming the interest and depreciation to be only 6¼ per cent., the total running cost is	£3,892
The capital cost of a Mond Producer Plant capable of giving gas for 3,000 B.H.P. is	£13,200

The Running Cost of a Mond Producer-Gas Plant is—	£
9,600 tons of shale	Nil.
900 tons of belt pickings	Nil.
1,500 tons of waste slack, at 4*s*. per ton	300
600 tons of washed slack, at 8*s*. per ton	240
Maintenance, including rates, taxes, labour (including packing), steam-power, repairs, stores, etc., at 2*s*. 6*d*. per ton	1,500
Sulphuric acid, at 35*s*. per ton	665
Interest and depreciation at 10 per cent.	1,320
Running cost per annum	£4,025

The By-Products would sell for—	£
Ammonia sulphate, at £12 per ton	4,560
Tar, at 15*s*. per ton	180
Value of gas not included	—
Credit per annum	£4,740

Leaving a net profit of
£4,740 less £4,025 = £715 per annum.

The net cost of energy, assuming interest and depreciation on station, at 10 per cent. is . . . . £4,947 less £715 = £4,232
This is equal to ·047 per B.H.P.-hour, or ·070 per kw.-hour.

The net cost of energy, assuming interest and depreciation on station, at 6¼ per cent. is . . . . £3,892 less £715 = £3,177
This is equal to ·035 per B.H.P. hour, or ·052 per kw.-hour.

This ·052 is for 300 days of 24 hours, but for the full number of hours in a year it becomes ·043*d*. per kw.-hour, or 31*s*. per kw.-year. If this can be done with 1,000 horse-power gas engines, then there is considerable hope for the future when the internal combustion prime mover is made in as large sizes and as cheaply as steam turbines.

At the present moment, so far as fuel power-stations are concerned, the position appears to be as follows.

For large prime movers of, say, 6,000 kw. and over, the steam turbine is in an unassailable position. It is true that the large gas engine has been made in units of several thousand horse-power, but on account of its slow speed and its cycle of operations the size for a given power is very large as compared with a steam turbine. Its weight and price are greater, and the cost of foundations and housing accommodation very much greater.

The gas turbine, or the gas *plus* steam turbine, would solve the space difficulty, but although much has been written on the theory, and some work has been done experimentally, this form of prime mover is still in the air.

As regards the production of steam and of gas for the above-mentioned prime movers, it must be admitted that the method of burning coal on fire-grates is less efficient than making gas from the coal and recovering the ammonia, etc. Also it is necessary to admit that there are mechanical limitations to the sizes of ordinary steam boilers as at present constructed.

On the other hand, gas-producer and engine plants cannot yet be considered altogether satisfactory, because the gas is so variable in quality. When steam is generated there is no doubt about the product.

With gas, on the other hand, there is no absolute certainty as to what its quality will be. It depends on the coal, on the condition of the apparatus, on the attention given by the workmen. If attempts are made to increase the yield of the ammonia, then the gas is likely to be poor, and if the gas is of good quality, then the by-products are apt to fall off.

A slight change in the kind of coal, and the whole of the gas apparatus has to be readjusted, and in the meantime the gas engines may have dropped to half power. On the other

Hosted by Google

hand, with a steam boiler a change in the quality of the coal makes very little difference. The steam coming away is always of the same quality, however much the fuel may vary.

The Johannesburg fiasco is still fresh in our minds, but before that there had been similar troubles in large gas-power installations in Spain and elsewhere. As compared with the steam boiler, the large gas-producer is still a faulty piece of apparatus, although it is being improved. On the other hand, the present type of boiler is not above criticism, for in size it has not kept pace with the steam turbine prime mover. For example, at the Lot's Road power-house there are eight boilers for each of the 6,000 kw. steam-turbo generators, and the cubic space occupied by the boilers is about five times that occupied by the steam-turbine set.

In the near future, steam-turbo generators will be of 20,000 kw. and over—one of larger size than that is now under construction by Parsons & Co.—and as the size of the prime mover increases, this space difficulty of the boilers also increases. It is absurd that one turbo-generator should require a dozen or so boilers to supply it with steam.

A solution of the problem is the manufacture of the coal into gas with the recovery of sulphate of ammonia, tar, and oils. Then the gas must be burnt in much more efficient boilers than those at present in use.

Hitherto gas-fired boilers have been of very low efficiency, say, somewhere about 50 per cent., but with the new method of Professor Bone and Mr. C. D. McCourt an efficiency of over 90 per cent. is attainable. The experimental plants at Leeds and at the Skininygrove Ironworks have demonstrated this beyond a doubt.

The method depends primarily on mixing gas and air together in the exact proportions for complete combustion; then forcing the mixture under pressure through tubes which are packed with pieces of refractory material. The mixture is fired at the outlet end of the tubes and strikes back to the entrance end. The flame quickly raises the refractory material to an intense heat, and complete combustion of the mixture takes place in about the first six inches from point of entry. The combustion having been completed, the remainder of the material acts as a baffle towards the burnt gases as they traverse the tubes at high velocity, causing them to impinge repeatedly on the walls of the tubes. The evaporation is so rapid that the scaling troubles met with in other types of multi-tubular boilers are completely obviated, the scale being automatically shed in thin films about $\frac{1}{30}$ in. thick as rapidly as it is formed.

The core of the material is maintained at a high temperature, but when it comes in contact with the walls of the tube it is so rapidly cooled by the transmission of heat to the water that it only attains red heat.

A boiler erected on this principle at the Skininygrove Ironworks, Yorkshire, in November last, had the following dimensions: 10 ft. diameter and 4 ft. from back to front, 110 tubes, of 3 in. internal diameter packed with fragments of firebrick. The gas supplied from Otto Hilgenstock coke-ovens is mixed with little more than its correct proportion of air, and the mixture is forced into the tubes at about 2 in. water-gauge pressure. The evaporation is 5,500 lbs. of water per hour, and before being taken over by the Skininygrove Ironworks Co., it was run for a month day and night.

When one considers that a well-known boiler, to evaporate 3,140 lbs. of water per hour, occupies about 23 ft. by 13 ft. by 15 ft., it will be seen how great a saving there is in space.

On February 21st, 1912, Mr. Ernest Bury, M.Sc., wrote that the

"Boncourt boiler which was started up on November 7th last, has continued to work very satisfactorily; its working is almost entirely automatic, and is included in the routine work of the exhaust-engine men, who have eleven running machines under their control.

"The boiler has been off for inspection of the tubes, which proved to be clean and free from scale, a fact which I attribute to highly rapid ebullition. During the length of time the boiler has been at work, we have had no trouble with priming; at all times the steam having been perfectly dry.

"The average temperature of the waste gases leaving the plant has been 78°–80° C., which is ample proof of the boiler's efficiency.

"Generally, I consider that the boiler has come up to expectations. It is certainly the cheapest method of raising steam which has yet been devised."

Sir William Ramsay's Proposal.

The proposal to burn the coal *in situ* and bring the gases to the surface, when the ammonia, etc., can be extracted and the gases utilised for power, has attracted a good deal of attention.

That the coal when fired will keep alight for years and give off useful gases is quite well known. In New South Wales there is a seam of coal which has been alight for many years, but it is near the surface, and the air can get

Hosted by Google

down fairly easily. With the deep seams of this country special provision would have to be made.

For burning out thin seams in old collieries the scheme is very attractive, because shafts already exist, and there are many seams which are too thin to work in the ordinary way. The limit for economical working appears to be 12 ins. to 15 ins. Lidgett Colliery, near Barnsley, worked an 18-in. thick seam for many years, but it closed this year. There are, however, several other collieries in Yorkshire working seams in the neighbourhood of 15 ins. thick; one colliery near Wakefield having a seam 16 ins. thick. In these very thin seams the men have to go along the gate roads laid on low trucks, face downwards, and they propel themselves forward with their toes. It really is surprising that men can be found to undertake such work, and no doubt, as time goes on, it will become more and more difficult to get men for this work. Of course, these very thin seams can only be worked when the coal is of very good quality and prices are good. We may take it, therefore, that Sir William Ramsay's suggestion has plenty of scope in the seams of under 15 ins. thick, of which there are many.

There are also many pits which contain the particular coal known as "cannel," which is specially suitable for making gas. A case in point is the Leen Valley coalfield of Nottinghamshire, where the seam known as "tophard" will be worked out in twenty years. Now the top part of this seam consists of inferior cannel coal, and since the gas companies took to producing low illuminating gas and enriching it with other materials than cannel, practically none of it has been raised to the surface.

In the five collieries of the Leen Valley, namely Hucknall, Lenby, Annesley, Bestwood, and Newstead, there are millions of tons of cannel coal, to say nothing of slack left from the seam of top hard coal and a great deal of timber.

The shafts are already down and roads made, and supposing that lower seams prove unremunerative, then all this cannel coal could be burnt out for a supply of gas. There are certainly 15,000 acres of such coal within 120 miles of London.

Equalising the Load.

The problem of utilising the electric energy of power-stations at periods when such stations are working on low loads is beginning to attract the attention it deserves. The ideal for any power-house is to secure a load of 100 per cent. load factor, and there is no doubt that if greater efforts were made in this direction the price of power would come down considerably.

The valleys have been filled in, to some extent, by power and traction loads, but as these also have to be supplied at the same time as lighting the result was not as beneficial as it was thought it would be.

Now an electro-chemical or metallurgical proposition is quite different, because such plants can often be shut down during the twenty-four hours for an hour or two, the load can therefore be adjusted to just fill up the valleys.

The Yorkshire Electric Power Co. was early in the field with this method of working, in connection with the carbide of calcium plant at Thornhill. It is of interest to note, by the way, that this power company is supplying electric energy to fifteen collieries.

At Legnano a nitric acid plant of 4,000 kw. has been at work for some time past, which operates only during the night and certain hours of the day, when power is supplied at a cheap rate from the hydro-electric station by the Società Lombarda per Distribuzione dell' Energia Elettrica. Current is supplied by the power company at 50,000 volts, and, although the price charged does not transpire, it is evidently at a figure that enables the process to pay, because an extension of 9,000 kw. is being installed.

A proposal that is being seriously considered at the present time in India is the utilisation of the water-power from an irrigation dam for the manufacture of manure. Owing to irrigation requirements, electric energy will only be available for nine months in the year, but that will not militate against the manufacture, as nitrogen fixation furnaces can be shut down and started up again at any time. The use of water from irrigation dams to manufacture manures for the farmers gives a double benefit, and there are many places in the Colonies, and in Australia in particular, where such a scheme is feasible.

The Indian scheme is for 30,000 horse-power, and it is said that 37,000 tons of calcium cyanamide, containing 18 to 20 per cent. nitrogen, can be produced in the nine months with that power.

Conclusion.

We, as a nation, are sadly behind Continental countries in the exploitation of the electro-metallurgical field. It is all very well to start manufacturing "when the business has steadied down," but generally by that time the best has been taken out of it. The processes become

Hosted by Google

ringed round with patent rights, for naturally the master patents go to those who first commence to exploit a process commercially.

In the fixation of nitrogen nearly all the pioneer work of the laboratory stage was done in this country by Dr. Priestly, Lord Rayleigh, Sir Wm. Crookes, McDougall and Howles, etc. The actual exploitation on a commercial scale has, however, been effected by a few Norwegian and German engineers, and the centre of gravity of electrical enterprise at the present time appears to be in Scandinavia.

It is high time for the engineers and business men of this country to go into the matter to see why it is we are lagging behind, and especially to look into the question of cheap power supply. Above everything else, a progressive industrial country wants cheap power, whilst at the same time conserving its resources. We have carried municipal trading in electricity further than other countries, but have very little to show for it. There are a number of municipal plants, run by committees of amateurs who know nothing about the business, and who frequently have not the sense to pay decent salaries to engineers who could tell them. What chance have such plants of generating cheaply?

The big things of electrical engineering are now being passed over because we lack cheap power, and this is especially the case in electro-metallurgy. Within the next generation or so all previous work in electricity will look small against it, for the future is certainly for the electro-chemist and electro-metallurgist.

DISCUSSION.

The Chairman (Sir William Ramsay) said that Mr. Kilburn Scott had given a very complete survey of the field covered by his subject, and the paper provided one of the best accounts available at the present moment. As the author had said, the process began with Dr. Priestley, and, later on, with Cavendish. It might be interesting to refer to the amount of work which Cavendish expended in turning the handle of his electrical machine; he and his assistant turned it for three weeks—the speaker could not say with what pauses—in making a few grains of nitrate, presumably of sodium. Turned into kilowatts, the result would be very low. On the question of the original patents, it did not appear to be generally known that Professor P. Guye, of Switzerland, was the original patentee. The whole problem turned upon the sudden cooling of the hot gas, and M. Guye patented that idea and also the appliances by which it could be carried out, the gas passing out of a confined space into a wide space. M. Guye took out his patent about 1898, before anyone had troubled about the matter, and therefore, even if still valid, they could now only have a short time to run. Again, it was M. Guye's furnace which was now described as Schonherr's, the latter being simply an imitation. Sir William had seen M. Guye's furnace running in Switzerland many years ago, and he had difficulty in understanding why Dr. Schonherr was allowed a patent, unless upon the ground of small modifications. Another point upon which he would comment was the difficulty in relation to deliquescence. Originally the nitrate of calcium could not be handled, as it turned wet when exposed to the air. It was Dr. Messel who suggested the making of basic calcium nitrate, and he had made a free gift of the suggestion to the Norwegian Company. Without such aid the company would have had trouble with their manure; it would have been utterly unworkable, as it absorbed moisture as quickly as chloride of calcium itself. Some years ago, at the Society of Chemical Industry, Professor Guye had spoken of the advantage of bringing together the two methods of fixing nitrogen, namely, the direct method of Birkeland and Eyde and the indirect method of Franck and Caro. The method used by Linde to fractionate liquid air gave pure nitrogen, and at the same time it also gave oxygen. Conversely, the combination of nitrogen and oxygen by the other processes gave a much better yield if the amount of oxygen were increased. The improvement in the yield, he believed, amounted to 25 per cent. It would, however, scarcely pay to use liquid-air plant to get pure oxygen for the purpose of mixing it with the ordinary air so as to intensify the amount of oxygen, the cost of liquefaction covering the gain. But if the two processes were proceeding simultaneously, one requiring pure nitrogen for the Caro-Franck process, and the other requiring oxygen which could be mixed with air so as to enrich it, Sir William believed that much better results would be obtained on both sides. With regard to Mr. Scott's estimates of power, he was unaware that power could be obtained at 20*s.* a kw.-year; he would have expected it to be rather higher. He would put forward the following suggestion with regard to the matter of raising steam. By pumping a mixture of gas and air into a sort of blow-pipe inside the boiler, and allowing the gas to mix with the steam of the boiler, practically all the heat of the gas could be utilised in generating steam, except so far as radiation was concerned. He had desired to deal with this proposal on a large scale, but opportunity was lacking, in addition to which it would probably cost some £20,000 to bring it into practical working. He was not sufficient of an engineer to say if the plan would be a great disadvantage in the case of the turbine.

Mr. A. A. Campbell Swinton did not know that it was altogether understood how it was that the gas turbine had not come to the fore. Turbines, of whatever kind, were essentially machines in which

Hosted by Google

the actuating fluid had to come into intimate contact with the vanes and walls of the apparatus. For a gas turbine to have any advantage, the gas must be used at the full temperature obtained with combustion, a temperature considerably above that of red-hot iron. It was essential, therefore, to find a material (for a gas turbine) which would run at red-heat. No such material existed, however; machines of steel or iron would go to pieces in a very brief time. The alternative was to dilute the gas with, say, steam or water to reduce the temperatures. The temperature had to be reduced to that available with ordinary superheated steam, with resulting loss of the entire thermo-dynamic advantage of gas. Further, in order to get the full effect of burning gas with air, compression was necessary, and all methods of compressing were very inefficient. There seemed no immediate prospect of a gas turbine, and accordingly it was very important to get the best effect in the way of firing boilers by means of gas, so that the by-products from the coal could be obtained before burning it. The speaker had seen Professor Bone's boiler—the smaller size—in which steam was raised from cold water to 150 lbs. in a few minutes. The bottom of the boiler was cold, and could be touched. He understood the efficiency of this boiler was extraordinary, and that the total loss of heat was about 7 per cent. or 10 per cent., which included the power required for blowing. At the Skininygrove works it was being employed on a large scale. Dealing with the Chairman's suggestion of burning gas in the water, he would say that a vacuum was essential. An air pump large enough to deal with the products that would not condense would have to be very large; otherwise proper efficiency could not be obtained. As a matter of fact, steam turbines were much more effective at the vacuum end than at the high-pressure end. The speaker had devoted considerable attention to water-power in Scotland. There were several fine sources of power which might be harnessed, not comparable to those of Norway, but ranging between 10,000 and 20,000 horse-power kw. Unfortunately, the small scale of them made it difficult to utilise them for the fixation of nitrogen.

Mr. Walter F. Reid referred to the question of greatest importance, namely, that of cheap power. In this connection he was not sure that in this country a power could not be obtained which, from the point of view of cheapness, would compare with the power obtainable in Norway. He alluded also to the possession in this country of factories which could produce the absolutely essential material for a national defence. Some time ago, as a member of a deputation, he had waited upon Mr. Lloyd George, and had argued the importance of this country being able, independently of foreign sources of supply, to produce the nitric acid necessary for its explosives. Large quantities of this material were being made electrically in various parts of the world, and the matter was urgent from the point of view of economy and national independence; we ought not to be exposed to the liability of the supplies being cut off in case of war. The French Revolution furnished an instance. The British ships cut off the supply of saltpetre from India, and but for a chemist who stimulated the manufacture of this material from stable refuse and all kinds of organic materials, France would have been wholly deprived of saltpetre. In connection with the use of calcium nitrate and calcium cyanamide as manures, it was well to remember that nitrifying bacteria could be propagated in the soil, and the organisms which preyed upon them could be destroyed by heat. The speaker doubted if fixation of artificial manures could compete with this method. At present, however, available methods must be utilised, and it had been shown that nitrogen from the atmosphere was a marketable product and could compete with nitrate of soda. Coal was the most important source of energy in this country, and he thought the suggestion made by the Chairman at the Smoke Abatement Exhibition might be a way out of present difficulties. The production of gas in the mine itself, and its utilisation on the spot in fixing nitrogen from the air should enable us to compete on fairly even terms with material which had to be imported from a considerable distance. The plan seemed feasible, and offered a possible investment for capital now going abroad. While agreeing with the author as to the failure of certain large gas-engine plants, he did not feel that this excluded any prospect of getting larger gas engines in the future. He did not, however, see any necessity to build them so large; electric energy could be concentrated in a number of small units, which could be run economically with cheap gas. With regard to recovery of waste products from gas producers, it should not be forgotten that in fixing atmospheric nitrogen on a large scale the value of such waste products would be diminished, and the price of sulphate of ammonia would fall. In discussing large factories, the speaker alluded to the curious fact that the nitrate of soda in the lyes was a waste product; originally this nitrate was the source of the whole of the nitric acid. He rather believed that there was considerable waste going on in these factories, due to the predominance of the engineer and disregard of the chemist, who could better work out certain details. The speaker had had occasion to investigate one of the processes that had been mentioned, and had found that the gases were diluted to as much as 100 per cent., whereas one of the essential requirements of the apparatus was to keep the gases as concentrated as possible. Leakage over the furnace part of the apparatus, resulted in the air being so diluted that the actual yield was only one third of the amount of nitrous gases in the furnace immediately above the flame. Another important source of waste was the escaping gases

Hosted by Google

from the condensation towers and chambers; the fumes that escaped formed a considerable percentage of the whole, and the chemist might be of good service in pointing out methods of avoiding such escape.

Professor A. W. Crossley, F.R.S., referred to the paper read by Lord Rayleigh in 1906, before the Chemical Society, on the union of nitrogen and oxygen by means of the electric flame; an experiment which was made use of by his lordship and the Chairman in their discovery of argon. Few present on that occasion would have realised that the true expression of its utility would be found in works like those at Notodden and Rjukan. It was necessary to visit the latter place to appreciate what was going on; to be actually in the power-house and factory to realise the grand scale on which it was being carried out. Anyone having that experience would be impressed by the great skill and scientific ability of those who had made a success of the process. Enormous engineering difficulties had been overcome; pushed aside as if they were of no moment. Mr. Reid had mentioned sodium nitrate as a waste product. That was not quite exact; the actual waste product was an approximately equal mixture of sodium nitrate and sodium nitrite. It was, however, unnecessary to manufacture any more sodium nitrite than was desired; the waste product might be calcium nitrate if it were thought fit. In the case of the Birkeland-Eyde process he had been told that the larger the furnace the better the yield.

Mr. Ernest Kilburn Scott, in replying to the discussion, stated that the Nitrogen Fertiliser Company were using the Linde process for making nitrogen, but, under the licence they could not sell the by-product oxygen. The Birkeland-Eyde people wanted the oxygen, and it certainly looked as if a combination of the two processes might, as suggested by the Chairman, prove an advantage. It was a distinct advantage to mix the two manures. The calcium nitrate was certainly hygroscopic, and if sown with the hand it made the hand very wet. Tests made, on a very limited scale, by the speaker, did show that the use of a combination of the two manures was better than employing either one alone. Several years of experimental work were necessary for an adequate test, but for applying, he had found it easier to sow a mixture of the manures than to sow either separately. With regard to raising steam by burning the gas in the water, this was, he understood, being tried in Germany. It would, as Mr. Campbell Swinton had said, be necessary to have large air pumps to get rid of the gaseous products. The steam turbine would not work efficiently without condensers, a fact demonstrated by Sir C. Parsons in 1892; turbines were a great success now, because of the application of special condensers. There were many incidental drawbacks to the employment of Scottish water-powers, arising from the opposition of those who wish to conserve the waters. No doubt power-stations might at first impair scenic effects, but in a few years nature covered up what was unsightly. With regard to the efficiency of Professor Bone's boiler, he had been assured that this efficiency was 90 per cent., and, on personal investigation, he found nothing wrong with the figures. In the case of an ordinary gas-fired boiler, such as used in steelworks, the efficiency was seldom more than 50 per cent., while for steam boilers in power-houses it was rarely more than 80 per cent. In the Boncourt boiler, it seemed that the swift ebullition of the water did not permit the formation of scale, so that less pure water could be used; with such violent ebullition any scale reaching $\frac{1}{30}$ inch fell to the bottom. The boiler at Skininygrove was one of a large number, and received no special attention. He agreed with Mr. Reid, that the chemist was a very necessary functionary in a works. That was shown clearly in the case of the absorption towers. Here the engineers' idea had been to fill them with pieces of quartz, letting the water trickle down between the pieces. The chemist rejected this practice, and directed the building-up of proper tiles or bricks, which allowed the water and gas to go only in certain directions. In the result the towers were cut down to half their former size. He was glad Dr. Crossley had confirmed his remarks on Rjukan. Large stations could be built in this country, and in this relation the speaker referred to the sixty odd power-stations in London, whereas, in his view, there should be only three or four, electrically linked together. There was no necessity for the power-stations to be in London at all, seeing that the distance of transmission was not of importance. Many large industrial towns in the United States, Canada, and on the Continent, drew their power from sources 50 miles distant. The time was ripe for the construction of large stations. The power-stations of the future would be at the coalfields. They would utilise the coal properly by making it into gas and recovering the by-products, and the generating units would be of 25,000 kw. or so. In the United States sets of that size were being used, whereas the largest sets in this country at the present time were only 6,000 kw. The power companies should be encouraged in every possible way to build, for large power-stations were absolutely essential to the supply of cheap power; and by the expression cheap power one meant rates that are comparable to those charged in Norway. Up to now the power companies had been hindered in every possible way, and particularly by those who encouraged the universal trading idea. About 75 per cent. of the municipal plants in this country want turning into sub-stations taking power in bulk from large power-stations, each many times larger than our present largest. In many of the Colonies—he could instance Australia, India, etc.—the future of the country was dependent upon water service, and large dams had been erected to conserve the water for the land. One dam in Australia was 180 feet high. These dams could develop a good deal of power, and a suitable use for this power

Hosted by Google

would be in the manufacture of manures for farmers, who would also be using the water for irrigation. Virgin soil would grow crops for a few years because of its stores of nitrogen, but then, as in the United States and other parts, the nitrogen would be exhausted, and fresh supplies would have to be placed on the land. There was a proposal in India, at the present time, to harness water-power to the extent of 30,000 horse-power, and manufacture manures for nine months in the year, with water that would be also employed in irrigation. The furnaces which he had described could be shut down at any time for a few hours or for a longer period.

On the motion of the CHAIRMAN, a vote of thanks was accorded to Mr. Ernest Kilburn Scott, and the meeting terminated.

EMPIRE NOTES.

Imperial Exhibition.—Arrangements for holding an Imperial Exhibition in London in 1915 are in progress. A general committee of 120 members has been formed, by whom an advisory committee has been appointed, with Sir Peter Stewart-Bam as chairman, and Messrs. A. Cecil Beck, M.P., and P. T. Hannon as hon. secretaries. Lord Strathcona has agreed to act as president. The objects of the exhibition are indicated in the title. It is hoped that by it the resources of the Empire will be demonstrated to visitors and to commercial men from all parts of the world, to the advantage of closer commercial relations with the various parts of the Empire, and, generally, to the advantage of British trade. The site of the exhibition has not yet been determined upon. Offices have been taken in St. Stephen's House, Westminster.

Overseas Timber Industry and Afforestation.—In all parts of Canada the timber (lumber) industry is in active operation. In the west, many new lumber yards have been opened, while in the east, the trade, which was better in 1911 that in the previous year, is likely to be still better in 1912. So many building contracts throughout the Dominion have been let, that an unusually large demand has been made for all kinds of building timbers. In 1911 the total cut in British Columbia was 1,100 million feet, as compared with 936 million feet in 1910. But this year that amount is likely to be exceeded. An increased demand from the United States for laths and shingles has stimulated the industry in New Brunswick, so that a number of small mills are now in active operation in that province. Similarly in Australia the demand for building and other timbers is rapidly increasing. This demand has given an impetus in the Commonwealth to the question of forest preservation and afforestation. In Western Australia, for example, the Government have decided to increase the reserves of forest areas. So rich has the south-western division of that State been in hard woods, Jarrah and Karri particularly, that little effort has been made to regulate the work of timber-cutters. But it is felt that the time has come to give this important question the attention it has so long deserved, and by means of revised regulations, the increase of forest reserves, and re-afforestation, to conserve the industry as far as possible. Efforts are also being made to encourage the growth of soft woods, for which purpose an area of 4,700 acres has been selected in the Albany district for a pine plantation. In South Africa, also, the subject of forming plantations, in the Transvaal and Natal, is under consideration; while in the districts where the climate is dry, but the soil is deep and porous, it is suggested that test plantations should be made, where some of the drought-resisting gums of Australia may, on experiment, be found successful.

The Great Lakes and Waterways of Canada and the States.—An old dispute as to the use and control of the Great Lakes between Canada and the United States has been revived by the action taken by the Sanitary Board of Chicago. That important and powerful body has obtained sanction to deepen the drainage canal between Lake Michigan and the Illinois River in order to provide a waterway from the Great Lakes to the Gulf of Mexico, viâ the Illinois and Mississippi Rivers. For this purpose the United States Government have authorised the diversion of 10,000 cubic feet of water per second from Lake Michigan. Should this be carried into effect, the Canadian Government have been informed by their engineers, the main level of Lakes Huron and Michigan will be lowered six inches, Lake Erie five inches, and Lake Ontario four inches, to the serious disadvantage of the lake-shore business carried on by the Dominion. Enormous expenditure would have to be incurred to restore the depths of harbours and to maintain the canal system. The Sault Sainte Marie and Welland Canals, by which the great bulk of the wheat from the west is conveyed to the coast, and the depth of which—at any rate, in the case of the latter—it is proposed to increase, in order to allow for the transit of deeper vessels, would be seriously injured were the contemplated lowering of lake levels to be made. The importance of this canal trade may be realised by the fact that the total tonnage of vessels passing through the Sault Canal in a brief seasonal year is about four times as large as that of the Suez Canal in the twelve months of the year. Besides this, the proposal to increase the carrying power of the Welland Canal, for which purpose arrangements are now in progress by the Canadian Government, who propose to spend ten millions sterling on the undertaking, would, it is alleged, be rendered abortive.

Canadian Trade Returns.—The trade returns for the year ending February 29th of this year show that Canada is more than maintaining the progress she has made in recent years. Her total trade during the time under review is valued at 847 million dollars (£174,043,000), which represents an

Hosted by Google

increase of 93½ million dollars (£19,212,330) over the previous year. Of this large amount, the value of the trade done with the United States was 453 million dollars (£93,082,200), of which 348½ million dollars (£71,000,000) was for imports. The increase of the latter over the previous year was nearly 70 million dollars (£14,583,300). The trade with this country amounted to just over 260½ million dollars (£53,549,439), of which 115,404,027 dollars (£23,718,000) represented imports, the increase of the latter over the previous year only amounting to about 5½ million dollars (£1,255,000). The comparison of the volume of trade done by Canada with the United States and with the Mother Country suggests some cause for reflection. It is true, the proximity of Canada and the States must result in an ever-increasing volume of trade between the two countries, as the growing prosperity of both demands new and reciprocal markets, but it may be possible for our manufacturers to obtain a larger share in the increase of Canadian business if only they will study local conditions and requirements, and will adopt more progressive means of making their products known throughout the Dominion. The recent appointment of Mr. Grigg, the former British Trade Commissioner in Canada, as head of the Dominion Government Department of Trade and Commerce, at Ottawa, should be of service towards this end.

Sugar-growing in Queensland.—As an illustration of the truth that "the old order changeth, giving place to the new," the conditions under which sugar is grown in Queensland may well be cited. It is not more than twenty years ago, if so long, that the big plantation system was predominant in the sugar-growing districts of that State. Now the leading feature of that industry is the number of small white cane-growers engaged in it, many of whom send their cane to co-operative central mills of which they are themselves joint proprietors. Sugar-cane growing has therefore passed out of the hands of the few rich planters and companies, and has become a democratic industry, worked by white labour, to the advantage, it would appear, of a large number of small holders, and also of the State. The adoption of this system has been greatly promoted by the Government, who have established central mills in suitable neighbourhoods, to which the local planter may send his cane to be crushed. So successful has this system proved, that in some of the West Indian Islands the example of Queensland is being followed, and efforts are being made to create a class of small cane-growers. The advocates of small holdings in this country may find some encouragement, by studying the conditions under which the sugar growers of Queensland are now able to carry on their work.

Native Labour in the Transvaal.—The Transvaal Chamber of Mines, in its annual report, states that the number of native labourers employed by mining and other companies on December 31st, 1911, was 195,850, as compared with 197,309 on th[illegible] same date in 1911. The numbers employed by [illegible]e Railway Police and Public Works were 14,257 [illegible] 1911, and 16,553 in 1910. Each case shows [illegible] reduction, which, though small, indicates th[illegible] increasing difficulty of obtaining native labour, especially in view of the growing demands of the mines and other industries. Amongst other causes of this shortage of labour, the Report d[illegible] attention to the competition of the Railway [illegible]ent in the Transkei for the construction o[illegible] [illegible]lway lines. The report states that "the mos[illegible] [illegible]s aspect of the labour supply of the gold [illegible] the ever-increasing cost of recruiting, and [illegible] in[illegible]ease in the wages of natives. The inevitab[illegible] [illegible]nclu[illegible]on to be drawn from the foregoing fac[illegible] [illegible] that, notwithstanding persistent efforts in [illegible] areas [illegible]t present available for recruiting purposes, the supply of natives offering themselves for work i[illegible] [illegible]dequate to meet the demand for unskilled lab[illegible]." The report concludes its reference to this subject by the important statement that the Union Government are "fully alive to the seriousness of the position, and may devise means of importing European labour for agricultural and domestic purposes, in order to set free those natives who are so employed at present for work in the mines." This may be a "counsel of perf[illegible]tion," but it indicates a possible change in t[illegible] policy of the Government of South Afr[illegible] [illegible] subject of immigration, of which th[illegible] [illegible]rested in that question will not fail t[illegible] [illegible]e no[illegible].

Delhi Town-Planning and Improvements.—It is reported that a Town-Planning Bill for Delhi will be prepared by the Indian Government and submitted to the Legislative Council in S[illegible]ptember. But already the municipal government of that city have started some important improvements. The work on the Bela, which was commenced before the holding of the Durbar, is now approaching completion. A further great improvement has been effected by turning the dense jungle lying between Tripolia Bridge and Osmanpur Road, which was full of insanitary depressions, into a fine, open, park-like expanse. The Quadsia Creek has also been filled up, and a new graded watercourse constructed. The city ditch is to be extended from the point at which it empties into the new watercourse across the Bela, and sullage water is to be utilised for irrigating an area of fifty acres which will be cropped. The course will then be used as a stored water channel. The old "Wanchaki" channel at the Nigham Budh Gate has been arched over, and the "Jhit" is being rapidly filled up, reclaiming a large area of land.

OBITUARY.

Sir John Joseph Grinlinton.—Sir John Grinlinton, who had been a member of th[illegible] [illegible]ciety since 1892, died on the 12th inst. in his [illegible] fifth

year. He served as a private soldier in the Crimea and gained a commission by his services. He had previously been employed on the Ordnance Survey, and was made an assistant engineer at the siege of Sevastopol. In 1857 he was appointed Assistant Surveyor-General of Ceylon. He soon quitted the Service and held various official posts in the island. Eventually, about 1872, he resigned the public service and devoted himself to business matters, in which he was very successful. Later on he became a member of the Legislative Council, and held other official appointments. He was Commissioner for Ceylon at the Chicago Exhibition in 1893, and in that capacity he rendered very valuable services to the interests of the island, services which were acknowledged by the honour of knighthood in 1894. At the Exhibition he made himself very popular, and was much esteemed by his colleagues among the foreign representatives and the American official staff. He went back to Ceylon for a few years, but in 1898 he came over to England, and has since resided in this country.

GENERAL NOTES.

EXHIBITION OF PICTURES BY THE "MOORE" FAMILY, OF YORK.—The Museum and Art Gallery Committee of the York Corporation have decided to hold an exhibition of the works of this famous family of artists in August next. William Moore, sen., was a resident in York, and a painter of portraits and miniatures of great merit. Five of his sons made painting their profession. Edwin and William Moore, jun., who practised as teachers of drawing and painting in the City of York, were also artists of more than ordinary ability. John Collingham Moore, Henry Moore, R.A., and Albert Moore, sought a wider field for their talents in London. J. C. Moore was a portrait and landscape painter of recognised ability; Henry Moore, R.A., a distinguished marine and landscape painter; Albert Moore's work was decorative, and he was unrivalled as an idealistic artist and colourist. It is hoped that corporations and private persons owning works by any member of the Moore family will lend them to the York Corporation for the purposes of this exhibition.

MEMORIAL TABLETS.—The London County Council have recently affixed a tablet to No. 88, Paradise Street, Rotherhithe, to commemorate the fact that it was the residence, in 1841, of Thomas Henry Huxley. At this time Huxley, then in his sixteenth year, had just come up to London to begin his study of medicine, and was acting as assistant to a certain Dr. Chandler, as a practical preliminary to walking the hospitals. This is the second house which has been marked as a residence of Huxley, a tablet having been affixed some time ago to No. 4, Marlborough Place, St. John's Wood, which was for many years the home of the great biologist. A tablet has also been placed upon No. 12, Seymour Street, Portman Square, which appears to have been for three or four years the residence of Michael William Balfe, the composer.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS' SCHOLARSHIP.—A scholarship of the annual value of £50, and tenable for two years, will be offered for competition among graduates of the North-East Coast Institution of Engineers and Shipbuilders in September, 1912. The Scholarship will be awarded on the results of an examination held in Newcastle during the month of September, simultaneously with the matriculation examination of Durham University, in English, mathematics, and experimental science. Every candidate for the scholarship shall be a British subject and a member of the graduate section of the Institution of not less than one year's standing; and shall have served or be serving an apprenticeship on the north-east coast. The successful candidate shall undertake to remain a member of the aforesaid graduate section during the tenure of the scholarship; he shall attend a college or technical school on the north-east coast of England; and only under special circumstances will the council consider any application to attend a college or technical school elsewhere. Candidates for the scholarship must forward a written application on the prescribed form to the Secretary of the Institution, on or before the first day of August.

FLANNELETTE.—The British Fire Prevention Committee has recently tested some flannelette costing 8¾*d.* per yard, which was sold and invoiced as "safety" flannelette, by a large London drapery house, to representatives of the National League for Physical Education. Far from being a safety flannelette, or giving any safety against ignition or rapid flaming, this flannelette, of which some fifty yards were under test, flamed rapidly in the most dangerous manner and, in fact, practically the whole of every square yard under test was consumed within a few seconds when a lighted taper was applied thereto. The results of these comprehensive tests have now been published by the committee, in the form of an illustrated report, and the committee in its preamble say that it is desirable that the public should be protected from buying a material of the inflammable nature of which they are ignorant, and they suggest that legislation should be promptly instituted to protect against such a misnomer as "safety" flannelette, and that to sell a textile falsely as safe should be an offence made punishable by ordinary procedure, much as the sale of a false produce or article of consumption is promptly punishable. It should always be remembered that whilst there is a very great outcry if two or three lives are lost at any one actual fire in the Metropolis, the constant sequence of deaths amongst children, either entirely due to the dangers of flannelette, or due to causes in which the wearing of flannelette is the primary evil, has amounted during the last few years to about 1,200 to 1,400 lives per annum.

Consumption of Gofio in the Canary Islands.—Gofio is a name applied in the Canary Islands to a food obtained by roasting and grinding grain. The word "gofio" comes from the Guanchos, a Hamitic people numerous in the islands before their subjugation by the Spaniards in the fifteenth century, and the food is thought to have originated with them. As different grains are used, there are many varieties of gofio. Maize, wheat and barley are commonly used, but any edible grain or seed is considered suitable, especially in times of scarcity. Gofio was originally used in a few other countries—for instance, in India—but it is not found in Madeira, the Azores, or Cape Verde Islands. Lately it has been introduced into Cuba, Porto Rico, and into those parts of South and Central America and the West Indies where former inhabitants of the Canary Islands have made their homes. The best gofio is made of 90 per cent. maize and 10 per cent. wheat, together with some salt, which, however, is not added until the food is to be eaten. If added sooner the salt seems to hasten mildew. In Hierro and Gomera, the most westerly islands of the archipelago, barley alone is used in the preparation of gofio. In the Island of Teneriffe 75 per cent. of the inhabitants subsist almost entirely on gofio, while probably 90 per cent. use it to some extent. In some localities in the country districts the natives have a peculiar way of preparing this staple article of food. After the addition of either milk or water, to obtain a doughy consistency, the mass is put in a "surrón," or the skin of a young kid made into a bag. The bag is then manipulated until the mass becomes as hard as the maker desires. Afterwards it is eaten with cheese, sardines, etc. Others prefer to eat it in the powdered state thrown into coffee, milk, water, soup, etc. Figs, salt fish, and pork form the remainder of a labourer's diet.

Production of Greenstone in New Zealand.—An important discovery is reported of a large outcrop of greenstone in an hitherto unexplored mountainous district, on the west coast of the south island of New Zealand, which is thought to be the original mother-reef from which all the greenstone found in that island is derived. It is anticipated that it will hereafter be so plentiful that its use will no longer be confined to local souvenir jewellery, but will be used for mantelpieces, table-tops, monuments, etc., and will also be exported to China, where greenstone in the form of jade is regarded with peculiar veneration. Up to the present time there has been no systematic mining or quarrying of greenstone in New Zealand, though the Maoris have obtained it from the beds of streams, using it for axe-heads and for personal adornment, and it has also been found with more or less frequency in the south island in sluicing for gold. New Zealand greenstone jewellery is very popular with tourists, though not all of it is real greenstone. It is largely used for brooches, bracelets, cuff-links, waistcoat buttons, etc. The region on the west coast where the present discovery has been made, was recently partially explored by the New Zealand Geological Survey, which predicted that large segregations of this greenstone, or mineral nephrite, would be found in the future, that undoubtedly many tons of fair quality could be obtained from this locality, and that rubies and copper ore, of which evidences were seen, may also be plentiful.

MEETINGS FOR THE ENSUING WEEK.

Monday, May 20...Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Captain H. Riall Sankey, "Heavy Oil Engines." (Lecture IV.)

Geographical, Burlington-gardens, W., 3 p.m. Anniversary.

British Architects, 9, Conduit-street, W., 8 p.m. Mr. R. A. Cram, "Recent University Architecture in the United States."

Victoria Institute, 1, Robert-street, Adelphi, W.C., 4.30 p.m. Rev. E. A. Edghill, "Miraculous Christianity and the Supernatural Christ."

Tuesday, May 21...Royal Society of Arts, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Hon. J. G. Jenkins, "Australian Railways."

Asiatic, 22, Albemarle-street, W., 4 p.m. Anniversary.

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. Bateson, "The Study of Genetics." (Lecture II.)

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. J. D. Johnston, "Spring under Italian Skies."

Zoological, Regent's-park, N.W., 8.30 p.m. 1. Mr. A. Blayney Percival, "Lantern Exhibition of Game Animals from British East Africa." 2. Major J. Stevenson Hamilton, "The Local Races of Burchell's Zebra." 3. Dr. William Nicoll, "On Two New Larval Trematodes from the Striped Snake." 4. Dr. W. T. Calman, "On *Dipteropeltis*, a New Genus of the Crustacean Order Branchiura." 5. Mr. G. A. Boulenger, "Second Contribution to our Knowledge of the Varieties of the Wall-Lizard (*Lacerta muralis*)." 6. Sir Charles Eliot, "A Note on the Rare British Nudibranch *Hancockia eudactylota* Gosse."

Wednesday, May 22...Meteorological, 70, Victoria-street, S.W., 4.30 p.m. 1. Mr. C. J. P. Cave, "The Thunderstorm of March 11th, 1912, in Hampshire and Sussex." 2. Mr. Eric S. Bruce, "The Automatic Release of Self-Recording Instruments from Ballons-Sondes."

Economics and Political Science, London School of, Clare-market, Kingsway, W.C., 5 p.m. Mr. H. J. Mackinder, "The Geography of China."

Royal Society of Literature, 20 Hanover-square, W., 5 p.m. Mr. A. E. Morgan, "English Domestic Drama."

Thursday, May 23...Antiquaries, Burlington House, W., 8.30 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor H. T. Barnes, "Ice Formation in Canada. II.—The Economic Aspect." (Lecture II.)

Friday, May 24...Royal Institution, Albemarle-street, W., 9 p.m. Mr. A. D. Hall, "Recent Advances in Agricultural Science: The Fertility of the Soil."

Junior Institution of Engineers, 39, Victoria-street, S.W., 8 p.m. Mr. S. H. Hole, "Brewery Plant."

Linnean, Burlington House, W., 3 p.m. Anniversary.

Saturday, May 25...Royal Institution, Albemarle-street, W., 3 p.m. Mr. H. Plunkett Greene, "Interpretation in Song. Lecture III.—Songs and their Classification."

Journal of the Royal Society of Arts.

No. 3,105. VOL. LX.

FRIDAY, MAY 24, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

HOWARD LECTURE.

On Monday evening, May 20th, CAPTAIN H. RIALL SANKEY, R.E. (retired), M.Inst.C.E., delivered the fourth and final lecture of his course on "Heavy Oil Engines."

On the motion of the Chairman, a vote of thanks was accorded to Captain Riall Sankey for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Tuesday afternoon, May 21st; THE RIGHT HON. LORD EMMOTT, Under-Secretary of State for the Colonies, in the chair. As his Lordship was compelled to leave before the close of the meeting, the chair was subsequently occupied by COLONEL SIR THOMAS H. HOLDICH, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc. A paper on "Australian Railways" was read by THE HON. J. G. JENKINS.

The paper and discussion will be published in a subsequent number of the *Journal.*

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A meeting of the Colonial Section was held on Tuesday, May 7th, 1912; THE RIGHT HON. SIR WALTER F. HELY-HUTCHINSON, G.C.M.G., in the chair.

THE CHAIRMAN said Mr. Burgoyne hardly needed an introduction, as he was a well-known rising politician interested in a great Australian firm of wine growers. The paper was one of a series which were to be read before the Society by experts dealing with the various products of the Empire.

The paper read was—

COLONIAL VINE CULTURE.

By ALAN H. BURGOYNE, M.P.

It is the barest platitude to say that not one of us in a thousand could, were the question put to us, state the genesis, sketch the history, or trace the development of the myriad articles with which, in the commonplaces of our civilisation, we daily come into contact. The man who invented the hair-pin is said to have made a fortune—I do not know in what century he lived! The history of submarine navigation began in the days of Aristotle, 322 B.C.—and roast pork, the story goes, was discovered by the accidental conflagration of a pig-sty. These are of the salt of knowledge—they can be extended indefinitely. To-day it is the turn of the vine—and especially its development as a beverage provider within the confines of our great Empire. Of the first knowledge that grape-juice was palatable, history tells us nothing. Tradition states that, in the days of woad and flint-head axes, a wife of Gaul, wishing to take advantage of the plenteous crop of her good man's vineyard, piled in an earthen jar the luscious bunches of fruit and placed thereon a cover—weighting it down with stones. One day, natural fermentation caused a crack in the jar, and from it the concentrating juices slowly dripped. To protect the floor a beaker was placed beneath, and this in course of time filled. The husband, returning hot and thirsty from the chase, seized the brimming bowl and took a deep draught. Whether the joy that followed compensated in advance for the morning of the next day is not related, but in this way the stimulating and invigorating qualities of the grape first came to man. At least, so tradition tells us—and this tradition pre-dates Bacchus by many a thousand years.

It is not my intention, nor indeed the reason of my being here this afternoon, to deal with the

Hosted by Google

general history of vine cultivation or wine making. This subject has already been before your Society; my present motive is more national and Imperial. It is not worth while travelling outside the bounds of commercial enterprise in this matter. I have seen it stated that wine has, in recent years, been made in Wales and Egypt, but in neither case was it other than an experiment, more fantastic than utilitarian. Two great Dominions have applied themselves earnestly to the art of wine making —the Commonwealth of Australia and the United South Africa. The Dominion of Canada has executed spasmodic movements of more local than national interest, whilst Cyprus, a Crown possession, is comparable, as to future progress, to neither of the countries already named.

We will take the last named first in order, and see how matters have gone. Let this at once be said of Cyprus, that it is abundantly provided by nature as a wine-making island. Its situation, broken surface, variety of elevation from the sea-level up to 6,000 feet, associated with an even, dependable climate and season-temperature, render it fortunate in all that side of the science of vine culture in which nature is the governing factor. As against this, however, must be set the hopeless ignorance and sad poverty of the natives— a state in which they would seem to have existed from the very earliest time. Cyprus has always been regarded as the most eminent of the vine-producing islands of the Grecian Archipelago, and—again we must fall back upon tradition—was consecrated to Venus on account of its great fertility and vast natural riches. Of this fertility we obtain some glimpse by the statement of Pliny, who wrote: "Even at the present day we ascend to the roof of the Temple of Diana of Ephesus by stairs constructed of a single vine that was brought from Cyprus, where the vines often attain to a remarkable size." This striking and historical testimony to the profuse powers of vegetation is upheld by the size and luxurious sweetness of Cyprus grapes to-day.

The two favourite varieties of vine are the Mavro and Xynesteria (Professor Mouillefert, Grignon Agricultural College), whilst a third, the Ophthalmon, is also popular though unfortunately subject to oidium. The difficulty of growing is accentuated by the necessity of terracing the slopes, and much labour is expended annually in carrying up and replacing the top soil washed down from the hills by the winter rains. The system of pruning most in vogue is that known as the "Willow-Head" (*tête de saule*), which consists in cutting back all the shoots quite closely every year until the vine has the appearance of a pollard willow. The *raison d'être* of this custom is that anyone can be entrusted with the work—but, of course, the yield suffers greatly through the simplicity and almost brutality of the operation.

The process of wine making, once the grapes have been gathered, is just as it was many centuries ago. The berries are trodden out with the feet in any convenient spot, and the resultant "must" is fermented in porous earthenware jars holding from 40 to 60 gallons. These jars are coated with tar inside and out, and any of you who have drunk the natural Cyprus wines will have noticed, as a natural consequence, a distinct tar-flavour. Clarification of a sort is effected by constant changes from jar to jar, but, since they are not closed down for the first year, much of the wine becomes impregnated with acetic acid. Cyprus Vin Ordinaire is not, therefore, a beverage to be recommended to those travelling in the country; it is not only the worst of the wines made, but it is taken to the inns and hotels by the vignerons in skins even more highly tarred than the fermenting jars. Really drinkable wines, which are sold new, find a ready market in Syria and Trieste, and of these perhaps the favourite variety is one with the generic name, Commandaria. This name is derived from a Command of the Knights Templars established at Colossi, near Limassol, whose house still exists. Commandaria is a name given to a considerable series of sweet wines which are made from grapes half-dried in the sun, often on the flat roofs of the houses, prior to fermentation; this, it need scarcely be said, is for the purpose of increasing the saccharine strength. At a year old, Commandaria is carmine in colour, becoming paler and browner in keeping as also sweeter and more syrupy to the palate. During each of the first few years the loss by evaporation amounts to 10 per cent. The total consumable output of Commandaria is only about 50,000 gallons annually, but in bottle it becomes with age one of the first wines in the world. Indeed, so exquisite is it held to be by some, that Philip Augustus called it the "Pope of Wines." The yield of Commandaria is only 60 to 80 gallons per acre.

Next to Commandaria is the Cyprus liqueur, made from the native brandy, of which about 150,000 gallons are distilled every year. This

Hosted by Google

is flavoured with aniseed and mastic, and is the most popular and common liqueur in the Levant. The commonest wine of the island, Mavro, represents about two-thirds of the total production, and is an inferior type of brusque Burgundy, strongly impregnated with tar. At Omodos a species of Muscat is made—this is mentioned as a matter of interest only, its quality is very limited.

Viticultural expansion, apart from the difficulties with the growers, is hampered by an arbitrary and complicated system of assessment of the duty payable upon all wines—good, bad or indifferent, and whether sold, consumed or thrown away. It is supposed to represent a duty of 12 per cent. upon their alleged value.

I have no figures of recent date, viticulture not being thought worthy of mention in any of the annual reports of Cyprus now issued. The following figures suffice, however, to show the progress of wine making in this island—the demand being mostly stimulated from Austro-Hungary.

1878–84.	Average production	1,770,000 gallons.
1884–90.	,, ,,	2,490,000 ,,
1890–96.	,, ,,	3,100,000 ,,

From Cyprus we take passage direct to Canada, and frankly must the confession be made, the writings and chronicles of viticulture in our huge American Dominion are so few that practically nothing is known of its history. We first hear of grapes in the account given by the explorer Cartier, in his Canadian travels, published in Paris in 1545. In describing the St. Lawrence River, he speaks of an island at its mouth where he was not only astonished at the rich abundance of the vines but also at the quality of the grapes ripening upon them. He named it at once the Isle of Bacchus; at the present time it is called the Isle of Orleans.

Of the fitness of certain districts of Canada for vine-growing there can be no doubt. The Niagara section of Ontario, for instance, is famous for its fruit, and to the extreme south-west there is a peninsula of land between Lake Erie and Lake St. Clair, consisting of the counties of Essex and Kent (including Pelee Island) where the vine flourishes marvellously. Along the Detroit River and on Pelee Island there is extensive cultivation of grapes, and quite a quantity of wine is made. On Pelee Island alone there are 350 acres of vines, and over 500 tons of grapes have been pressed in one year by the Pelee Island Wine Company. In 1896, there were 2,000,000 vines growing in the Provinces of Ontario.

Turning to Cape Colony, we first hear of vines there on their introduction by the early Dutch settlers in 1653. Their success induced these pioneers to import in 1656 still a further supply of cuttings, and we have an account of a vintage made from a species of Muscat grape in that year.

Without desire to dwell too long upon the historical side of the development of viticulture in Africa, a few points are not without interest as tracing its history.

In 1861 brandy was made, and six years later, according to the first census taken at the Cape, there were half a million vines in cultivation in the Colony. Until this time the business and methods had been of a very rudimentary character, and the vines were regarded much as the good housewife in the west country looks after her two rows of gooseberry-bushes.

With the coming of the Huguenots, however, in 1688, a sudden development upon practical lines was made, for they brought not only a knowledge of wine making, but also a large range of varieties of grape from the south of France, including the small Muscat type of Frontignan. Let it be said here that the conditions existing in Cape Colony are, if careful selection of ground be made, ideal for vine growing, but largely owing to the indolence and ignorance of those engaging in it, the rich, flat lands were chiefly chosen for the planting of vineyards, rather than well-trained hill-sides fitted by nature for terracing and easy culture. A further fault, and one which it must be admitted is to be chronicled in other countries besides Cape Colony, was the desire evinced to obtain the heaviest crop regardless of the quality of the grape. Sterne, in his "Sentimental Journey," says—

"The man who first transplanted the grape of Burgundy to the Cape of Good Hope (observe that he was a Dutchman) never dreamt of drinking the same wine at the Cape that the like grape produced upon French soil—he was too phlegmatic for that. Undoubtedly, he expected to drink some sort of vinous liquor; but whether good, bad, or indifferent, he knew enough of this world to see that it did not depend upon his choice, but that what is generally called chance was to decide his success. He, however, hoped for the best; and in these hopes, by an intemperate confidence in the fortitude of his head and the depth of his discretion, Mynheer might possibly overset both in his new vineyard, and, by discovering his own nakedness, become a laughing-stock to his people."

Without justifying this comment, the wine produced at the Cape found immediate popu-

Hosted by Google

larity and local favour, and this though at no time have the huge natural possibilities of the country been taken advantage of for the development of vineyards.

In 1880 there were 20,000 acres under vines, planted very closely, between two feet and three feet apart. This cultivation was, and still is, largely confined to the Western Provinces owing to exceptional climatic conditions, conditions which account not a little for the productivity of the vines in Cape Colony. The principal wine-growing districts are:—The Cape, Stellenbosch, Paarl, Malmesbury, Worcester, Robertson, Montague, Ladysmith, Prince Albert, and Oudtshoorn. These can best be dealt with if divided into two sections—the coastal section and the inland section—the first four mentioned, *i.e.*, The Cape, Stellenbosch, Paarl and Malmesbury coming under the former category, the remainder belonging to the latter.

Dealing with the coastal section, the soil is largely intermingled with granite, and the foremost vineyards—Constantia, Bottelary, Moddergat, Jonkers Hock, Paarl and Groeneberg, names well known to those who have made a study of the subject—are all planted on hill-sides and granite soil. There can be no question of the superiority of these vineyards as against those planted upon alluvial flats, for the soils here, though of great variety, are all deficient in lime; let me hasten to state that excellent results have been and are being obtained by the addition of lime as a manure.

The rainfall of the coastal districts, to proceed with their description, is altogether favourable to successful vine culture, for it ranges from about forty inches at Constantia to twenty-four inches at Stellenbosch. The peculiarity of the rainfall, which quoted in the aggregate seems very unusual, is its even distribution all through the winter to the spring, when a dry summer following ensures a careful and equable ripening with an obvious freedom from all fungoid diseases. It is quite exceptional for the grapes to suffer by the rain.

The physical condition and chemical composition of the soil of the inland section of the vineyards is unique, and accounts for their remarkable powers of production. In the first place a bed of ferruginous marl, the so-called "kalk-bank," stretches very many miles through the lowland districts of Worcester, Robertson, Montague, Ladysmith and Oudtshoorn. An extensive belt of this remarkable soil stretches right across the Colony. This marl tends to, and frequently does, change to calcareous clay, which rapidly decomposes and forms a rich, loose and deep soil, the fertility of which is not equalled in the whole of the African continent.

This statement might best be exemplified by mentioning that the average yields of the Cape, Stellenbosch, Paarl and Malmesbury districts are 570 gallons of better-class wine per acre, whilst in the lowland districts just described, the average of similar wines is 1,100 gallons per acre, and many vine-growers obtain no less than 2,000 gallons per acre regularly! Baron von Babo, a son of the celebrated Austrian authority, who devoted much time during his years of employment by the Government in the Cape to the study of this question, gives the average yield as follows:—

The coastal sections	770	gallons per acre.
The inland „	1,600	„ „ „

The heavy-bearing districts produce wine of considerable alcoholic strength, superior indeed to that of the south of France. This is from a grape locally known as "Haanepoot," which would seem to be derived from the Gordo Blanco. It is a wine possessing a pronounced flavour of Muscat, and appears to be in high favour for distilling, more so indeed than for consumption as a beverage.

In 1891, 6,000,000 gallons of wine were made, and 1,400,000 gallons of brandy, so that in that year a somewhat larger quantity than the year's production of wine must have been distilled.

Haanepoot is subject to all fungus diseases, and in consequence is less popular than the Green grape, a kind of sweet-water or Chasselas, which seems to thrive even under neglected conditions, and is suitable for a class of agriculturists not renowned for their exertions.

It is the small Muscat of Frontignan from which the famous Constantia is made. Constantia is a sweet wine of considerable merit, but these syrupy productions, which at one time were much sought after on account of their undoubted quality, have largely been killed as to favour by the growing demand for brandy, and the cheap, sweet fortified wine, the popularity of which, curious as it may seem to those appreciating good wines, is growing in every wine-making country in the world.

The fortification of carelessly made wine naturally tends to promote persistent carelessness in handling and manufacture. Without any desire to be unfair to a once prosperous industry, there is no doubt that the Cape market is largely being spoiled by the inefficient and sloppy methods of the wine maker.

The Government early recognised this failing,

Hosted by Google

and, with a view to remedying it, purchased the Groot Constantia vineyard as an experimental vineyard and a training ground for future vine growers. Sufficient time has, as yet, not elapsed to say whether or not this move was justified, but it seems sound and common-sense in the circumstances, and we may look to very different results as time goes on.

Phylloxera, that constant fear and unfightable curse of the vineyard proprietor, was discovered in 1886 in Cape Colony and has done an infinity of damage, but replanting upon American phylloxera-resistant roots is now taking place, in the face of the prejudice and ignorance of the Dutch farmer.

To show you how little care was given to the vines at the period when the most care was necessary, the following suggestion from an experienced wine grower, writing in 1886, seems a little out of the common. He advocated the use of scissors, or the use of a sharp knife, for pruning vines, saying: "It is marvellous how vines can at all sustain the rough treatment of a club-stick or a hatchet with which the young branches are too frequently broken off!"

Table wines made from Pontac, Riesling and Stein grapes possess sufficient delicacy to warrant their manufacture upon an extensive scale, but with such local demand as at present exists in this rapidly growing country we cannot look forward to much export. Even the brandy, or Cape smoke, as it is called, is unlikely to find an outside market for some years with the present primitive methods of distillation. It may also be added that both raisins and currants are largely produced and asked for, whilst the fresh grape export trade is growing fast.

In concluding this section of my paper it is interesting to note that Professor M. P. Mouillefert, who visited Africa a short time ago, stated that he saw vines growing near Cape Town which had originally been planted in the late seventeenth and eighteenth centuries.

The continent of Australia presents many paradoxes of nature. We have all heard that its flowers have no smell, that the birds indigenous to it have no song, and this, too, is equally certain, that the first white settlers found no trace of native edible fruits.

To those who know the productivity of the country at the present time, this fact will appear remarkable, and perhaps in no single instance more so than in the case of the vine.

Speaking of the country as a whole, there can be no land in the universe with a higher percentage of acres fitted for cultivation, and, at the same time, equally fitted for the development of wine-making grapes. Thus we find that, with the white man, has come the successful growth not only of such fruits distant the one from the other as pineapples, bananas, peaches, guavas, apples, pears, passion-fruit, plums, strawberries, cherries, but also the grape in every variety and for every purpose to which it can be put.

Not a little romance surrounds the introduction of the vine into Australia. It would seem that in the years 1815–16, at the termination of the Napoleonic campaign, subsequent to the battle of Waterloo, one, Captain John MacArthur, with his two sons, journeyed on foot from district to district of those parts of Europe whence wines had already come, and where the culture of the vine was the chief feature of the countryside. This journey must have been indeed adventurous, since every high road was infested with footpads and camp followers—those bad characters and human outcasts always so common during and after a long international war.

The result of this extended tramp was a bundle of vine cuttings representative of each district visited. These were taken with not a little jubilation back to the Antipodes, and at once efforts were made to propagate them. These cuttings were found, however, after cultivation until fruit-bearing, to the great dismay of those who had collected them with so much trouble, to be in almost every case worthless.

In 1825, the Australian Agricultural Company imported a few vines from the Royal Horticultural Society, which then had its gardens at Chiswick.

In 1831, James Busby brought from Australia to England the first wine, made near Sydney in the previous year. This was placed before a number of London wine merchants, who described it as a species of Burgundy, and it says much for its manufacture that when some of it, re-exported to Sydney, was opened out there it was found to be perfectly sound.

In 1832, this Mr. Busby obtained, at his own expense, 570 varieties of vines from the collection formed at the instigation of Napoleon by the Comte de Chaptal, at Luxembourg Gardens in Paris, and from Montpelier, even then a leading centre for the scientific study of the vine.

Of these 570 varieties, no less than 362 were successfully struck by Mr. McLean, head of the Sydney Botanic Gardens. It must be remembered that these cuttings, during transportation,

Hosted by Google

in the first place had to be kept alive, and secondly, were upon the sea for from four to eight months—for I need hardly remind you that the Suez Canal was non-existent, nor had a steamship ever rounded the Cape.

Busby sent his first selection by a convict ship by permission of the then Secretary of State for the Colonies, and packed the rootlings in cases full of damp moss lined round the sides with damp-proof paper. The man in charge found that a few of them had struck *en voyage*. He, therefore, planted them on the deck in open boxes, where it was part of the convicts' duty to water them. The method of packing outlined above is, it is interesting to recall, the same as that employed to-day. These vines were subjected to tests by Mr., afterwards Sir William MacArthur, and his first selection of 140 varieties was reduced on further consideration to twenty types as being most suitable for wine making. Sir William MacArthur planted his vineyard at Camden Park from these cuttings, and to his enterprise and careful discrimination the present high state of viticulture in the Commonwealth is in a large measure due. It is apposite to remark here that every vineyard now in existence in Australia saw its genesis in cuttings supplied from Camden Park, and Sir William was at all times careful that only the finest varieties were sent round, and rigidly excluded from his choice the heavy-bearing but inferior types which have militated in many districts in other countries against the quality of the wines produced.

It may be said here that Australia is indebted to the MacArthur family for many things besides the introduction of the vine, for it was Captain John MacArthur who imported the Merino sheep given him, it is said, by George III, in 1804, and this at a time when the exportation of Merino sheep was a capital offence in Spain.

In 1837, one Joubert is chronicled as having brought out a collection of the best varieties of the Médoc. From then onwards travellers added to the establishment of the vine, and we may leave that side of the question to consider one or two features of its development which, I think, will be found instructive if not entertaining.

Up to 1838, convict labour was almost the only labour obtainable. The blacks, who represent an unusually low stage of mental development, proved not only troublesome but possessed a mania for murder, whilst the damage done by escaped convicts in their bush-ranging escapades have made history in Australia not to be equalled by any other country. The convicts were assigned to landholders as labourers in the proportion of one to every forty acres. The difficulties of transport were enormous; there were no roads and precious little water. James MacArthur, disheartened by local conditions and the absence of skilled labour, imported six families of German vine-dressers, resulting in great advantage to the industry, and we find that in 1850 there were in New South Wales 1,069 acres; in South Australia 282, and in Victoria 164 acres of land under cultivation for vines. In 1852 a great set-back was experienced, consequent on the discovery of gold, which resulted in practically the whole of the population of the continent engaging in the rush towards the diggings, and it is no exaggeration to say that there were no terms within the comprehension and wealth of landowners which could procure labour for the development of vineyards.

Visiting the diggings during this gold boom, the then proprietor of the *Melbourne Argus*, Mr. Edward Wilson, was told by a Frenchman that Australia's greatest wealth lay in her soil and climate, which were so admirably fitted by nature for the production of the vine. It is a pleasure to say here that this newspaper has at all times strongly supported the development of wine making so powerfully advocated by the original owner.

An elaborate scheme was prepared by the Government of Victoria for reserving large areas of Crown land for agricultural education, for the establishment of agricultural colleges under skilled directors and instructors, and an offer was also made of £2 bonus for every acre planted. The educational side of the scheme received little support, but the bonus had an immediate effect, as the following shows, particularly in Victoria:—

	1850.	1859.	1872.	
New South Wales .	1,069	1,200	4,152	acres.
South Australia . .	282	2,200	6,131	,,
Victoria	164	540	5,523	,,

It is fortunate, in view of the ignorance frequently displayed by those induced to undertake vine growing by this bonus, that there was amongst them a large percentage of men possessed not only of enthusiasm and enterprise, but also of capacity. The pioneers of this movement deserve mention, among them Morris, Smith, Graham, and Caughey at Rutherglen; Bear, Blayney, and Darveniza in

Hosted by Google

Goulburn Valley; de Castella and de Pury at Lilydale, and Best at Great Western, have all done a lot to aid the forward movement. South Australia was even more fortunate, for in addition to such practical men as Davenport, Seppelt, Auld, Penfold, Gilbert and Dr. Kelly, they had in the latter a theorist of premier worth, whose book, "The Vine in Australia," is to this day one of the most remarkable and instructive works ever written upon the subject of vine growing.

In New South Wales, the MacArthurs, Wyndham, Lindeman, Wilkinson and Carmichael are amongst the best-known names, and all those mentioned, whatever the State to which they belong, will be remembered for the courage and perseverance with which they met difficulties, of the immensity of which we, who visit Australia in the heyday of its development, can have no knowledge. It is a testimonial to the personal worth of these early pioneers, that to this day their wood shanties made from trees cut down by themselves, boards hewed out by their own personal energy, are yet to be found upon the vineyards of which they were the first men to turn a sod.

Amongst other difficulties they were called upon to face was the absence of merchants, with the consequence that a grower possessing no knowledge of business was called upon to market his own goods. It is possible that this was largely why, for many years, general farming and harvesting were combined with vine growing; in addition to this, colonial wine was practically banned in the hotels of the country, whilst under the licensing system at that time in vogue no other place for its consumption could be reached. For a time, therefore, a glut of wine was found upon the market, and the owners found difficulty in disposing of their stocks—a very different state of affairs from that existing to-day when, thanks to the appreciation of the British public, the demand for the first and most important growths always exceeds the maximum supply.

Now let me give you one or two milestones in this entertaining history.

Though small quantities of wine had reached England, as already stated, from the earliest times, its importation upon a large scale did not commence until the year 1871. Since that time the imports have merely been governed by the output of wine suitable for exportation, an extraordinary state of affairs—and, indeed, one most satisfactory—that probably has no precedent in any other industry or business.

In 1878 phylloxera was first discovered at Geelong, and to-day, thirty-four years later, we are passing through years of the greatest stress that have followed from the development of this pest at that date. Whilst on the subject of phylloxera—so that it is unnecessary again to revert to it—it may at once be said that most strenuous efforts are being made in all directions to meet the evils as they arise, and to reconstitute the devastated vineyards with resistant stock of the finest qualities.

To go back to the historical side of it, two years later, in 1880, the Victorian Government uprooted every vine in the districts affected in a vain endeavour to eradicate the insect, and the cost borne by them in this fruitless effort amounted to £80,000. In 1884 phylloxera, spreading like some death-wave across the continent, reached Bendigo. In 1898 it had seized the vast wine-producing centre of Rutherglen, and in 1901 Goulburn Valley fell a victim to its ravages. The effect upon the vineyards, once it had attacked them, is almost beyond belief. The first sign the vine grower has of his vineyard being affected is finding isolated sections of it with a few vines in it of more or less stunted growth. These patches of stunted growth spread from the centre outwards like a drop of oil upon the surface of the water, so that within one year, or at most three, the affected areas join, and the whole vineyard is destroyed. Instances are frequent where, even in full growth, and bearing large crops, the vine fails suddenly a month or more before the vintage season, the leaves withering, the berries shrivelling, the crop being lost, and the vines eventually dying. In the whole history of the soil, be it applied to little shrub or giant tree, there is no sadder thing than an attack of phylloxera upon a vineyard.

Leaving the historical side of the question, I would turn for a moment to a short consideration of the soils to be found there—the climate, the method of cultivation, and the education promoted for the future welfare of the industry.

The soils most common in the districts so far developed are alluvial, though evidence of volcanic matter, as also granite, is by no means infrequent. A most common soil, perfect for the nourishment of the vine, is the red ferruginous clay loam with the occasional white quartz so common in and around Rutherglen, and particularly on the vineyards of Mount Ophir. Indeed, the most striking features of this district are the enormous piles of white quartz all round the vineyards which have been

Hosted by Google

thrown up from the old gold-mine workings. It is not perhaps known that Rutherglen almost weekly develops towards a prominent position amongst big townships of Australia, and is named after the birthplace of its founder, and for many years its chief publican, Mr. John A. Wallace, one of the most successful of Australian gold-miners.

The climate of Australia is, if the term may be permitted, of a most contradictory nature. It is perfect if it is certain, and imperfect in its uncertainty. There is no specific rain season, and when rain does fall—if it does, which is a matter of Providence—there is a very low average as compared with that of the vine districts of Europe. The annual average at Rutherglen is but 21 ins.; it is 40 ins. on the Hunter and Lilydale, and only 9 ins. at Mildura. The dryness of this last-named place makes it most suitable for sun-dried fruit, and the very finest raisins, currants and sultanas are produced there by scientific irrigation. This market is now so prosperous that Australia is able entirely to support herself in so far as raisins are concerned, and within the next few years no more currants will need to be imported. The dryness is a blessing disguised in one way, in that the vines will not suffer from fungoid diseases. One day of hot wind will do more to check oidium than many tons of sulphur. Black rot and mildew are quite unknown, and it is seldom necessary to spray a vineyard, so easily can oidium be kept in check.

Regarding cultivation, two methods seem general—trellis and gooseberry-bush shape. To gain all advantage possible from the Antipodean situation of the part of the continent under discussion, the rows are planted in the same direction as the most prevalent hot winds, and the distance between each root varies from 8 ft. by 8 ft. to 10 ft. by 10 ft., and even 12 ft. by 12 ft. As a consequence, the yields per acre are proportionately small in comparison with those of other countries. Australians, however, take their vine growing seriously, no nation more so, and it is a privilege to pay a tribute to their prowess, and congratulate them upon their keen enterprise where the matter of vine cultivation is concerned. Their vineyard ploughs are far in advance of those used in Europe; there have been multiple furrow ploughs in general use for well over thirty years. They use short mould-boards to lighten the draught, with the natural result that the work is far more quickly done and at less expense.

The vintage commences about the end of February, and continues through March. Labour, owing to two causes—the fact that the country is new, and that it has suffered from a superabundance of ultra-democratic legislation—is both difficult to obtain and expensive to pay. Last year, boys (which means under sixteen years of age) had a minimum wage of 6*s.* per day, and earned 7*s.* 6*d.* on piece-work per day in south Australia, and it can safely be said that at the present time Australia as a country is the paradise of working-men. Without entering into a controversial subject, which has not only split nations but has dismembered parties, it is of moment to recall that all traders in Australia, under the protection which is part and parcel of the democratic egislation there, must—if their dealings be in imported goods, competing with similar articles manufactured in the Commonwealth—pay to the men they employ in their business a fixed and special wage. It is an undoubted fact that despite these tariffs, high as they are, the Commonwealth as a whole is making remarkable progress as a commercial and industrial centre.

The stemming and crushing is now done by machinery. The "must" is pumped direct into polished cement vats, where fermentation is induced and allowed to take place under the most scientific supervision, and regulated by methods of cooling which it is rare to find in the older established wine-making districts of Europe. The storage casks are erected in magnificent modern buildings. There are huge vessels holding from 1,000 to 5,000 gallons, as a rule made of oak. The reason for this storage in huge bulk is that the climate promotes unusual evaporation in puncheons, hogsheads or similar casks.

The vignerons of to-day have been forced to use their brains in the work in which they are engaged, and to meet a number of difficulties and emergencies unheard of in colder climates. Thus, the heat of early summer, arising not infrequently to 120 degrees in the shade, causes trouble in the matter of expansion; but all these things are accepted as necessary evils, and met with the fortitude based upon keen appreciation of the dangers, and knowledge of how to combat them. This knowledge, largely gained in the field of tried experience, has greatly been added to by the oundation of Government agricultural colleges, those in New South Wales being on the Hawkesbury River and at Wagga Wagga, the two Victorian ones at Longerenong and Dookie, the South Australian

Hosted by Google

college being at Roseworthy, and, furthermore, a start has been made with a species of continuation schools, in the holding of agricultural classes, for boys leaving the compulsory State institutions.

A spirit of independence and an unusual ease in obtaining lucrative and interesting employment in a dozen different directions makes the young Australian disinclined to undergo any lengthy course, whether it be agricultural or otherwise, and this may account to some extent for the almost total failure of the Viticultural College at Rutherglen, which has since been made use of for State wards who are trained as agricultural and viticultural labourers. Furthermore, farmers and their sons attend lectures in various centres during the winter months. A course of instruction is given them by a staff of experts kept constantly on the rounds, and these lectures, it is pleasant to add, are annually better attended and the result is already being felt throughout the industry.

One word as to the future of viticulture in Australia. Irrigation is being promoted on the most gigantic scale, and indeed the largest scheme in the world, one under which half as much water again will be retained as by the Assouan Dam on the Nile, is nearing completion at Barren Jack on the Murrumbidgee. Perhaps the first essence of progress lies in the development of closer settlement. This closer settlement, however, must, by the nature of the country and its climate, be dependent upon irrigation, and irrigation as a national proposition and asset is dependent upon payable crops.

The wine produced as the result of irrigation is entirely suited for distilling, and the vines bear also the finest raisins, sultanas, and currants. The distilling side of the business has progressed by leaps and bounds since the imposition of protective duties. These amount as to the Customs to 14*s.* per gallon, and Excise 10*s.* per gallon; however much land be planted and whatever the stocks foreign spirit merchants import, it will be many years before the supply of wine is in any wise commensurate with the demand in the various directions quoted.

This, then, concludes my paper upon vine culture within the British Empire.

It is with great diffidence that I have ventured to read one, and no kindly claim to consideration is or can be made for it, as it does no more than touch upon the merest outlines of the subject; nor have I wished to burden what I have said with technical details, or scientific formulæ, reserving the time and space allotted to me rather for a discursive historical sketch of that which I firmly believe will become one of the most noteworthy and striking industries under the British flag.

I would like to conclude by quoting from a remarkable paper written by Lord Blyth, upon the subject of Vine Culture as exemplified at the Paris Exhibition of 1900. His final words seem to me so apposite to what I have said that I would not alter them by so much as a syllable. He ends a notable collection of facts in this manner—

"If, therefore, the information now presented serve to fix the attention of our own people on the nature and volume of this prodigious industry, the partnership in which should in future belong as much to the British Empire as to the rest of the world, it will be a pleasing recompense for any labour involved in its collection and arrangement. And it will be an additional satisfaction if others are encouraged to pursue further this subject of viticulture, which seems the more inexhaustible the more deeply it is studied."

[The paper was illustrated by a number of lantern slides showing the cultivation of the vine and the making of wine in Australia.]

DISCUSSION.

The Chairman said the paper was a most instructive one, and Mr. Burgoyne was to be congratulated on having produced an address so full of interest. He did not feel well qualified to discuss the paper himself because he was in no sense an expert on the subject. It was true that about thirty-six years ago he visited a vineyard then in course of being newly established near Albury in Australia, and was much struck with the energy and determination shown to get over all the difficulties that lay in the way. In those days Australian wines were somewhat under a cloud, but by the energy of those who took up the matter, including Mr. Burgoyne's family, those difficulties and prejudices had been overcome, and the wines had been successfully placed on the British market. Any slight knowledge he possessed of viticulture and wine making he acquired whilst in South Africa, and he should like to bear testimony to the great and successful efforts that had been made to improve the methods of viticulture and wine making in that country. He could testify to the correctness of what Mr. Burgoyne had said as to the fertility of the lands in South Africa which were used for vine growing. From figures that had been given to him from a reliable source he understood the production per acre in South Africa, in the coast districts, was about six times what it was in Australia and the United States, five times

what it was in France, Austria, and Russia, about four times that of Hungary, Germany, and Algeria, and more than twice that of Switzerland. In the inland districts the production was almost twice as much as that, and the amount of wine that could be produced per acre of soil in some districts was almost unbelievable. He remembered in 1903 going with Mr. Joseph Chamberlain to Graff Reinet, where Mr. Chamberlain was presented with a bunch of grapes such as was seen in the old Biblical pictures of Joshua and Caleb returning from the Promised Land, and carrying on a pole a great bunch of grapes which hung nearly to the ground between them. He hoped Mr. Burgoyne would excuse him when he said that if he had been to South Africa he would have expressed himself rather differently about the Dutch farmers. There was a story told of the late Sir William Butler that he was being consulted by the War Office about what ought to be done in Somaliland, where a certain leader called the Mad Mullah had given a great deal of trouble. Sir William's reply was, "I think you had better begin by leaving off calling him the Mad Mullah." When discussing South African agriculture it might be well to begin by leaving off calling the Dutch farmers ignorant and indolent, because that was a mistake. There were many of them, no doubt, still open to the charge, but the number was steadily diminishing, and there were amongst the Dutch farmers men who were not less progressive in their methods than the most progressive Britishers. Some of them—he did not say wine farmers, for big fortunes were not to be made in the wine industry in South Africa at present—had arrived at financial success greater than any farmer in the United Kingdom could hope to command. To mention names would be invidious; he would only ask Mr. Burgoyne to go there and see for himself, and then probably some of his friends who were so progressive and go-ahead, and had done so much for the wine industry of Australia, might think it worth their while to start in South Africa and see if they could help the South Africans to push along "the old Cape cart," and whether more could be done than was done at present in bringing the South African wines to the notice of the British consumer. Twenty-six years ago a wine farmer now and then might have used a clubstick or a hatchet for cleaning his vines, but such a practice to-day was unheard of. Opposition in days gone by to the importation into a slightly infected district of American stocks which, though they resisted, also brought with them the phylloxera, was not necessarily the outcome of prejudice and ignorance. "Cape smoke" or "dop," which was distilled in primitive fashion from "must" containing grape refuse, was not the only kind of brandy produced in South Africa. The most modern and scientific methods of distillation of brandy from sound wine had long since been introduced. Altogether he felt bound to say, in justice to the South African wine farmers of to-day, that the presentation of the case with regard to the South African wine industry in the paper was scarcely fair to them, and he attributed that, not in any sense to original sin on the part of the author of the paper, but to the fact that he had never been to South Africa to see for himself. His own principal quarrel with the South African viticulturists was that many, if not most, of them did not drink wine; they were almost all teetotalers. Not very many of them actually made the finished article. They pressed out the juice and sold the wine when ten months old to the wine makers in Cape Town and elsewhere, and it was the wine makers, not the wine farmers, who had to be held chiefly responsible for methods which Mr. Burgoyne rightly condemned. He had lived in South Africa for seventeen years, and knew the failings of the Dutch farmers and also their virtues, and they deserved encouragement rather than blame. He had received the following letter from Lord Blyth, who was most anxious to have been present that evening —"I regret extremely that a severe influenza cold confines me to the house, and prevents me supporting your chairmanship to-day, and listening to the address of Mr. Alan Burgoyne upon a subject in which I have from my youth taken a deep interest, viz., Colonial vine culture. Unfortunately the large trade which existed, at the commencement of my commercial career, in wines produced within the Empire, viz., in South Africa, has disappeared almost entirely from our imports. From 1853 to 1859 the vineyards of Europe, as is well known, were ravaged by a disease called the oidium, which facilitated the sale of wines grown in other regions. Our Colonial wines were then also further favoured by a heavy preference in the duty which ceased at the revision of the wine duties in 1860. It is extremely gratifying, therefore, to know that in the new century the whole of that large importation from the Cape had been more than replaced by the wines of an even more distant Dominion of our Empire, in free competition with the whole of the wine-producing countries of the world. Of course, I refer to Australian wines, which during the six years from 1905 to 1910 averaged 760,000 gallons annually, and in the year 1911 reached the record importation of 959,000 gallons. This is the more remarkable if it be borne in mind that the consumption of wine has steadily declined in the United Kingdom, and that the wine imported in 1911 in cask was only 9,846,844 gallons; Australian wines, therefore, being nearly one-tenth of our total importations in wood. Indeed, including the importations in bottle—chiefly sparkling wines—we find that out of every dozen bottles of wine now annually drunk in this country one bottle is from our own Commonwealth. These facts, so gratifying to Australia, are very largely due, in the first place, to the enterprise of Mr. Burgoyne's firm as pioneers, and to others who have followed their lead in making the wines known to the consumers here. We hope that the example thus set will embolden the others of our Dominions oversea to make a bid for public attention to their capabilities

Hosted by Google

in vine culture, which not only, with our present swift communication, means the distribution of our vineyard products in the form of wine, but the shipment of grapes, both fresh and in the form of raisins. I trust that Mr. Alan Burgoyne's most interesting paper, which I have had the honour of perusing, will attract further attention to the suitability of much of the territory of our Empire for grape-culture, an industry which in Europe is only second to that of the growing of corn."

Mr. C. R. Haig said it augured very well for the political future of Mr. Burgoyne that he had so entirely dissociated his paper from puffing the goods in which he himself dealt. He had had the pleasure of the acquaintance of Mr. Burgoyne's father for very many years, and had come in contact with the wines in various ways, as chairman of juries on exhibitions and so on, and it was perfectly wonderful, as Lord Blyth said in his letter, that a stage had been reached in the consumption of Australian wines when one bottle in every twelve of the wines consumed in the United Kingdom came from Australia. The wines of the Empire now began to compete seriously with the wines received from the Continent of Europe. Mr. Burgoyne had done a great service in bringing forward the capabilities of other Colonies with regard to wine growing. He sympathised with the Chairman's remarks defending the Dutch farmers, and was glad to hear that there was a great future for the wine of South Africa if those concerned in it would only follow on the lines which had been laid down with such science and perseverance by the firm to which Mr. Burgoyne belonged. The British people would do well to give Australian wine, and wine grown in other parts of the Empire, a trial as against wine grown in other parts of the world. When chairman of a jury of the Franco-British Exhibition he saw some of the finest specimens of white wine, exhibited by Messrs. Burgoyne, which he had ever seen from any country of Europe or the rest of the world. The fact that such wine had been produced in the course of half a century was a wonderful tribute to the energy of the British race. It should be mentioned that the progress had been made without any protection whatever. When the protective duty was removed from South African wines the consumption fell very largely, but that had been more than replaced by the wine from Australia, which had made its mark here without any protection whatever, and in competition with the whole of the wine-producing world. Therefore it was greatly to the credit of the wine producers and the merchants to have achieved the results they had done, situated as they were 12,000 miles away, and competing with wines coming only a few hundred miles from the Continent of Europe.

Mr. C. du P. Chiappini (Trade Commissioner for the Union), after explaining that he was authorised to speak on behalf of the Government of South Africa, said he must thank the Chairman for his able and sturdy defence of the reputation of his countrymen, and assured him that his action would be very much appreciated in South Africa. They had listened with interest to what Mr. Burgoyne had to say in his paper. He devoted a considerable portion to praising the methods adopted in Australia, while a very large portion of his paper was devoted to condemning the methods in South Africa of the wine producers, his remarks being of a personal nature. While quite agreeing with every word stated in appreciation of the Australians and their methods, the speaker entirely disagreed with the author's remarks having reference to his countrymen. In more than one portion of his paper, Mr. Burgoyne accused the South African wine farmer of ignorance and indolence and prejudice. He would be failing in his duty and lacking in manliness if he allowed these remarks having reference to the Dutch farmers to go forth to the world unchallenged. The speaker was not annoyed, but felt grieved that Mr. Burgoyne should have thought fit to speak of his countrymen in those terms. South Africans were, however, used to imputations of this description, and did not accept them seriously, as it was quite clear that Mr. Burgoyne knew nothing about the conditions prevailing in South Africa: otherwise he would not have made those remarks. The South African wine farmers, far from being ignorant or indolent, were a highly intelligent section of the community, well educated, and knowing their business. They were thrifty, but lived in fine homes of beautiful architecture in lovely surroundings, which in itself would inspire them to rise to a high level. They were descended from a race of gentlemen, and were the aristocrats of South Africa; they provided good education for their children; their sons had filled high places on the judicial bench, which they had adorned with credit to the Empire, while some of them had held distinguished positions in public life, some being Ministers or ex-Ministers, and others prominent members of legislatures of the country; many of them were also leading barristers or members of the medical profession. Turning from the sentimental side, the speaker dealt with the purely commercial side of the question. The South African wine farmer catered for his local market, and had found this more profitable in recent years than endeavouring to create an export trade. South Africa produced over 6,000,000 gallons of wine per annum, which was consumed in that form, and about 1,500,000 gallons of brandy, which was chiefly made from wine. Roughly speaking, South Africa produced about 12,000,000 gallons of wine per annum. South Africa was a large mining country, besides which there were other good paying industries, such as the production of ostrich feathers, mohair, maize, wool, wattle bark, and other industries. The persons engaged therein did not produce wines, but might require them. This constituted the wine growers' local market. The wine farmer found he could get a better price in

Hosted by Google

South Africa than shipping it to this country; and thus catered for the best paying market. This did not indicate ignorance or indolence. If we examined the figures of the British wine trade we should find that the total imports of wines into the United Kingdom was about 13,000,000 gallons per annum. Supposing South Africa was to increase its output to the extent of about 20 per cent. only, and export that quantity to the United Kingdom, how would that affect the price of wines in England, the quantity of wine produced in South Africa being nearly equal to the consumption in England? This increase of 20 per cent. on the South African production would equal about three times the amount of wine now imported from Australia. Only recently he made a report to the Government pointing out that the price of wines had gone up in England, and supplied them with all information connected with the wine trade, and also requested them to forward commercial samples to be submitted to the trade with a view of ascertaining its commercial value. The Government placed this report before the Chamber of Commerce, Cape Town, who, after careful consideration, replied that they were well acquainted with the conditions prevailing in England in connection with the wine trade, and that the price obtained in South Africa was better than that offered in England, and for this reason they could not see any good results would follow if they forwarded the samples. Mr. Burgoyne made a great mistake if he judged a country by its export trade only. It might interest him to know that France, the largest wine-producing country in the world, whose annual production totalled 1,250,000,000 gallons of wine per annum, only exported to all other countries of the world about 4 per cent. of its total output; while Italy, the second largest wine-producing country in the world, with a production of 700,000,000 gallons, exported even a smaller proportion. These countries also catered for their local trade, it being remembered that all countries imposed a heavy duty on wines crossing their borders. The speaker did not wish to maintain that it was not necessary to create an export trade, but nobody knew better than Mr. Burgoyne what it would cost to do so, and how little benefit the producers would receive from it. The consumers of Mr. Burgoyne's wines in this country might be surprised to hear that only about 10 to 15 per cent. of what they paid for the wine went to the producer, while more than 85 per cent. went to the advertising agencies, to the Treasury in the form of Customs duties, profits to the distributors, and other incidental expenses such as bottling and marketing. Mr. Burgoyne told them a great deal about what experts had done for Australia. Unfortunately the foreign experts tried in South Africa had proved to be hopeless failures. The only successful wine experts they had had were those of Colonial birth. Mr. Burgoyne also enlighted them considerably as to the methods and results of wine making in Australia, and, while again agreeing with him that the Australian wine growers deserved every credit for having produced a commercial type of wine, the speaker must say that its quality was not such as to induce South African growers to aim at it as a model. It was well known to all those connected with the wine trade that the South African wines, as consumed in the clubs and hotels or in private life, were of a decidedly better quality than Australian wines. This was the verdict of their own judges in England. The result of the awards at the Grocers' Exhibition of last year, when a London firm (Messrs. Westmacott & Co.) exhibited under the Colonial Section a few small lots of Cape wine which they had in stock, proved that in every case where Cape wines came in contact with Australian wines, the South African article took the superior award—that did not show ignorance or indolence. The South African wine farmers, so hardly dealt with by Mr. Burgoyne, were not wholly to blame for the class of wine they made. They only grew the grapes and sold the wine before it was ten months old to the wine dealers, who manipulated it and placed it on the market. The wine farmer was a business man; he made the class of wine which the dealer required; the latter bought what he could sell. At all events, if anybody was to blame for not having created a market in this country for South African wine it was not the wine grower, but the dealer. It was the duty of the latter to find markets and the duty of the former to produce the article demanded. To produce a very high-class wine necessitated a considerable increase in the cost of production, and there was little demand in South Africa for high-priced wines, while the market in England was well stocked with high-priced wines from the Continent of Europe with old-established brands. In conclusion, the speaker quite agreed with Mr. Burgoyne when he pointed out the great fertility of the soil in South Africa and how easy it was to produce wines, and as he had all the means at his disposal Mr. Chiappini felt sure that under such favourable conditions Mr. Burgoyne would go out to South Africa and produce large quantities of wines suitable for this market. For the last 100 years, however, they had had critics of the methods of production of wine in South Africa, all of whom had pointed out the great natural advantages which the country offered for the easy production of wine. These criticisms emanated from a class who sold their imported wares to the farmer, and who bought his products, but with few exceptions not one had been known to devote his time or put his capital into the production of wine in South Africa. What they really wanted in the South African wine trade was a Burgoyne to find a market for their wines, and the speaker could assure him that the wine farmer in South Africa would produce what he offered to buy.

Mr. M. D'Arblay Burney said he had listened with very great interest to the discussion, as he formerly occupied the position of Viticultural Expert to the Government of Victoria. In Australia they compared viticulture with their own standards, and

Hosted by Google

those standards were somewhat higher than at the Cape. He took it that the paper had no intention of decrying the product of the Cape, but was merely making a comparison from a perfectly natural standpoint. Mr. Chiappini had mentioned that the production of wine at the Cape was six million gallons. Mr. Burgoyne stated that the production of brandy in one year was 1,100,000 gallons. It took about five gallons of wine to produce one gallon of brandy. That showed that a large proportion of the wine in South Africa was made into brandy simply and solely because it was not of a quality that would find a market elsewhere. The opposite argument would very largely apply to the illustration comparing France as a wine-producing country. The remark that the very large production in France was consumed in the country would lead to the belief that the districts in France which produced wine for their own consumption were the rich districts, but it was really the countries that were able to produce a wine of such a value as to be recognised all over the world which had succeeded commercially. He should like to point out that when the Chairman visited Albury many years ago the methods then utilised were not the extremely high scientific methods at present in vogue in that district.

Professor Anderson Stuart said it was not ignorance and indolence on the part of South Africans, but the cost of labour. As Mr. Burgoyne pointed out in his paper, it cost a good deal of money to grow grapes, and, therefore, the grapes were grown on the flat alluvial land and produced a strong "must" and a strong wine. He was glad to hear the nice things Mr. Burgoyne had said about Australia, and agreed with what he said about the claret being often a kind of Burgundy. It was a great pity that European names had been adopted instead of Colonial ones. It would have been much better if the wines had been named after the districts. It would surprise many people to hear that in the neighbourhood of Sydney a very excellent champagne was produced. He had discovered by experience that the merchant was a very important person in the wine trade. If one went to the vineyard and asked for a quantity of wine, one was never sure of getting the best bargain for one's money. The merchant, however, knew his business and was able to buy a good wine because the bad wine was not going to keep. It was quite true that Colonial wine was in many cases banned. To this day there was a great deal of snobbery at the dinner table, and he himself was one of the snobs, because he thought twice before he offered his guests Colonial wine, as if he did so they would probably think he was a mean Scotchman! It required a certain amount of moral courage to give a man Colonial wine, and so long as Colonial wine was banned the production would undoubtedly be discouraged. He himself preferred Colonial wine for two reasons, first, because it was cheap, and, secondly, because he could use less of it and get the same effect. The dryness and sunshine of Australia produced a strong grape-juice which produced a strong wine. There was a third reason, the most potent of all, and that was that he was patriotic. He was interested to hear that one bottle out of twelve drunk in this country came from Australia, and also glad to know that the supply was not equal to the demand, as he would see to that when he went back to Australia.

Mr. P. J. Hannon thought the unfortunate misunderstanding that had arisen between Mr. Burgoyne and Mr. Chiappini was due to the fact that Mr. Burgoyne had not had the opportunity of consulting the latest reports from South Africa on the development of the wine industry. It was his fortune to be associated for three or four years with the wine industry in South Africa as Government officer charged with the organisation of what was known as the Co-operative Winery in South Africa. So far from the Cape farmer being at all backward in taking advantage of modern methods in making wine, he had brought himself not merely up to date, but very much more up to date than many people who were concerned with the manufacture of wine in Australia. With Mr. Burgoyne's characteristic modesty he did not say how much his own family had influenced the improvement of the Australian wine industry. When endeavouring to improve viticulture and wine making at the Cape, he tried as far as possible to get at the secret of the Burgoynes' success. Mr. Chiappini sent out to him a very large collection of Mr. Burgoyne's products, and the products of several other wine makers in Australia, and they did their best in South Africa to produce wines of similar types, but the South African wine people said that the South African wines of their own types were in every case superior to the samples received from Australia. He felt sure the meeting of Mr. Burgoyne and Mr. Chiappini would have the effect of clearing the air, and cementing the relations between Australia and South Africa in the future.

Mr. Robert Gray (Renter Warden of the Vintners' Company) said Mr. Burgoyne had omitted to mention New Zealand, from which some very excellent wines had come, and he thought New Zealand should not be omitted from the list of wine-producing countries of the Empire.

Mr. Alan H. Burgoyne, in replying, admitted that he had left out New Zealand, but he had also left out India, where he was told that they onc grew a bunch of grapes. He had said at the beginning of the paper that it was necessary to deal only with those countries which were developing the vine on a commercial basis, and he did not think New Zealand was doing that. He accepted the Chairman's reproof. He wrote the remarks on South Africa with the courage of ignorance. It was only possible when dealing with the product

of a country to judge them by commercial results. The Cape started wine making 200 years before Australia thought of it; and yet as the result of bad methods of cultivation thirty years ago, Cape wines had a bad name to-day; and it was owing to Australia carrying out the manufacture in a scientific manner from the commencement that they had swept the Cape wines off the markets of the United Kingdom. He was afraid Mr. Chiappini really did not say quite enough, because in dealing with the criticism in the paper he had overlooked the praise which was also there. He should never accuse Mr. Chiappini of being either ignorant or indolent, for his remarks were both interesting and far-reaching. He was very glad to have had the opportunity of seeing the national spirit so strongly developed, and very glad that it had not become a national conflict. With regard to the remark that the wine grower at the Cape only made what the merchant offered to buy, if the Australian wine trade had been developed on that basis there would have been no wine bought. Australia made the people buy what they ought to drink, and that was the only method of making business in these days of competition. He should have liked the discussion to have gone on, because no question had been raised that presented any difficulty in answering. It had been a pleasure to him to put forward a few details of what he thought was going to be a very great and very important industry in the near future.

Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D., said there was no question of the original country of the vine—that is, ever since the surface of this world had presented the physiographical features and conditions known to us at this day; and roughly we might identify it with the Persian provinces of Azerbaijan, Mazandaran, and Khorasan. It was from here as a centre that the cultivation of the vine and the manufacture of wine had been carried east and west into all the countries of the world, which had an average annual temperature of from 48° to 68° Fahrenheit, the summer temperature never falling below 66°, and the winter below 38°. The etymological facts that the Semitic, that is, the Babylonian, Assyrian, Hebrew, and Arabic names of the vine were radically one and the same, and that the European names for wine were all modifications of its Aramæan name, were of themselves a strong indication that Mazandaran was the primæval habitat of the vine, and Armenia the earliest notable seat of the brewing of wine, and market of its commerce. The Biblical myth of the drunkenness of Noah, Genesis ix. 21–5, and the Iranian myth of the accidental discovery of wine by the wife of "King Jamshid" of the "Peshdadian Dynasty" of Persia, of which Mr. Burgoyne gave, at the beginning of his lecture, a local variant,—were in their vague, epical way, a confirmation of the inferences he had ventured to draw from the derivations of the words vine and wine. The Queen was fond of grapes; she forgot for a while some she had left in a jar; and when she next looked into it, finding they had all fermented, and turned to a musty liquid, curiously tasting which, and becoming intoxicated, she tempted King Jamshid to drink some; and he also becoming intoxicated, they called the accidental brew *Zehr-i-Kush*, "the Poison of Delight," the Persian laudatory phrase in praise of wine from "B.C. 3209" until now. These myths, taken together, implied also the immense antiquity of the cultivation of the vine, and the manufacture of wine; an implication fully supported by more conclusive historical evidences. It was demonstrable from the monuments that wine was in use in Egypt from at least B.C. 3000. The immemorial wealth of Palestine in the vine was strikingly shown by the passage in Genesis xlix. 11, 12, in which, describing the prosperity of Judah, it was said—"He washed his garments in wine, and his clothes in the blood of grapes; his eyes shall be red with wine": while the estimation in which the vine and wine were held in Israel was well illustrated by the parable in Judges ix. 8-16, of the Vine being asked to be "King of the Trees," and answering—"Should I leave my wine, which cheereth God and man, and go to be promoted over the Trees?" This appreciation of wine, as one of the best of the gifts of God to man, continued with Israel to the end, as was to be seen in the advice of St. Paul to Timothy, 1 Timothy v. 23—"Drink no longer water, but take a little wine, for thy stomach's sake, and thine often infirmities." The wines of Helbon, and Lebanon, and Zeeb were in repute in all the countries surrounding Palestine; and the fames of their names gave a fragrance and a flavour to these antique brands (the first two of them he once procured from Syria), which they would otherwise lack for those whose "nose" and "taste" had been sophisticated by generations of intimacy with the vintages of France, and Spain, and Portugal. Wine was used in the religious ritual of Israel; but the priests might not drink of it while actually engaged in the service of the altar (Leviticus x. 9). This enthusiasm of Israel for wine did not blind them to the evils of the abuse of its enjoyment, only it was sagaciously recognised that gluttony was no less pernicious than drunkenness,—"the bread of wickedness" than "the wine of violence." Homer's references to wine were as instructive and interesting as those of the Bible, and seemed inspired by a similar spirit. In the Iliad, i. 462, he referred to "sparkling wine" poured on the roasting joints of victims offered to the Phœbus Apollo; iii. 246, to "joyous wine . . . in a goat's skin"; iv. 259, to "cups of dark red wine,"—and 346, to cups of sweet wine; in xi. 639 (and Odyssey x. 234–5), to Pramnian wine: and in the Odyssey, ii. 346, to "old sweet wine, divine drink,"—and 350 to "sweet wine in casks, more luscious than all the rest [in Penelope's "cellar"] save that reserved against the return of Ulysses"; iv. 622, to "heartening wine"; v. 165, to "red wine giving strength,"—and 265, to "a skin of black wine"; ix. 163, and following, to men "feasting all the day to sun-down on roasted meats, and sweet wine,"—196, to "a goat skin of

Hosted by Google

black wine,"—and 205, to "wine in 12 casks . . . divine wine," which poured out to drink was mixed with "twenty measures of water, raising a sweet fragrance from the cup divine." Returning to the Iliad, vi. 264 and following, we found Hector adjuring Hecuba :—"Bring me no exhilarating wine, revered mother, lest it unsteady me, and I fail in prowess." But the "Natural History" of Pliny was the inspiring and splendid storehouse, "the classical place," of the knowledge of the cultivation of the vine, and the manufacture of wine possessed by the ancients; and inexhaustible so far as Greece and Italy were concerned. Beside other incidental notices, the whole of Book xiv. was given up to the subject; and every one of us practically engaged in, or responsibly connected with viticulture and vinifacture ought to know the book as intimately and instinctively as his A B C. Pliny himself protested against the impatience of such men of the experience of past generations in their own trade—the very impatience shown by the so self-called "practical men" of our present day towards classical studies. He would make note of but a few of the facts recorded by Pliny in Book xiv.; and it would be no reflection on us if after an interval of just 2,000 years we found those which he thought trivial the most significant. After, in Chapter 2 (1), stating, as quoted by Mr. Burgoyne, that the staircase of the temple of Diana at Ephesus was constructed of vine-wood, in Chapter 7 (3), he said of wine drinking, "Nothing is more healthful in moderation, nothing more harmful in immoderation"; in 8 (6), he enumerated fifty varieties of generous wines; in 9 (7), thirty-eight of foreign wines; in 10 (8), seven of salted wines; in 11 (9), eighteen of sweet wines; in 12 (10), three of second class ["deuteria"]; in 19 (16), sixty-six of artifical wines, including cyder; in 22 (18), twelve "with miraculous power," recalling the "wine of astonishment" of Psalms lx. 3, A.V. ["deadly wine" of the Psalter, and "wine of staggering," R.V.]; in 23 (19), beginning with the observation that [as in India of the Hindus, so in Greece and Rome] life is based on religion ["religione vita constat"], he tells us that it was held improper by the Romans to offer to the gods any wines derived from an unpruned vine, or one struck by lightning, etc., or Greek wines, because of their being diluted with water; 23 (22) on drunkenness was the most powerful, because the most temperate "Temperance Tract" ever indicted; and it was an apt example of how much we lost from our system of classical education being too exclusively restricted to the perfectioning of scholarship, and literary culture, and political wisdom, to the neglect of the study of the industrial knowledge and the economic arts of the ancient Greeks and the Romans, that our advocates of temperance should never have reproduced this chapter from Pliny, the sound common-sense of which was as impressive as its simple eloquence. In Book xxiii. he again treated voluminously of the medicinal virtues of wine, and quoted the popular proverb, "Wisdom is obscured by wine"—"Sapientiam vino obumbrari." The other ancient proverb of wine, "In vino veritas," was first quoted by Plato—Οἶνος ἀληθής ἐστι. All that is classical of antiquity being always modern, to the latest modernity, he now quite naturally passed from Pliny to the fourth paper by Sir Henry Trueman Wood on "The History of the Royal Society of Arts," dealing with the subject of "The Society and the Colonies," published in our *Journal* of September 29th last, because, with reference to what Mr. Burgoyne had said of John McArthur, he wished to draw attention to the fact that the Society awarded him a gold medal for his first importations of wool into this country, and another to Messrs. Starkey, Buckley & Co., of Huddersfield, for making some of it up into cloth; and they awarded a second gold medal to John McArthur in 1824, and also a silver medal to his nephew Hannibal "for the next greatest quantity of fine wool" received from the Antipodes; and there could be no doubt that, as Sir Henry Wood said, this prompt and decisive action of our Society, nearly one hundred years ago, "helped considerably in making known the (then) new and important source of supply (of wool) thus opened up" to the United Kingdom by "the Father of New South Wales." Mr. Burgoyne would also be gratified in hearing that, as stated in the aforesaid paper, this Society in 1822 offered a gold medal for "the finest wine, not less than twenty gallons, of good marketable quality, made from the produce of vineyards in New South Wales"; and in 1823 a silver medal was presented to Mr. Gregory Blaxland for wine from his vineyard at Paramatta; and in 1828 the gold one was presented to him for a pipe of wine produced on his vineyard in 1827. These were only two examples of the way in which the Royal Society of Arts has ever kept on the alert to encourage the incipient industries of our wonderful Colonies, and of the discrimination shewn by the Society in so doing; and the Colonies owed the Society a substantial measure of gratitude for this our persistent and patriotic attitude towards them. He must back Mr. Burgoyne in his criticism of the Cape wines, and he was glad of the honest indignation it aroused in Mr. du Plessis Chiappini. Mr. Burgoyne was evidently thoroughly well informed on the history of Cape wines, and could recall the fact that when the duty on Cape wines was only 2*s.* 11½*d.* per gallon, compared with 5*s.* 6*d.* on all other wines, the Cape wines were worse than ever; and that even "Constantia," naturally one of the finest wines in the world, was degraded and depraved by the fiscal favour then shewn by us toward Cape wines. After to-night he would hope that the Cape wines would be worked up to the same high standards of quality as the Australian wines, and that Mr. du Plessis Chiappini, and even he himself, might live long enough to find that between importations from the Cape, and from Australia, we should in this country be drinking, not one bottle only of Colonial wines out of every twelve we import from over seas, but the whole dozen, all Colonial, for there was

Hosted by Google

no finer wine produced in the world to-day than the Australian. He did not speak of bookish knowledge only, but of practical, personal experience. Mr. Brudenell Carter, the eminent oculist, founded in 1871 the International Wine Society of London, and made him an original member of its committee, because he was found to have an infallible "nose" and "taste" for port wine and brandy, and for about thirty years he never missed the monthly meeting for tasting wines; and they all gave particular attention to our Colonial wines, including those of California, for America was, for the present, our greatest Colony; and he must say that Cape "Constantia," when honourably brewed, and the wines of Australia and of California, in all the essential virtues of wine, were not to be beaten by anything —"From humble Port to imperial Tokay"— that came to us from Europe; although some prejudices still remained in favour of flavours in wines which, one or another of them, we had been drinking for centuries. Throughout all time, and all countries, the witness of sound wines was to be sought in their odour, and flavour, their clarity, and colour; and all fine wines should be strong of constitution, beautiful to behold, and fragrant, fresh, and frisking:—

"Vina probantur odore, sapore, nitore, colore:
Si bona vina cupis hæc quinque probantur in illis,—
Fortia, formosa, fragrantia, frigida, frisca."

He most cordially moved the vote of thanks to Mr. Burgoyne for his paper, which had proved of two-fold merit, in its own excellence, and in its having provoked a discussion, full of reality, and of the best omen for the future of our Colonial wines. Votes of thanks to the chairmen at these meetings were not proposed, but as the only member of the Council of the Society present, he must be allowed to express their gratitude to the Right Honourable Sir Walter F. Hely-Hutchinson for taking the chair that afternoon, his occupation of it having so greatly contributed to the cordiality and marked success of the meeting.

THE HON. JOHN GREELEY JENKINS (ex-Prime Minister of South Australia), in seconding the motion, said he came from a little State where there were only 400,000 people, but where between three and four million gallons of wine were manufactured. A great deal of credit was due to the firm of Messrs. Burgoyne & Co. for the introduction and improvement of Australian wines, because after all to build up a business it was necessary to put good stuff on the market. Mr. Burgoyne spoke of the superiority of Australian wine, and Mr. Chiappini had dealt with the superiority of Cape wine. It was difficult to judge between them, and perhaps it would have been better if they had brought a dozen bottles and submitted them to the meeting, which might have acted as a jury and settled the matter! In dealing with the production of wine in different parts of the Empire, the British Government, being a strong Free Trade Government, would never think of assisting Australia by a duty, but he had pointed out to some members of the present Cabinet that in the interests of free trade the duty on Australian, South African, and other wines, might be reduced without sacrificing any high moral principles in any way whatever.

THE NEW INDIAN PROVINCES.

The recent introduction of the Government of India Bill, which contains the machinery necessary for carrying out the policy announced at the Delhi Durbar, is concentrating public attention and some criticism on political changes in India, which would doubtless have elicited more attention and discussion had their importance not been overshadowed at the time by the overwhelming personal interest of the King's visit to India. Apart from the momentous change of capital from Calcutta to Delhi, it may be recalled that three new Provinces, or divisions of considerable extent, were created, viz., (1) a new Governorship-in-Council of Bengal, re-uniting the five Bengali-speaking divisions, entitled the Presidency, Burdwan, Dacca, Rajshahi and Chittagong divisions, with an approximate total area of 70,000 square miles and a population of about 42 million; (2) a Lieutenant-Governorship-in-Council, to consist of Behar, Chota Nagpur, and Orissa, with a legislative council and a capital at Patna, the area of this Province being approximately 113,000 square miles, and the population about 35 million; and (3) the restoration of the Chief Commissionership of Assam, the area of which will be 56,000 square miles, with a population of about 5,000,000.

In order to appreciate the importance of these new administration divisions, it is desirable to call to mind that they supersede a very different state of things which has been in existence since 1905, when the reconstruction of the former Provinces of Bengal and Assam, popularly described as the "Partition of Bengal," was carried out. This again, it may be useful to recall, had consisted in the formation of a new Province, Eastern Bengal and Assam, the main object of that change being to reduce the area of Bengal, up to then 189,837 square miles, with a population of 78½ millions, to 141,580 square miles, with a population of 54 millions. Although the reduction in size of the former unwieldy Province had been rendered imperatively necessary, and though the relief afforded to the overworked administration of Bengal during the six years that the so-called "partition" has been in force, has proved considerable, the Government of India have frankly admitted that the partition aroused "violent hostility" amongst the Bengalis, and this is avowedly the mainspring of the movement which has resulted in the formation of the new Provinces. The Governor-in-Council of Bengal will, unlike his predecessors, have the advantage of a second capital at Dacca, with all the conveniences of ordinary provincial head-quarters, and thus be enabled to keep in close

Hosted by Google

touch with Mohammedan sentiments and interests. With regard to the Lieutenant-Governorship-in-Council for Behar, Chota Nagpur, and Orissa, one of the chief considerations has been the desirableness of giving the Hindi-speaking people hitherto included in Bengal a separate administration. Regarding the cost of the new scheme, no attempt at an accurate estimate at the time of the Durbar was possible, because the Viceroy purposely avoided making inquiries, lest the proposals in contemplation should be prematurely disclosed. The confident hope, however, is entertained that the cost of the transfer of the capital cannot possibly exceed four millions sterling, a sum which would include the three years' interest on capital which would have to be paid till necessary works and buildings were completed. On the other hand, there would be valuable sets-off in the sale of Government land and buildings no longer required at Calcutta, and reduction in the current expenditure involved in the annual move to and from Simla, which is, of course, far nearer to Delhi than to Calcutta. The actual railway journey from Calcutta to Simla takes forty-two hours, while Delhi can be reached from Simla in fourteen hours.

FOURTH INTERNATIONAL ART CONGRESS, DRESDEN, 1912.

An International Congress for the Development of Drawing and Art Teaching and their Application to Industries will be held in Dresden from August 12th to 17th. It is concerned with all branches appertaining to the teaching of drawing, from the elementary school to the practice of fine and applied art in institutions devoted to the technical training of students.

The previous congress was held four years ago in London, and the magnitude of the exhibition, arranged in a portion of the Victoria and Albert Museum, showed the public generally, and art teachers in particular, that the subject promised to become more vital in the future, and its educational aims were more than hinted at.

At Dresden, some of the galleries erected for the International Hygiene Exhibition last year are to be devoted to another exhibition, where it is hoped that further progress will be demonstrated. In order to concentrate the general show upon particular points, it has been resolved to exhibit more definitely the work in secondary and trade schools, and in technical schools and schools of art.

The United States of America will send a large exhibit, demonstrating the entire art scheme as carried out in selected towns of different areas and having varied industries.

The Germans will show the organisation and results of their trade and technical schools, while Austria will do the same kind of thing, but upon a smaller scale.

The Board of Education, the Scotch Education Department, the Department of Agriculture and Technical Instruction for Ireland, are all contributing both exhibits and delegates, thus representing the British Government. The London County Council will be amply represented, while collections from provincial schools of art and from English secondary schools have been gathered together by the National Society of Art Masters and the Art Teachers' Guild. Welsh secondary art education is represented, owing to the strenuous efforts of an enthusiastic teacher in Swansea. Last, but by no means least, Mr. Ebenezer Cooke, the veteran teacher, who, in his enthusiasm and unselfishness has imbued a vital spirit in the teaching of drawing both here and abroad, has been specially invited to contribute work.

The papers to be read will also be more concentrated in character. The subject of "Lettering" will be treated by Mr. Edward Johnston, whose paper will be illustrated by a demonstration. Mr. J. T. Ewen, H.M.I., will speak of the progress made in Scotland, by which certain art schools are linked up with the universities, and the whole status of the art student put upon a broader and higher basis.

Delegates are being sent from many county councils and educational bodies, and it is hoped that friendly intercourse with colleagues coming from all parts of the world will help greatly to make all see that which makes for vitality, and for true education of the mind, through the hand and eye, as well as the points in the technical training of students.

A large party of teachers has been organised to start on the August Bank Holiday, in order to spend the journey profitably and pleasantly, by visiting Hanover, Hildesheim, and Brunswick, on the way, and thus, by seeing a little of Germany itself, to become more receptive of its aims and ideals.

HOME-GROWN WHEAT.

In a paper on "Home-Grown Wheat," recently read before the Farmers' Club, Mr. A. E. Humphries said the chief hope for wheat-growing in this country rested upon cheapening production, increasing the yield per acre, and improving the milling quality; there was no reason to expect great alterations in value in either direction. British and Irish farmers might well be proud of their existing yields, but the highest possible had not yet been reached. No one variety of wheat was suitable, nor were we likely to provide one suitable, for all the varying sets of natural conditions existing even in our small islands, and a detailed study of each set and the provision for it of a variety, or varieties, in the highest degree suitable to it, was likely to raise our already high yields. The diminution or eradication of susceptibility to certain plant diseases was also an important development in modern science likely to increase substantially the average yield per acre.

Another method of increasing the profit of wheat-growing was to improve the relative value of the product. The relatively low value of

Hosted by Google

English wheat was due to two main causes. The one of lesser importance was the high percentage of water, which, however, was not a characteristic of the wheat of last year's growth. The great point was the inferior quality of British wheat. The inherent fault was that it was nondescript according to current standards of excellence; it had no outstanding merit for bread-making purposes. Mr. Humphries answered the question—Can we produce in the United Kingdom wheats possessing the necessary qualities on an average of years?—in the affirmative. On that point doubt no longer existed. But could such varieties be made to yield a sufficiently large financial return to the grower? —that was the problem which the Home-Grown Wheat Committee of the National Association of Millers set out to solve, and they were confident that the answer was in the affirmative.

He proceeded to describe the work of the committee and the Cambridge experiments in raising Mendelian wheats. From the results already achieved with Burgoyne's Fife he considered that the problem of raising a wheat combining milling quality and prolificacy was in a fair way to being solved.

THE CONSUMPTION OF FOOD IN PARIS, 1911.

The following statistics, lately published by the Prefecture of Police, which controls the markets of Paris, gives the quantities of some of the principal articles of food brought to the Halles Centrales last year as compared with those of the previous year:—

	1910.		1911.	
	Metric tons.	English tons.	Metric tons.	English tons.
Meat	56,797	55,902	54,763	53,900
Poultry and game	23,607	23,235	22,255	21,904
Fruit and vegetables	46,157	45,430	59,535	58,597
Butter	15,076	14,838	13,921	13,702
Cheese	14,605	14,375	12,828	12,626
Number of eggs	312,524,000		300,868,000	
Number of vehicles engaged in bringing produce to market	324,000		327,000	

Although a considerable falling-off is noticeable in the quantities of meat, butter, cheese and eggs brought to market last year as compared with those of 1910, the supply of vegetables was considerably larger. The amounts realised by the sales of produce in 1911 were also greater.

THE MUSEUM OF OCEANOGRAPHY AT MONACO.

The Museum of Oceanography, which owes its existence to the Prince of Monaco, Albert I., is certainly one of the most important institutions of the kind connected with this wide field of study and research. Founded in 1899 to contain the rich collections made by the Prince during his numerous scientific voyages in his yachts, the "Princess Alice" and the "Hirondelle," since 1885, the aims of the institution have been extended, and now include all that relates to oceanographic knowledge and the advancement of marine biological studies.

The museum at Monaco is built on the side of a cliff, overlooking the sea, at the east end of the beautiful gardens of St. Martin. The foundations of the building are carried down to the level of the sea, some 53 metres (174 ft.), below the main entrance situated in the Avenue St. Martin. The building is 100 metres (328 ft.) in length. The ground floor, besides a fine entrance and reception-room, contains a grand hall, suitable for conferences, lectures, etc., which occupies the entire west wing, whilst the east wing contains the collection of marine animals and plants arranged in their zoological or botanical order. The centre of this hall is occupied by the skeletons of a Greenland whale (*Balaena mysticetus*), 20 metres long (66 ft. 6 ins.), brought in one of the expeditions of the Prince from Spitzbergen, and a cachalot, or sperm whale (*Physeter macrocephalus*), 16 metres (52 ft. 6 ins.) long. There are also fine specimens of the seal, walrus, and other marine animals, including a manatee (a cetaceous herbivorous mammal) from the River Amazon. The collection of fish, molluscs, crustaceans, and echinoderms, is very complete. Amongst the crustaceans may be noticed a specimen of the *Macrocheira Kempferi*, an enormous spider-like creature from Japan. Four expeditions to the Polar Seas, as far as 80° N. lat. furnished specimens of the flora and fauna of those regions to compare with those of the Mediterranean and North Atlantic Ocean, and more especially with the animal and plant life of the Azores, Bay of Biscay, the coasts of Portugal and Morocco.

Many specimens were brought up from great depths, in some cases even from 6,000 metres (3,560 fathoms, about 3¾ miles) below the surface. Living specimens of the *Centrophorus* have been obtained in the Mediterranean at a depth of 2,700 metres (over 1,400 fathoms).

On the upper floor are shown nets and appliances of every description used for fishing, traps for catching animals and fish, many of which were designed by the Prince himself, or by his assistants. At the top of the staircase is the little whale boat belonging to the yacht; models of the two yachts named "Princess Alice," both of which were built by Messrs. Green, of Blackwall; and a model of the "Hirondelle," built at La

Hosted by Google

Seyne, near Toulon. The collection of nets is very complete, and includes the ordinary deep-sea nets, Hensen's nets, vertical nets with large meshes, seine nets, and the fine nets used for collecting the "plankton"* from the surface of the water whilst the ship is in motion; trawl nets and apparatus for trawling and gear of every description used in trawling. In some cases trawling was carried on to a depth of 5,310 metres (3,218 fathoms). Harpoons, guns for throwing harpoons and other appliances for the capture of whales, are also shown.

The collection of instruments used by the Prince in his investigations is also very interesting and numerous. It includes a variety of floats and apparatus used for determining the direction and measuring the velocity of ocean currents at different depths; sounding machines of various systems, and apparatus for bathymetrical research of every description. Specimens of rock, sand, clay, pebbles, and even the casts of marine worms, which have been brought up from the bottom of the ocean in various places, are also shown. The bottles used for taking samples, and automatically registering the temperature of the water at different depths, apparatus for determining the chemical composition and density of the water, as well as the instrument used for ascertaining and studying the penetration of light to different depths, and other instruments, find a place in the museum.

The aquarium is situated on the lower of the two floors of the basement, and occupies the east wing of the building. The numerous tanks vary in size from 1 metre (3 ft. 3 ins.) to 6 metres (19 ft. 6 ins.) in length, are well stocked with a variety of fish of various kinds—crabs, lobsters, star fish, an octopus, and a quantity of sea anemones. A tank of larger dimensions contains several large conger eels. In one corner of the building is a large shallow tank, containing two sea tortoises, brought from the Azores in 1896, one of which has increased in weight from 3 kilogs. to 40 kilogs. ($6\frac{3}{4}$ lbs. to 88 lbs.) in the meanwhile. A small aquarium contains some lively specimens of the sea-horse, a curious little creature, somewhat resembling the Knight in a set of chessmen.

The water to supply the aquarium is raised from the sea by two pumps, driven by electricity, to a height of 64 metres (210 ft.), into a tank placed near the top of the building. It is aërated before entering the aquarium by an ingenious arrangement on the principle of the injector used for steam boilers.

The west wing of this floor contains a well-equipped naturalist's workshop, with all appliances and tools suitable for mounting large specimens.

On the upper floor of this basement are the biological laboratories, workrooms, photographic studios, with dark rooms, etc., and other laboratories for research of various kinds. Here, too, are the library, offices, and store-rooms.

The museum also contains an interesting series of charts by which the relative distribution of the principal forms of life in the ocean is graphically displayed; for instance, the proportion of land to water on the globe, etc.

The chemical composition of sea-water in different parts of the globe is also illustrated graphically, whilst the different proportions of sea salt contained in the water of the Baltic, Red Sea, Mediterranean, and Atlantic Ocean, is brought prominently to mind by a series of glass jars containing salt, as compared with a cube measuring one metre.

* "Plankton," name given to the heterogeneous collection of minute and microscopic animals and plants found floating in the upper layers of the sea.

CORRESPONDENCE.

THE MANUFACTURE OF NITRATES FROM THE ATMOSPHERE.

I have read Mr. Ernest Kilburn Scott's interesting paper in the *Journal of the Royal Society of Arts* of May 17th.

On page 654 the contracts for machinery, etc., of the Rjukanfos installation are given. It is a most significant fact that not a single contract was given to a British firm.

Can British firms not compete, or can they not manufacture the up-to-date plant required? Or is it the frequent case—"no Britishers need apply"?

R. HOWARD KRAUSE.

OBITUARY.

SIR JULIUS CHARLES WERNHER, BART.—Sir Julius Wernher died at his residence, Bath House, Piccadilly, on the 21st inst. Born at Darmstadt in 1850, he was educated at Frankfort-on-the-Main. In 1870 he came to London as a clerk in an Anglo-German firm, but on the outbreak of the Franco-German War he returned to his native country and served as a trooper in a dragoon regiment, being present at the fall of Paris. After the close of the war he went out to South Africa with Mr. Jules Porges, and remained for nearly ten years at Kimberley. In 1880 he returned to London as the English partner of the firm of Porges and Wernher; but four years later he went back for a time to Kimberley, and it was then that he formed his connection with Mr. Alfred Beit. In 1888 Rhodes and Beit brought about the amalgamation of the diamond mines at Kimberley, as a result of which Wernher became a life governor of the De Beers Corporation. In addition to this, he was a director of the Rand Mines, and chairman of the Central Mining and Investment Corporation.

Mr. Wernher was created a baronet in 1905. He took a deep interest in education, and served on Lord Haldane's Committee on the Royal College of

Hosted by Google

Science and Royal School of Mines, whose report led to the establishment by Royal Charter of the Imperial College of Science and Technology. Last year he was awarded the gold medal of the Institution of Mining and Metallurgy in recognition of his "great personal services to the advancement of technological education." A short time before he had given £10,000 to the National Physical Laboratory for the extension of its metallurgical department; and he presented a sum of about a quarter of a million pounds sterling to assist in endowing the new teaching university for the whole of South Africa, which it is hoped will be established at Cape Town.

Sir Julius Wernher became a member of the Royal Society of Arts in 1899.

NOTES ON BOOKS.

Lectures on Cellulose. By C. F. Cross, F.I.C. London: The Institute of Chemistry of Great Britain and Ireland. Price to persons not connected with the Institute, 2*s.* 6*d.*

The lectures form the second course delivered under the scheme recently instituted by the Council of the Institute of Chemistry, under which Fellows with special knowledge and experience in certain branches of work give lectures for the benefit of young chemists and advanced students who are qualifying themselves for industrial appointments. The first course, "Lectures on Cement," by Mr. Bertram Blount, was noticed in these columns last month.

As Mr. Cross points out in introducing his subject, the word cellulose, from the industrial point of view, covers an enormous field, including cotton, hemp, linen, jute, ropes, twine, straw, and timber, and representing an annual gross figure of not less than two hundred million pounds sterling; and if we add coal, which is "certainly derived in the main from cellulose by processes of regulated destruction," we must increase this gigantic total by another hundred and fifty millions. It is obviously impossible to deal with all these industries in so short a space, and accordingly, in his first lecture, Mr. Cross discusses a few prominent examples of industrial problems as illustrations of principles, and in the second he takes certain types of carbohydrate colloids, such as starch, hemi-celluloses from seed-endosperms, and cellulose hydrates, concluding with some interesting and suggestive remarks on the enormous waste which at present goes on in certain cellulose products, such as cornstalks, rice-straw, megasse, sawdust, etc.

Textile Design. Pure and Applied. By Thomas Woodhouse and Thomas Milne. London: Macmillan & Co., Ltd. 10*s.*

A cursory perusal of this well-produced, solid volume, containing more than 500 pages, illustrated with over 300 carefully worked-out diagrams, is calculated to enhance the very general impress[illegible] of the bewildering technicalities of the weaver's art. To the general reader, or indeed to any student not conversant with the mechanisms an[illegible] methods made use of in modern weaving, a car[illegible] study of the work would be very wearisome and would but slightly elucidate the mystery, for the reason that the authors have, in so many cases, omitted to explain the meaning of the technical terms made use of, which are often of quite local signification, and the relation of certain procedures described to the machines on which they are to be carried out.

In their preface the authors mention that the present volume is Part III. of a formerly published serial work which dealt with the whole subject of jute and linen weaving. It is probable, therefore, that many of the points which are obscure in the book before us would be elucidated by reference to the former parts. But explanatory notes and a glossary of technical terms would have readily obviated the difficulty. No technical work, indeed, can be considered complete or satisfactory without such aids to the reader's understanding.

The students to whom this work on textile design will mostly appeal, and should prove to be of the greatest use, are those employed in the design department of textile manufactories of all kinds. For, as the writers truly say on page three of the introductory chapter: "Apart altogether from the requirements which are demanded of a designer in any particular branch of textile industry, it is, in his own and his employer's interest, very desirable that he should study widely the different types of cloth structure. Ideas spring from many sources, and no opportunity should be neglected of becoming conversant with the vari[illegible]us sides of one's occupation."

The most interesting and important portion of the book, about one-fifth of the whole, is that whi[illegible] deals with cloth structure, or the actual in[illegible]lacement of warp and weft in all their variatio[illegible] This is very thoroughly explained and illustra[illegible] by means of a great number of clear and we[illegible] designed diagrams. In many cases the effect [illegible] the various twills, satins, and other ties, or interlacements, is shown by half-tone blocks made from photographs of actual cloth, in addition to the drafts on ruled paper.

Chapters v. to viii., and chapter x., are devoted to a description of the forms and peculiarities of small patterns, which can be woven without the u[illegible] of the Jacquard machine. These go by the name of *Spiders*, *Herring-Bones*, *Diamonds*, *Diape[illegible]* *Dices*, and *Spots*. Full directions for working [illegible] the designs for these, and entering the w[illegible] threads in the harness of the loom in the pr[illegible] order to weave them, are given, as well as p[illegible] graphs of their finished effect in the woven cloth[illegible]

Damask weaving, which forms the subje[illegible] matter of chapter ix., is somewhat inadequate[illegible] described, although it is, perhaps, the most inte[illegible] esting and perfect of all pattern-weaving. Th[illegible] general principles on which it is based are bare[illegible]

alluded to, whilst many unimportant details in the working out of particular designs are given in full. From an artistic point of view, too, the examples [illegible]design given for damask weaving leave much to be desired, although it may certainly be conceded that they are types of ornamentation which are in common use.

The chapters xi. to xv., on compound fabrics—that is, fabrics in which two or more warps or wefts are used—are clearly written and well illustrated. It is duly and correctly noted that warp effects are more economical in production, and therefore more suitable for weaving by power, than effects of weft. It is therefore only to be expected that warp effects are more used in modern weaving, whilst weft effects, which require more personal attention by the weaver, characterised ancient textiles.

Two chapters are next devoted to an explanation of double and treble cloth-weaving, both plain and figured. Some of the diagrams illustrating these compound fabrics are extremely well constructed and clearly drawn. Particularly instructive are such diagrams as that on page 328, with its analysis on the previous page.

In the last portion of the work, chapters xviii. to xxv., the technique of both cut and uncut pile machine weaving is treated of, as well as machine carpet-weaving and the imitation of elaborate brocades, which are at the present time so much in demand.

Apart from its usefulness to the textile designer, the whole work is interesting to the student of historic weaving, showing, as it does most clearly, that little that is new and original in the construction of cloth, either plain or ornamental, has been devised in modern times. Most of the fabrics figured in this volume are only counterparts of [t]hose made by the hand-loom weavers of Renais[sa]nce or mediæval Europe, or even of ancient [P]ersia, India, and China.

[P]RACTICAL LESSONS IN BOOK-KEEPING. By Thomas Chalice Jackson, B.A., LL.B. Sixth Impression. (Fourth Edition.) London: W. B. Clive. 3*s*. 6*d*.

Book-keeping is a science that continually progresses, the student of to-day being expected to have some knowledge of its application to such subjects as partnership law, income tax, joint-stock company accounts; and great progress has been made since 1899, the year in which the first edition [o]f this work appeared. Of course, the more [e]lementary portion, dealing with the theory of [bo]ok-keeping, remains more or less as it was; but [th]e latter part of the text-book (pp. 145–367), [tre]ating of the applications of modern methods generally, is entirely new.

Mr. Jackson states in his preface that in the metropolitan area alone approximately 25,000 students—usually from fifteen to twenty-one years of age, and mainly engaged in commercial pursuits—enrol themselves in evening classes for tuition in book-keeping. This text-book, which is written on very practical lines, is designed to meet the needs of such candidates, and the fact that it has now reached its sixth impression is sound evidence of its popularity.

THE APPLICATION OF HYPERBOLIC FUNCTIONS TO ELECTRICAL ENGINEERING PROBLEMS. By Professor A. E. Kennelly, M.A., D.Sc. London: University of London Press. 6*s*. net.

Professor Kennelly's book has the most useful merit of lucidity. It covers the same ground as a series of lectures given by the author last year for the University of London at the Institution of Electrical Engineers. As he states in his preface, he has two central ideas. The first is that the theories of continuous currents and alternating currents are essentially the same, and continuous current formulæ for potential, current, resistance, and power, may be applied to alternating-current circuits by the substitution of complex numbers for real numbers. In one of the appendices he deals with a case where this does not appear to apply. In an electro-magnetic receiving instrument employed on a long alternating-current circuit, the formula for the force is not obtained from the corresponding continuous current formula; for the force in this case is essentially "real." The second idea referred to is that there is a proper analogy between circular and hyperbolic trigonometry, giving the notion of the "hyperbolic angle," which is of so great importance in much of the theory of electric engineering. A series of appendices give explanations of some of the points which require further elucidation, and add to the value of the book. The reader who is previously unacquainted with hyperbolic functions, will find there, amongst other things, enough information to enable him to follow the use of these functions throughout the book.

In more than one place Professor Kennelly indicates directions in which further investigations might very profitably be made. We cannot help thinking that this is a book which will stimulate research.

GENERAL NOTES.

THE OLIVE-OIL PRODUCTION OF SOUTHERN ITALY.—The manufacture of olive oil is one of the most important industries of southern Italy, and particularly in the region known as Apulia, of which Bari is the port of export. Fifty years ago the greater part of the yield consisted of common oil: now nearly the whole can be used for edible purposes, and the quality obtained is not inferior to other well-known Italian oils that have successfully been introduced into foreign markets. The area under olives in Apulia is estimated at about 520,000 acres, with an average production of about 60,000 tons of oil. The quantities of olive oil exported to the principal countries in 1910 were as

Hosted by Google

follows, in tons. France, 1,691; Great Britain, 810; Austria-Hungary, 615; United States, 493; Germany, 215; Portugal, 155; Egypt, 155; and Argentina, 100. An extensive branch of the olive-oil industry is the manufacture of sulphur oil (soap stock), which is produced by special treatment with carbon bisulphide of the "sansa," or olive refuse, remaining in the crusher after repeated extractions of oil. Several large soap-stock factories are in operation, and the quantity exported from Bari during 1910 amounted to 6,025 tons, of which 2,668 tons were shipped to the United States.

SERVIAN FRUIT CULTURE.—The principal fruit cultivated in Servia is the plum, and the total area under cultivation in 1910 was 380,000 acres. Only a small portion of the plum crop is exported in fresh condition. The largest portion is transformed into dried plums (prunes), or into a species of marmalade without the addition of sugar, known in Servia as "pekmez." The inferior plums are utilised for making brandy. The plum-drying industry is extensive and remunerative, the Servian prunes, owing to their fine aroma, being in demand throughout Europe. The average annual quantity of prunes exported from Servia during the past ten years was 32,665 tons. Other fruits extensively cultivated are apples and pears. Apples are exported in considerable quantities. The average annual apple yield for the past ten years was 38,000 tons.

THE TUNNY FISHERIES OF SICILY.—The tunny fisheries of Sicily, some forty in number, are located along the northern coast of the island from Trapani to Messina. The fish are caught in May and June, and the quantity canned annually varies from 15,000 to 40,000 boxes of 80 kilogrammes (kilogramme = 2·2 pounds) each. The tins used hold from one-fourth of a kilogramme to twenty kilogrammes. From the refuse of the canneries about 10,000 kilogrammes of tunny oil are extracted, the average price for the oil being about £2 per 100 kilogrammes. This is shipped to Genoa, whence it is sold to firms in northern Italy, or exported to foreign countries for use in the manufacture of chemical products. To extract the oil, the refuse is boiled from twenty-four to forty-eight hours, and then passed through metal presses similar to those used in olive-oil establishments. The presses are of Italian make. The pressed-fish residue is called "bagamo," and the entire output, which is estimated at 400 tons annually, is used in Sicily as a fertiliser.

A PROPOSED NEW INDUSTRY IN MALAYSIA.—It has been proposed to start a small export trade in Malaysia in shark's-liver oil. This oil is refined in Europe, and sold as cod-liver oil. In October, the ocean sharks come into the lagoons, between the barrier reef and the atolls, to pair. At this time they can be speared in large numbers by people skilled in catching them. There are several species of these sharks, and they ordinarily run from seven to fifteen feet in length. The girth of an ordinary shark is the same as its length, and an eleven-foot shark would be eleven feet round the body. The liver of a shark of this size gives about five gallons of oil. The oil brings £15 a ton. The sharks are found in pairs, and the harpooners try to kill the male first, in which case they are able also to spear the female, as it does not desert its mate.

CULTURE OF SEA-ISLAND COTTON IN CUBA.—A company at Artemisa, Pinar del Rio Province, Cuba, has for the past three years been carrying on a series of experiments in the culture of sea-island cotton. The chief desire was to demonstrate whether or not cotton grown in Cuba under certain conditions of culture, and planted during the autumn months, would be troubled with the boll weevil. The first crop was planted in September, three years ago, the acreage being very small, and selected sea-island seed from Florida was used. No boll weevil appeared, and a good crop of cotton was obtained. After the crop was gathered every particle of rubbish from the plant was burned. The second year produced equally good results, and the third year has proved that cotton planted in Cuba in September will escape the ravages of the boll weevil, provided that care is taken that the insect is not imported into the field, and that all rubbish is burned directly after the crop is gathered. This matter is of great importance to Cuba, as there are many localities in the island where conditions generally are favourable to the extensive growing of cotton of the long staple variety.

MEETINGS FOR THE ENSUING WEEK.

TUESDAY, MAY 28...Royal Institution, Albemarle-street, W., 3 p.m. Professor W. M. Flinders Petrie, "The Formation of the Alphabet." (Lecture I.)

Quekett Microscopical Club, 20, Hanover-square, W., 8 p.m.

THURSDAY, MAY 30 ... Royal Institution, Albemarle-street, W., 3 p.m. Professor C. G. Barkla, "X Rays and Matter." (Lecture I.)

FRIDAY, MAY 31...Royal Institution, Albemarle-street, W., 9 p.m. Professor H. T. Barnes, "Icebergs and their Location in Navigation."

Engineers and Shipbuilders, North-East Coast Institution of, Newcastle-on-Tyne, 7.30 p.m. Discussion on "The Relative Possibilities of the Diesel Oil Engine, Geared Turbine and Suction Gas Engine, as compared with the Reciprocating Engine for Marine Propulsion."

Junior Institution of Engineers, 39, Victoria-street, S.W., 8 p.m. Mr. Arthur Bourne, "Standardization of Engineering Catalogues."

Physical, Imperial College of Science, South Kensington, S.W., 5 p.m. 1. Professor G. W. O. Howe, "The Calibration of Wave Meters for Radio-Telegraphy." 2. Dr. W. H. Eccles, "On the Use of Heaviside's Resistance Operators in Air-Core Transformer Theory." 3. Mr. C. R. Darling, "The Movements of Semi-oily Liquids on a Water Surface." 4. Mr. G. L. Addenbrooke, "Experiments on Surface Leakage in Alternating Electric Fields."

SATURDAY, JUNE 1...Royal Institution, Albemarle-street, W., 3 p.m. Mr. W. L. Moore, "The Development of Meteorological Science." (Lecture I.)

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,106. VOL. LX.

FRIDAY, MAY 31, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, May 16th, 1912; THE RIGHT HON. SIR EDGAR SPEYER, Bart., in the chair.

THE CHAIRMAN, in opening the meeting, said that he knew nothing of Indian railways; he had never been to India, and he had never come into contact with Indian finance. When his friend the reader of the paper asked him to take the chair, and he (Sir Edgar) pleaded ignorance, Mr. Priestley would not let him off. He had, therefore, come to the meeting for the purpose of listening and learning. The author's qualifications to speak on the subject with which he was about to deal were of the highest. He had spent thirty-three years in the Railway Department of India, for many years of that time occupying the position of Traffic Manager to the Southern Maratta Railway. In 1901 he was appointed Under-Secretary of the Railway Department to the Government of India; in 1903 he was sent to the United States to report on the railways there; in 1905 he was made Secretary of the newly-constituted Railway Board; in 1906 he was appointed General Manager of the South Indian Railway; and in 1910 he was appointed Managing Director of the South Indian Railway in London. He, therefore, possessed the highest possible qualifications for dealing with the subject on which he was about to speak.

The paper read was—

INDIAN RAILWAYS.

By NEVILLE PRIESTLEY,
Managing Director, South Indian Railway.

The subject of my paper, Indian Railways, covers such a very wide field that it would be impossible to deal completely with it in one afternoon, without at the same time exhausting your patience and greatly exceeding the time allowed me.

There is its moral side: the influence which a railway exercises on caste and religion, as a consequence of the greater freedom of movement and the intermixing of people from the various parts of the country; its influence on Indian social customs generally; its influence on the Government itself in its civil, military, and political departments.

Then there is its material or economic side: its influence on the development of cultivation and land values; its influence on trade; its influence on the rates of commodities and wages; its influence as a means of protection against famine; its influence on the general prosperity of the country, as a consequence of the increased facilities for the movement of people and products from places where they exist in plenty to places where there is deficiency.

Then there is the practical side: the character, location and standard to which railways should be constructed; and the means to be adopted for the provision of capital for their construction; and for their improvement, after being opened for traffic, to meet their increasing business.

The moral and material influences cannot operate until the railway is provided; and before railways can be built it is necessary that capital should be provided to build them with.

It seemed to me, therefore, that my paper might be more useful at this present juncture, when the funds for railway purposes grow less ever vear, if I should try to deal, as exhaustively as the time at my disposal will allow, with the practical side of my subject, and especially with that portion of it which relates to railway finance.

I propose, therefore, to give you, in as few words as I can, a history of the policy which has been followed by the Government of India in regard to the financing of railways since their inception, and to try to lay before you the difficulties which seem to stand in the way of a more rapid progress than is being made in the construction of railways in India.

The first reference to the subject of railways in India was made in 1845, when the Honourable

Hosted by Google

East India Company forwarded to the Governor-General applications from several gentlemen, who offered to promote companies for the construction of railways in India. They all asked for a guarantee of interest to be allowed on the capital, and the Court of Directors remarked that "that mode of co-operation was liable to many objections, and likely to prove very unsatisfactory," and that "railroads in India should be constructed and managed by means of private enterprise and capital." It was found, however, that no company would undertake the work without a guarantee of interest, and as the Court of Directors seemed doubtful of the feasibility of constructing and maintaining railways in the tropics, they were not disposed to enter upon an extensive scheme of railway construction, and consented to the construction of three experimental lines only, of a total length of 192 miles, namely, a line from Howrah to Raneegunge (120 miles), a line from Bombay to Kalyan (33 miles), and a line from Madras to Arkonam (39 miles).

Later, the Court of Directors began to realise that without the material appliances which facilitate and cheapen the means of communication and production there could be no rapid progress in the country, either morally or materially; and they expressed the wish that India might, without unnecessary loss of time, be given the immense advantage of a regular system of railway communication.

The question was reviewed by Lord Dalhousie in an exhaustive Minute written in 1853. He urged the importance of a speedy and wide introduction of railway communication throughout India; he pointed out the great social, political and commercial advantages of constructing railways to connect the chief cities; and he specially recommended that, in the first instance, a system of trunk lines should be formed, connecting the interior of each Presidency with its principal port, and connecting the several Presidencies with each other.

The Court of Directors accepted the general plan proposed, and by the end of 1859 eight companies had been formed for the construction of nearly 5,000 miles of railway, with a capital under guarantee of 52½ millions sterling. Those companies were the East Indian, the Great Indian Peninsula, the late Madras, the Bombay, Baroda and Central India, the Eastern Bengal, the Oudh and Rohilkund, the Sind, Punjab and Delhi (now merged in the North-Western State), and the Great Southern of India (now the South Indian, and since converted to the metre gauge) Railways, all constructed on the 5 ft. 6 in., or what is now generally known as the broad gauge. They were given a free grant of all land required for the railway and a Government guarantee of 5 per cent., Government reserving to themselves the option of acquiring the railway at the end of twenty-five years, or at intervals thereafter.

In agreeing to give a guarantee, Government anticipated that no call would be made upon them for it; but all expectations in regard to profits were destroyed by the heavy outlay on the railways, due chiefly to their being constructed to a standard far in excess of the needs of the time or the actual work which the railways were designed to perform. Conveniences were provided which, while in themselves desirable, were unnecessary for the safe or efficient operation of the railway, and some of the lines were built with a double track, the necessity for which did not arise till a generation later. The earnings which might, and doubtless would have been sufficient to cover interest charges on a reasonable expenditure, proved utterly inadequate to meet the guaranteed interest on the outlay actually incurred, and Government had to make good the deficit, which in the year 1868 had reached the large sum of 166½ lacs, or £1,496,918. A general rise in prices and wages which took place about this time, coupled with the Orissa famine of 1865–67, followed by the prolonged drought in the United Provinces and Rajputana in 1868–70, made the increasing demands on account of guaranteed interest extremely inconvenient, and the whole guarantee system fell into disrepute.

When, therefore, it was desired still further to extend the railway system, the guarantee principle was regarded as too burdensome to the country, and, as unguaranteed private enterprise still held aloof from railway projects, it was decided in 1869 that the State should build all railways in the future, and provide the capital from loans or from the surplus revenues of the country. It was at the same time decided to adopt the metre, or 3 ft. 3⅜ in., gauge for railways to be constructed by the State, as the 5 ft. 6 in. gauge, to which the railways had till then been constructed, was found to be too costly.

As a result of this change in policy, the Indus Valley and the Punjab Northern Railways (since converted to the 5 ft. 6 in. gauge and now merged in the North-Western State Railways) and the Rajputana-Malwa (now merged in the Bombay, Baroda and Central India) Railway were constructed, and later the Tirhoot (now merged in

Hosted by Google

the Bengal and North-Western Railway), the Northern Bengal (now merged in the Eastern Bengal State Railway), and several other lines of less importance which have been absorbed by the railways adjoining them.

Government, however, soon found that, in consequence of war and famine, they could not maintain the provision of funds requisite for uninterrupted construction, and they were again obliged, in 1876, to resort to guaranteed companies. The improved condition of the money market and of the country generally, enabled Government to get the capital on much easier terms, and the Bengal-Nagpur, the Assam-Bengal, the Indian Midland (now merged in the Great Indian Peninsula), and the Southern Mahratta Railways were constructed under the revised terms.

About the same time, endeavours were again made to induce unguaranteed companies to undertake construction, and four companies responded, namely, the Nilgiri, the Delhi-Umballa-Kalka, the Bengal Central, and the Bengal and North-Western. The first of these became bankrupt; the second and third eventually received a guarantee; and the Tirhoot State Railway had to be leased to the fourth to enable it to earn a sufficient dividend to satisfy its shareholders.

When the country recovered from the effects of war and famine, construction by the State was again resumed; but the amount of money which could be made available for railway purposes was small, and Government had soon to face the further difficulty arising out of a steadily falling exchange. The fall in exchange at last became so serious that Government felt obliged to curtail their gold liabilities, which necessarily increased so long as they continued constructing railways from funds provided or guaranteed by the State; and they again sought the assistance of the public. They could not offer a guarantee, but they did offer what seemed to be the next best thing, namely, money help until the company had secured its position as a dividend-earning concern.

In pursuance of this policy, rules, known as the Rebate Terms, for the construction of railways without a guarantee, were formulated and published in 1893. These rules allowed of the grant of free land; of the branch being fully equipped with rolling-stock by the main line and worked by it for not more than 50 per cent. of the branch's gross earnings; and of the payment by the main line of a rebate up to 10 per cent. of the gross earnings derived by the main line from traffic interchanged with the branch, so as to make up the dividend to 4 per cent.

The Southern Punjab, the Ahmedabad-Parantij and the South Behar Railways, 506 miles in all, were constructed under these rules, but the terms notified had to be considerably modified to secure the promotion of the companies—the South Behar Railway had eventually to be guaranteed—and it was made clear that the terms were not sufficiently attractive to the investing public.

The embarrassment caused by the shrinking rupee was put an end to in 1893 by the stoppage of the free coinage of silver, which arrested the fall in exchange. But Government did not yet feel able to launch out freely on railway expenditure. The net earnings of railways did not anything like cover liabilities in connection with railways, and while this deficit continued Government hesitated to enter upon such a programme of railway construction as the needs of the country demanded, because of the fear that any increase in gold liabilities might lead to further taxation to make good the deficit in the railway account.

By 1896 this deficit had reached nearly 259 lakhs of rupees, or over $1\frac{3}{4}$ millions sterling. An endeavour was, therefore, again made in 1896 to attract private unguaranteed capital, but as the 1893 branch line terms had produced such very small results, the total additions to the mileage of railways constructed under these terms having been only 506 miles, the rules for the construction of branch lines were revised with a view to making the terms more attractive. The new rules permitted of the grant of free land; of the branch being fully equipped with rolling-stock by the main line and worked by it for a sum which was not to exceed 50 per cent. of the branch's gross earnings; and of payment by the main line of a rebate up to the full extent of the net earnings derived by it from traffic interchanged with the branch, so as to make up a dividend of $3\frac{1}{2}$ *per cent. in rupees* on the capital as entered *in rupees*.

While, therefore, the new rules widened the benefits in one direction, they took them away in another, and it was soon made quite evident that the revised terms were even less attractive to the public than the 1893 terms. Only three railways, the Tapti Valley, the Ahmedabad-Dholka, and the Mymensingh-Jaggannathganj Railway—a total length of 245 miles—were promoted after the issue of these revised terms, but in no case were the actual terms prescribed

Hosted by Google

adhered to, and in the case of the first two lines the 1893 terms were preferred.

The Government were, therefore, once more driven back on their own resources. These, however, were now in a better condition, as the anxiety on account of the annual deficit in the railway account was passing away. In 1900 the corner was turned, and in that year, for the first time in the history of railways in India, there ceased to be a deficit. The net earnings derived from railways not only covered all liabilities, but left a surplus balance of no less a sum than Rs. 8,72,391, increased in the following year to Rs. 115,41,198. It was now believed that there would no longer be any difficulty about providing all the funds required for railway purposes in India, and, on strong representations from Lord Curzon's Government, an enlargement was made of what is known as the "Programme," and money was more freely provided by the State for capital expenditure on railways.

But a difficulty which had so far been rather brushed aside in the anxiety to provide funds for new lines of railway, now began to force itself on the attention of Government. Throughout the period of financial stringency, the major part of the money which could be made available for railways was devoted to the construction of new lines. The construction of these new lines, which were all internal lines, threw an increasing amount of business on to the old or seaboard lines, which were already finding it difficult to conduct their own very rapidly-developing business. It soon became apparent, therefore, that unless the existing railways were to fail in their purpose, funds, and large quantities of funds, must be supplied to them to enable them to provide the necessary facilities in the shape of rolling-stock, larger stations, etc., and in some instances even the doubling of lines, for the carriage of the traffic offering.

The Government seemed unwilling to raise more money to meet these increasing demands, so the only way out of the difficulty was to curtail the programme of construction of new lines and to make larger allotments of funds to existing lines. This was accordingly done, but it satisfied neither claimant for funds. The situation eventually became so acute that a Committee was appointed by the Secretary of State in 1908, under the presidency of Sir James Mackay (now Lord Inchcape) to report, among other matters, on "whether the amounts allotted in recent years for railway construction and equipment in India are sufficient for the needs of the country and for the development of its trade, and if not then what additional amounts may properly and advantageously be raised for this purpose."

The Committee reported "that the equipment of Indian railways had been unequal to the requirements of trade"; and they recommended "that the allotments for railway construction and equipment should be increased beyond those of recent years." They further expressed the opinion "that for some years to come the effective limit of the amount to be spent in any year will be the amount that can be provided," and they recommended "that the programme of annual expenditure on railway construction and development in India be for the present fixed at £12,500,000, equal to £100,000,000 in the next eight years."

In no single year since these recommendations were made has the Secretary of State found it possible to provide so large a sum of money as £12,500,000 for railways. In 1911–12 all that could be provided was £9,500,000, of which no less a sum than £6,358,000 had to be devoted to existing lines. Of the balance, new lines already begun were given £2,382,000, and the very small amount of £760,000 was allotted for the construction of further new lines. The position, apparently due to political reasons this time, is still worse for the year 1912–13. The total allotment is only £9,000,000, of which £6,341,200 is allotted to existing lines. Of the balance, £2,578,800 is to be spent on new lines the construction of which had already been begun, and the very insignificant amount of £80,000 is to be devoted to the construction of new lines, with which sum *fourteen miles of line* are to be constructed. It is, however, expected that a further sum of £203,100 will be spent on new lines, of which £43,333 is to be contributed by the Famine Insurance Fund, £3,466 by provincial governments, and £156,266 by branch lines companies. But even with this addition, the total amount to be spent during the year on new lines is only £283,100, which means that during the year about seventy or eighty miles of new railways will be begun, when 1,000 miles a year would not be too generous a programme of railway construction for India. In other words, the work of opening up the country by the construction of new lines is practically at a stand-still.

That the country needs every penny of the 12½ millions sterling which Sir James Mackay's Committee considered that it should be given, is very clearly demonstrated by the reports of

Hosted by Google

congestion on railways which come home from India by every mail, and the clamorous demands for more new lines from all parts of the country. That the Secretary of State has real difficulty in providing so large a sum from the resources at his disposal is also very clearly demonstrated by the reception given to the recent 3½ per cent. India loan of £3,000,000. The issue price was fixed as low as 93 per cent., and yet only 15 per cent. of the loan was subscribed by the public. The Secretary of State had secured the issue by having it underwritten; but it must have cost another 1 or 1½ per cent. to get this done, and the amount actually received could not have been more than 92 or 91½ per cent.

With evidence such as this before him, it is perhaps not surprising that the Secretary of State hesitates to go to the market for large sums of money; but the demand for funds for railways must be none the less met, if the progress of the country is not to be arrested; and a further attempt is being made to try to induce private unguaranteed companies to undertake the construction of new railways, by again revising (in June, 1910) the branch line terms.

It will thus be seen that the railway financial policy of the Government of India has been one constant see-saw; that their best intentions have been frustrated at one time by famine, at another time by war, at another time again by currency difficulties, at another time by political considerations, and at all times by the state of the money market; and that at the end of sixty years the position is that only 33,100 miles of railway have been constructed altogether in a country whose area is 1,773,168 square miles, whose population is over 300 millions, and the development of whose trade, indeed of the country itself, is being hampered, and badly hampered, by the want of adequate facilities. Of these 33,100 miles of railway, the State has itself had to build about 26,000 miles, either directly or through companies under its guarantee; only 1,573 miles have been constructed by companies without a Government guarantee, and only 1,139 miles by companies under the Rebate Terms. In other words, the conditions governing the provision of funds without a State guarantee have not had the effect of attracting the investing public, and Government have been obliged to find practically all the money required for railway purposes in India.

Of the remaining mileage, 3,882 miles of railway have been provided by Native States, notably Hyderabad, Mysore, Baroda, Jodhpore, Bikaner, and the Kathiawar and Punjab States; and 354 miles by or under the guarantee of District Boards, of which 199 miles were constructed in Bengal and 155 miles in the Madras Presidency.

Several of the district boards in the Madras Presidency, chiefly on the initiative and advice of Mr. (now Sir Francis) Spring, have, with very commendable enterprise, commenced to raise a fund for the construction of railways in their districts by levying a special cess of three pies in the rupee on occupied lands. Up to the end of March 1911 they had between them collected Rs. 43,30,605, or £288,707; but no railway has as yet been begun, as no one of these District Boards has so far collected enough money from its cess for the construction of the railway in which it is interested, and there have been difficulties of one kind and another in the way of its raising a loan or obtaining the money by guarantee on the security of its cess. How soon, therefore, these railways will be begun it is difficult to forecast. There seems a tendency for the Government and District Boards to require railways of high standards, and if that policy is adopted it must be many years before enough funds will have accumulated to cover the cost of the several railways.

Whether the branch line terms of 1910 will be found sufficiently attractive to investors remains to be proved. They are undoubtedly conceived in a more practical and generous spirit than were the terms of 1893 and 1896. Speaking broadly, they allow, with other concessions of less importance, of the branch being provided by Government with free land; and of its being equipped with rolling-stock by the main line and worked by it for not more than 50 per cent. of the branch's gross earnings. So far, they are the same as the rules of 1893 and 1896. The new rules, however, allow a rebate by the main line of such a sum not exceeding in any year the net earnings of the main line from traffic interchanged with the branch, as shall, together with the branch's own net earnings, make up an amount equal to interest at the rate of 5 per cent. per annum on the capital expenditure of the branch. But they specially require that the capital must be expressed in rupees, and that subscriptions must be invited only in India, and they are made applicable only to "branch lines forming feeders."

The experience of the past has not shown that capital is forthcoming in any large

quantity in India. Even Government loans do not attract more than a small portion of the money required for the service of India. The sum so far raised under the new branch line terms for expenditure in the year 1912–13, after the terms have been before the public for twenty-one months, appears to have been only £156,266, with which sum sixty or seventy miles of railway can be constructed. It is, therefore, more than doubtful whether a sufficiently large amount can be raised in India every year under these terms to increase appreciably the rate of construction and to afford any real relief to Government; and if the rule is rigidly adhered to of requiring the capital to be raised only in India, the prospects of accelerating railway construction are not bright.

Then if the terms are confined to "branch lines forming feeders," the Government will still have to find the money for lines which do not strictly fall within this category. There are numbers of such lines still to be provided all over India, especially in Central and Southern India, and if the Government are to rely upon their own resources to find the capital for these lines, the experience of the past few years does not hold out much hope of their construction in the near future.

But in any case the success of the new terms will depend upon whether there is a reasonable prospect, amounting almost to a certainty, that the income of the branch from its own earnings and from the rebate will yield a return of 5 per cent. on the company's capital from the date of opening and a higher return within a very few years after opening. That a lower return will not attract capital—in England, at all events—is very evident from the fact that good, safe investments, like the Bengal and North-Western and Southern Punjab ordinary unguaranteed stocks are quoted in London at prices which yield over 5 per cent. to the investor. That returns of 5 per cent. and more can be obtained from the day of opening, by branch lines constructed in India, has been demonstrated more than once; but whether they will be obtained depends upon three factors—namely, the outlay on the branch, the earnings of the branch and the value of the rebate.

The expression "Rebate" has not been very happily chosen, and is not understood by, or easily intelligible to, the ordinary investor. What Government really offer is a subsidy; and though they refrain from fixing a definite amount to that subsidy, and leave the amount to automatic adjustment, it is still a concession which may have a considerable value and may make just the difference between failure and success. Their offer is that if the branch line's income from its own local traffic, that is traffic which does not pass off the branch, and from its own share of the income from traffic interchanged, that is, traffic which is exchanged with the main line, is not sufficient to pay 5 per cent. on the branch's capital, then the main line shall pay to the branch such share, up to the whole of the main line's net income from the traffic exchanged with the branch, as may be required to make up the branch's income to 5 per cent. Government do not pledge themselves that the addition of this rebate will make the dividend up to 5 per cent., and the investor has to take the risk that it may not do so.

Unfortunately Government do not give any idea of what income may be expected by the branch from the main line on account of rebate. There have been numerous branches opened all over India, and the value to the main line of the traffic interchanged with these branches could have been easily ascertained, and would have proved very valuable in enabling people to estimate the amount they might expect to derive from rebate and their chances of a 5 per cent. return on their money.

The Railway Administration reports, however, show that in the case of the Southern Punjab Railway, which at the time was 400 miles long, and which received the same amount of rebate as is offered under the new terms, namely, the entire net earnings of the main line from interchanged traffic, the rebate received from the main line varied between 0·11 and 0·60 per cent. on a capital outlay of Rs. 53,651 per mile. In the case of the Tapti Valley Railway the rebate received from the main line is shown to have been between 0·25 and 0·35 per cent. on a capital outlay of Rs. 83,190 per mile; but the rebate in this case was payable only to the extent of 10 per cent. of the gross earnings, and not to the extent of the entire net earnings of the main line from interchanged traffic.

The income per cent. on the branch line's capital that will be obtained from rebate, depends, in the first place, on the amount of the rebate itself, and in the second place on the amount of the capital outlay; and the amount received as rebate will yield a high or low percentage on the capital, according as that capital has been low or high.

Assuming that the outlay on the branch is kept sufficiently low to allow of the rebate yielding a full 1 per cent. on the branch's

Hosted by Google

capital, then the branch must earn 4 per cent. from its own earnings to yield a return of 5 per cent. to the investor.

Taking all the railways which have been constructed at various times in India, not one quarter of them have earned more than Rs. 80 a mile a week during the first few years of their existence; and there are some railways yielding large returns on their capital which, after having been opened for several years, are not yet earning Rs. 80 a mile a week.

To obtain a return of 4 per cent. out of a gross income of Rs. 80 a mile a week, and a net income of Rs. 40 a mile a week, the working expenses being taken at 50 per cent. of the gross earnings, the outlay, *including preliminary expenses and interest on capital during the period of construction*, must be kept within Rs. 52,000 a mile.

It is not impossible to construct a serviceable railway in India for this amount. Many have in times past been constructed for much less. But if the cost is to be kept within the limits which the income justifies, the ideas as to the standard to which railways should be constructed, at present so widely held in India, will need to be considerably modified and the Government rules governing the construction of railways in India will need to be revised.

Those rules require bridges to be built strong enough to carry on the 5 ft. 6 in. gauge an axle-load of 22½ tons, and on the metre gauge an axle-load of 12½ tons. Girders strong enough to carry these weights may be necessary to-day in the case of the great trunk lines of Northern India; but in the case of many railways in India they will not be necessary during the life of the girders; and in many others they will never be necessary at all at any time. In the case of the South Indian Railway, after the 5 ft. 6 in. gauge section has been open for over fifty years and the metre gauge section for over thirty-five years, the heaviest axle-load is only 16 tons on the 5 ft. 6 in. gauge, and 9 tons on the metre gauge, and we have been advised that it would not be easy to design an engine for the metre gauge with a 12½ ton axle-load. Nevertheless, all new bridges on our system, and all bridges on projected lines off our system are required to be designed strong enough to carry the weights prescribed. Then the rules require all platforms to be built 600 ft. long and 18 ft. wide, even though it may not be intended to book any passengers to or from the station, as at stations which are opened only for the purpose of crossing trains. The length of sidings or loop lines at stations is prescribed as 1,800 ft., when half that length would in most cases be sufficient, at the beginning at all events. Banks and cuttings have to be of a standard inconsistent with economical construction, ballast of a full section is required, and a weight of rail is demanded sufficiently heavy to permit of the highest speeds from the date of opening.

These rules are not the product of to-day or yesterday. They are the growth of years, and, beginning at a period antecedent to the formation of the Railway Board, they have from time to time been revised in the direction of greater stiffening, until they are to-day as stated above.

Though the actual rules were issued subsequent to the construction of the Tapti Valley Railway, the result of the policy which they enforce may be seen in the Tapti Valley Railway. It cost Rs. 83,190 a mile for its 155 miles, when the country could have been opened up for a considerably lower outlay. In the first year after it was opened to traffic its gross earnings were Rs. 74 a mile a week; its net earnings and the rebate together represented 2·90 per cent. on the capital outlay; and it was five years before it began to earn more than 4 per cent. on its capital. The consequence was that the shareholders were bitterly disappointed; the branch line terms were seriously discredited; and when the promoters of the Tapti Valley Railway tried later to promote the Ahmedabad-Dholka line, they were unable to get the public to subscribe all the capital required; and, to save the project from failure, Government had to lower the standard of construction and had themselves to take up the shares which the public had refused to subscribe.

The question of revising the bridge rules and the book of standard dimensions is now under the consideration of the Railway Board; and it remains to be seen whether they will be so revised as to permit of the construction of railways to such a standard and at such a cost as will afford a reasonable prospect of the income which it is estimated the line will earn, yielding, with the assistance of the rebate, the return of 5 per cent. of which hopes are held out by the branch line terms.

In every case where the capital cost of a line has been kept low, as in the case of the Ahmedabad-Dholka and the Ahmedabad-Parantij metre-gauge lines and the Amritsar Patti 5 ft. 6 in. gauge line, the railway has, from the commencement, fulfilled and handsomely fulfilled, the expectations of investors. Where consideration

has not been given to the amount of capital outlay, as in the case of the Tapti Valley Railway, the project from the point of view of the original investor was a complete failure. Even the Southern Punjab Railway, splendid property as it is to-day, and cheaply as it was built, was constructed too expensively for the anticipated income, with the result that for several years after the line was opened the shareholders did not receive an adequate return on, and were greatly dissatisfied with, their investment.

The branch line terms have, presumably, been notified with the serious desire to attract unguaranteed capital, not in small amounts but in such large amounts as will relieve Government of the necessity of finding funds for new lines; and if they are not to fail in their purpose, it must obviously be the particular care of Government to see that the outlay on any line projected under the terms is kept within such limits as will afford a reasonable prospect of the earnings yielding the return of which the terms hold out hopes. No one is more interested than Government are that the terms should prove successful; and if, for reasons of policy, uniformity of gauge is necessary, or a higher standard is required in the case of any particular line than the income expected from the line would justify when the project is considered from the investors' point of view, then an unguaranteed company should not be allowed to undertake the line and it should be constructed by the State.

It is, however, a question for serious consideration whether even the State itself is justified in spending the large sums which high standards necessitate when the country could be sufficiently well served by less expensive lines; and in imposing charges on the general revenues of the country in consequence of the failure of the railway to earn sufficient to cover interest charges on its high outlay, at a time when the programme of new construction is being seriously restricted and the country needs all the money it can get for educational and other purposes.

The country in many parts is devoid even of metalled roads, and what it wants is means of easy communication, not high-grade railways over which trains can be run at express speeds; and a business man, whose property needed opening up and developing as badly as India does, would strive for quantity and leave quality to follow later, when business had developed sufficiently to justify quality as well.

That, at any rate, is the view which the Jodhpore and Bikaner Durbars have taken of the matter. They have built light, cheap, metre-gauge lines, which have cost them, fully equipped with rolling-stock, only Rs. 25,606 a mile for the 831 miles of which their system consists; and these lines have served their territories perfectly efficiently for the past thirty years.

Compare this with the Nagda-Muttra Railway, which has just been constructed by the State, and has cost Rs. 118,000 a mile for its 339 miles, not reckoning interest on capital during construction, which amounted to about another Rs. 12,000 a mile. Local circumstances may make it impossible always to construct as cheaply as the Jodhpore and Bikaner States have constructed their railways; but there is a very wide margin between Rs. 25,606 and Rs. 118,000. The country traversed by the Nagda-Muttra Railway could have been sufficiently well served in the first instance by a light broad-gauge line for half, and by a light metre-gauge line for much less than half of the sum actually spent on the Nagda-Muttra line and two miles or more of railway might have been given to the country for every one that has been provided; and this, notwithstanding the fact that Government have been so badly pressed for funds that they are reduced in the present year to a construction programme of *only fourteen miles* from funds provided by themselves, and to another sixty or seventy miles from funds provided by outside agencies.

There are thousands of square miles of country in India whose progress, both material and moral, is being retarded for want of railway communications. Every district now short of railways can support a railway of some kind; but few of them can straightaway support a railway built up to modern ideas of standard.

Is it, then, wise statesmanship, in the circumstances, to pour money into lines of the standard of the Nagda-Muttra—it is not the only one of its kind under construction at the present moment—and open up only a few miles of territory each year? Or is it truer statesmanship to emulate the policy of the Jodhpore and Bikaner Durbars and open up numerous miles of territory each year with light cheap lines? Those are the really important questions for Government to consider, and on the decision which is arrived at will depend the success or failure of the new branch line terms.

If no regard is paid to the amount of the capital outlay on new lines, and if companies are not only permitted but compelled to construct to a standard entirely out of harmony

Hosted by Google

with the income expected, the new terms cannot prove any more successful than the old. But if the capital outlay is made to come down to such a figure as will ensure a reasonable prospect of the anticipated income yielding 5 per cent. at once with the assistance of the rebate, and more than 5 per cent. within a very few years after opening without the assistance of the rebate, my belief is that the new branch line terms will achieve the object which their framers had in view, provided, of course, that they are modified in the directions already indicated, and in a few other directions of not great importance from the point of view of Government; and that they will be the means of procuring, without a State guarantee, all the capital required for the construction of new lines in India, and of procuring it in ungrudging amounts. If other countries, and even South American republics, can get all the money which they want for railways without a State guarantee, there is no reason why India, with her credit as high as it is, should not be able to get all the money she wants also, if she too will treat a business proposition in a businesslike way.

DISCUSSION.

The Chairman (Sir Edgar Speyer), in opening the discussion, said he was sure he was expressing the wishes of the meeting in offering to the author their heartiest thanks and congratulations on the most able and interesting paper he had read. As he had stated in opening the meeting, he was entirely ignorant on the subject of Indian railways, and he hoped any remarks he ventured to make after listening to the paper would be taken as the expression of a business man not conversant with Indian problems, but one who looked upon the question broadly, because all business had certain underlying principles, whether it was carried on in India, Canada, or any other country in the world. The fact that had struck him most in the able survey the author had given was that the railway provision in India must be insufficient. The statement had been made in the paper that there were 33,000 miles of railways in India, a country with an area of 1,773,000 square miles, and a population of 300 millions. Figures were only significant by way of comparison, and there were two other sets of figures which came to his mind to which he would like to direct attention. Canada had about the same number of miles of railway as India, 32,000, or would have in a year, when some of the trans-continental lines were finished; and Great Britain had about 30,000 miles of railways, so that the three countries of India, Canada and Great Britain had about the same length of railway lines. But India had a population of 300 millions, Canada eight millions, and Great Britain 45 millions, and the author had therefore made out a good case, even to those who knew nothing about India, that that country was not sufficiently provided with railways. It seemed to him a most extraordinary thing that the educated and wealthy population of India should not be sufficiently interested in providing more railways than existed to-day, and that they should not appreciate the civilising mission and the fructifying factors which all the railways in the world had been shown to possess. No doubt there were good reasons for such a state of affairs, but the problem seemed to him to be one not only for India, but for the Empire at large. The people of this country wanted India to be developed, in order that she might produce foodstuffs and other things which the world required very badly. As he listened to the author he could not say that he felt like blaming the Indian Government for the lack of railway communication which existed; he rather felt sympathy with them, because the history the author had unfolded clearly showed that the Government were in a very difficult position. So far as finance was concerned, a subject on which hs was supposed to know a little, it seemed to him that the Indian Government had been very much handicapped. Those present no doubt appreciated that, before the Trustee Act came into operation, Indian Government Stock shared with Consols the great privilege and distinction of being practically alone available for the investment of trust money. On the passing of the Trustee Act that was changed, and the Indian Government was now placed in competition with all the Colonies. He did not think that was a bad thing; on the contrary, no doubt it was a right thing to do; but the old happy days in that respect were over for India, and when it required money they knew that other people wanted money too, and that the credit of Indian stocks could not be the same as it used to be. That action must have had its effect on railway construction, because whilst formerly trust funds were available only for Indian stocks and Consols, at the present moment a great deal of trust money did not go to India. The Indian Government, therefore, had to be very careful in its policy about railway construction and other expenditure. Another point about Indian credit generally was the fact that all over the world at the present time the public wanted a better return for its money, as a consequence of which very high-class investments were not so much sought after at the present moment as they were ten years ago. That was partly due to higher expenses of living, which was again due to greater gold production in a large measure, and also to the extravagance of most people who required a better return for their money. All those points affected the question. Another point to be borne in mind was that, anywhere in the world where railways depended on Governments, development was slow. He did not say that for the sake of making the criticism that Governments were slower than individuals. They were bound to be. After all, in every Government, if it were examined,

Hosted by Google

it would be found there was also some red tape sticking out of some coat pocket. He did not wish it to be understood that he was an opponent of State railways. That was by no means the case. He thought that question entirely depended on the country; it was impossible to generalise. On the whole, he believed the future would be with Government railways. He thought they would more and more drift into State railways all over the world; but he thought the author had made out a case that in India the State railways had not sufficiently developed the country—at any rate not fast enough. The great question, it seemed to him, which the paper asked was, why had private capital not been attracted to India? No doubt it was partly due to political reasons. Capital was timid, and the stories of unrest in India had no doubt frightened capital to a great extent. It was to be hoped that after the King's visit, which had been such a great success, that unrest would be on the wane, and from all he heard there was great hope that that would be the case. If that was so, he hoped capital would be more attracted towards railway construction in India. But what he could not understand, and what he hoped subsequent speakers who knew India would explain, was how it was that Indian native money, of which a great deal existed, was not forthcoming. There must be some reason for that state of affairs. He could not judge whether, if a different policy had been pursued by the Government, better results would have been obtained, and the case called for careful inquiry. He confessed that, after listening to the rules which the author had explained, he would not personally attempt to build railways in India. Life was too short to work under such complicated rules, but possibly many clever people were satisfied with them. His experience had never led him to the East, but he knew that in Canada the Government had a very practical way of encouraging railway construction. He had been interested in one railway there himself. The Government generally in those great railways guaranteed a first mortgage of a limited extent, and showed its faith in the future of the line. Private enterprise then came along and took a second charge, and that system had proved eminently successful in Canada. He did not know whether it would be applicable to India, but he threw it out as a means by which money had been raised in other Colonies. One point which the author made seemed to him to be eminently sound, namely, that railways in their initial stages were built too substantially. Heavy charges on a young enterprise due to that fact seemed to him to be unsound. In the United States of America, where railway construction had proceeded in a very remarkable way in the last fifty years, the railways were generally built by private enterprise. The rule, generally, had been to build railways lightly, to trust to the development of the country, and to use the surplus for strengthening the railways afterwards. Had that not been done, he was sure the railway mileage of the United States would not be what it was at the present time, and he thought the author had made out a strong case from the point of view that Indian railway policy was open to question. A great desideratum, as the author had emphasised, was how to attract money to India, and it should not be beyond the wit of man—certainly not beyond the wit of business men—to solve that question. After all, conditions changed, and it was sometimes necessary to have a change in policy. He wondered whether something like the following policy would attract capital, namely, that one of the successful lines in India should be taken over by a private company, at a fair valuation, and be run as a private concern. That, he thought, would have several advantages. First of all, he was a believer in private enterprise, because he believed, without wishing to give any offence, it was more elastic and more efficient than a Government could ever hope to be. If people put their money into a concern, they did their very best to get a good return for their money, but Governments were not exactly in the same position. If the results of such a railway being taken over by a private company were very good, and the surpluses were used to build branches, and good dividends were earned, that would perhaps encourage capital to come along and build railways which were so sadly needed in India. It might be the means of stimulating railway construction in India, and be a great encouragement to investors. That might be a counsel of perfection. Everyone present appreciated the great importance of the subject, and, after having listened to the paper, he confessed he felt tempted to give the matter more attention than he had done in the past.

Sir Bradford Leslie, K.C.I.E. (Chairman, Southern Punjab Railway), said the Government terms for branch lines were framed with the view of inducing zemindars, district road boards, and others locally interested to form Indian companies to undertake their construction. The rebate system was defective because, firstly, however cheaply constructed, for several years after opening the local receipts of a branch line might be absorbed by working expenses; and, secondly, initial rebate on the traffic of an undeveloped district might be insufficient to supplement any net receipts to the extent required to make up the total receipts to 5 per cent. The first difficulty was generally got over by the parent line undertaking to provide rolling-stock, and work and maintain the branch at 50 per cent. of its gross receipts. That gave the parent line the right to dictate the standard to which the branch was to be constructed. The parent line took care to protect itself by requiring the highest standard it could, viz., the State railway standard, with the result that on that basis the estimated cost was often prohibitive. It would be better policy to permit construction to be of the cheapest type, by which through communication could be effected sufficiently for initial traffic. Alignment, curves, grading, ballast, permanent-way, bridges, stations,

etc., could all be gradually improved. Capital for improvements reasonably necessary, as traffic increased, should be debited to the branch line, excepting minor works which were usually charged against revenue. In many cases it would be an advantage to permit second-hand material, removed from the parent line, to be used for the construction of branches. That would enable the trunk lines to realise a good price for material no longer fit for main line traffic, and thereby lighten the cost of renewals. He trembled in making such a suggestion for fear of incurring the censure of the orthodox. The second difficulty, namely, that in undeveloped districts local earnings plus rebate might be insufficient to amount to 5 per cent., even on a cheaply constructed line, could only be surmounted by the trunk-line system or State agency, either of which could afford to make extensions into unsettled districts, trusting to future developments. In cases where the great trunk-line systems made, maintained, and worked their own branches in their own territory, they should be absolutely unfettered by grandmotherly legislation as to standards of construction. The only danger was that branch-line construction might be used to relieve the cost of main-line working—a possibility that could hardly be imagined in these days of expert managing directors. Indian railway companies were administered and managed by accomplished staffs, second to none in the world. Assuredly Government might trust those men to make branch lines that would answer the purpose, namely, to afford railway communication to outlying districts, with due regard to efficiency for initial traffic. Surveys and estimates must, of course, be subject to Government approval, but men with local experience were the best judges of the scale on which the railway should be constructed. To enable new lines to earn 5 per cent., not only must capital outlay be kept down, but traffic had to be carried at very low rates to compete with ekkas, bullock carts, camels and donkeys. Government inspections to see that the sanctioned standard was complied with were necessary and were always welcomed by railway officers, but it should be left to the local administration, on the recommendation of their departmental officers, to fix the type that would afford communication in the cheapest way they could, with the resources at their command. Unless that principle was accepted, railway extension, of all things the most important for the welfare of India, could never progress as it should. The cost of construction was 30 per cent. higher than it was twenty years ago; and prices were still rising. The longer railway construction was deferred the more it would cost and the less it would pay.

Mr. L. R. W. Forrest said he was sure those who had listened to the paper hoped the author would on future occasions treat of the other sides of the Indian railway question, and describe the influences the railways were having on the social, religious, political and economic conditions of India. The author had very properly commenced with the finance, without which there would be no railways to discuss, and had given a clear description of how the capital was raised, and for which lines it was raised from the very commencement. He had referred to the recommendations of the Committee of 1908 for the raising of £12,500,000 a year, which had not been found possible. With all due deference to the India Office, he (the speaker) thought it would be possible if the authorities would be more liberal in their terms. With Canada, Brazil, Russia, and other countries offering 4 to 4½ per cent. for railway debentures and guaranteed bonds, it was simply delaying the development of India to refuse to allow the various main lines to issue debentures except at impossible rates, in the present condition of the demand for English capital from all parts of the world. The Indian railways could afford to pay 4 per cent., and if that rate was offered as much capital as was wanted could be raised, probably at a slight premium. One quarter per cent. made all the difference in attracting investors, and that meant some £7,500 a year for interest on three millions, a trifling figure compared to the benefit gained by that extra expenditure. He asked those present to consider the loss caused to the railways, to the cultivators, to merchants and mine-owners during the present year by the want of waggons and the want of a second line of rails on some of the lines. He alluded especially to the G.I.P. Railway, which was refusing traffic from three of the adjoining main lines, partly for want of rolling-stock and partly from having only a single line of rails between Nagpur and Bhusawal. The shortage of waggons on the East Indian Railway had caused the consumer to pay for his coal an excess in price which would cover the extra interest many times over. The author had given an interesting account of the hitherto half-hearted attempts of the Government to attract rupee capital, and had properly commended the last endeavour made in the form of concessions, by which a rebate was given towards a return of 5 per cent., with division of profits over 5 per cent. Those terms appealed to the native public. They liked the slightly speculative character of that not quite gilt-edged security, and a kind of capital was attracted which would never go into 3½ per cent. rupee paper. Owing to good trade and high prices for produce the wealth of India had increased enormously since 1905. Having been connected with feeder lines since the commencement, and his own firm having already raised three crores, he could speak with a certain amount of authority, and he could distinctly say that any amount of capital would be available on those terms if the schemes were forthcoming. But would they be? The general concession was good enough, but disputes on petty details, whether the rebate was payable on the capital issued or on the cost of construction, the amount of remuneration for office expenses and of management before division of profits, and the delay in sanctioning

Hosted by Google

projects, all deferred the formation of companies. But the chief obstacle was the unwillingness of the main lines to assist. With perhaps a single exception, there was now no attempt on the part of their managers, or even of State line managers, to develop those feeders through other companies. No suggestions were even made or invited. One reason was, no doubt, that as those main lines had, in the interests of India, been remodelled on a 4 per cent. basis, they naturally objected to assisting another company to earn a possible 5 per cent. He was strongly of opinion that Government should give any rebate necessary out of their three-quarters to fifteen-sixteenths share in the earnings of the main line, and not ask the London company to join. It was the Government of India that benefited politically by those extensions with rupee capital, and in their revenue by the increased value of land. Such an arrangement would make it much easier for promoters of feeder lines to come to terms, and projects would be more amicably arranged between the Railway Board and the other two parties. He trusted that suggestions from one absolutely *au fait* with the question of feeder lines would receive attention from the authorities. The members of the Railway Board were decidedly anxious to promote the extension of those rupee railways. He thought the Government should not tie themselves down so rigidly to certain declarations. Different proposals required different treatment. There were many lines which might be made, especially some in the neglected Province of Eastern Bengal, if there was more elasticity in Government's rules for concessions. He did not think there was a very large scope for feeders on the present expensive scale, but there was a huge field open for light railways, such as Mr. Priestley had recommended, and which was so admirably commenced by Mr. Home in the Jodhpore Railway. With reference to the author's remarks about the Tapti Valley, he was glad to say that it was now earning 5 per cent. It was the only one of the first four new feeder lines that had ever taken any rebate, and the following figures showing the increase of passengers and traffic might be interesting. The Tapti Valley Railway carried 420,936 passengers in 1901 compared with 1,184,621 in 1911, while the goods traffic increased in the same period from 104,073 tons to 228,675 tons. The Parantij Railway carried 332,385 passengers in 1903 and 772,776 in 1911, the goods traffic increasing in the same period from 52,540 tons to 92,400 tons; while the Dholka Railway passenger traffic increased from 282,038 in 1904 to 527,489 in 1911. Those figures showed that, although the traffic on a line when it was first constructed did not give much encouragement, after a few years the traffic receipts would probably be very much greater than were anticipated.

Sir J. D. Rees, K.C.I.E., M.P., pointed out that the author, in the excellent paper he had written for the purpose of informing the British public of some of the main facts relating to Indian railways, had not mentioned one way in which branch lines might be made and railway construction improved in India, namely, by getting the India Office to place the matter as far as possible in the hands of the gentleman who had given the underground railways to London. It was through the interest of gentlemen like the Chairman that the question would march forward, because it would never progress by simply following along straight official lines. It was necessary to get the subject brought as far as possible into the City of London. The great railway men of London should be tempted to interest themselves in the matter, and then possibly the intrinsic merits of Indian railways would have a far better chance of being acknowledged than if they continued to be worked on the lines hitherto adopted. There were enormous advantages in India with regard to railways which were not possessed in this country. In the first place, there was no Parliament, and there was none of that ill-informed persecution which pursued railway enterprise and was killing it in this country. Every project for extension or for improving railway communications was met in England with the most unintelligent opposition. If British capital was to go into India there must be less talk about Colonial self-government for India, because he did not think British capital would be in a hurry to seek an investment in India unless the Government was maintained on something like its present lines as a British-controlled Government. One of the reasons why rupee capital had not been coming forward was that the people who possessed it had no confidence in the people who talked in India, and who appeared to have more influence with the authorities than those solid men who would be in a position to invest capital in railways and other enterprises of that sort. An effort had been made by another school of thought to represent railways as competing with irrigation. That was an absolutely absurd contention. Irrigation schemes could only be carried on with justice to the general taxpayer when they offered a fair return, whereas a railway after a short time paid by itself, and he believed he was right in saying there was about half a million surplus at present on the railway account in India. So that the problems of irrigation and railways were not in opposition, but they should work together, and the more railways were made the far better chance there was of more irrigation schemes being carried out. The Chairman had referred to the question of the private management of railways. The Government of India showed a very practical belief in the superiority of private management by placing in the hands of private companies for management railways which practically belonged to the State; and if any further proof were needed that that was a wise system, it was only necessary to bear in mind the state of affairs which existed on the Western Railway in France, which, under State management, was conspicuous for bad management, accidents, bad returns, and generally for the evil contrast it

Hosted by Google

afforded with the lines which were under private management. He desired to emphasise Mr. Priestley's point as to the absolute necessity of keeping the cost of the construction of railways down. He thought everyone who knew Indian railways, with the expensive cut-stone stations scattered about all over the country, considered them an absurd waste of money. A shanty very similar to what was called a "halt" on the lines in this country would do perfectly well. Even on the line with which the author was connected, he must have blushed over and over again to see the palaces which were reared up for stations alongside the mud huts on the sun-baked fields. The only purpose they served was to increase the cost of construction, and he hoped that matter would receive the attention of the authorities. He was not surprised at the fact that capital was not forthcoming for the construction of railways in India in any large quantity. If once it got into the mind of the people in England who supplied capital that there was going to be some fundamental change in the Government of India, some federal system giving great control to local bodies, and that they were not to be completely controlled financially by British officers, he did not think that influx of capital would be forthcoming which was required in order to provide India with anything like a sufficiency of railways. It was all very well to say that other countries could get the money without a State guarantee, but anybody who knew anything about the South American Republics, for instance, knew that directly they had any labour difficulties they immediately introduced martial law and put an end to them. That might not be a practicable system in this country, but it was very comforting to investors. There seemed to be a wave of feeling right through the British Empire that complete changes were to be introduced in the direction of more democratic management. All he could say in answer was that people with money had no confidence in democratic management. They believed in the management of financial concerns by solid people who understood financial business. He hoped it was reserved to the author to interest British capital in Indian railways, and the fact that Sir Edgar Speyer was in the chair seemed to him to be a very happy augury.

Sir Arundel T. Arundel, K.C.S.I., thought there were only two ways in which it was possible to escape from the dilemma in which they found themselves with regard to the difficult question of capital for railway construction in India. The Secretary of State said he could not find the capital that was necessary at the interest which he was prepared to offer. In the first place there was the question of the raising of capital in rupees in India. It was well known that certain small railways had been successfully built, and were paying more than 5 per cent., which had been financed in that way. But the construction of these railways depended to a large extent upon the action of the district boards, which required education and guidance by the district officers. It was necessary to pierce the barrier of the embargo set up by the Government rules that railways must be built of a very high grade from the beginning. He hoped that when the question of Indian railways was raised in the House of Commons, Sir John Rees would urge the necessity of reducing the standard upon which the Government of India insisted at the outset. The same principle might possibly be adopted in the initial construction of railways in India as had been adopted in the United States and in Canada.

Sir James Wilson, K.C.S.I., said he was not a railway expert, nor a financial expert, nor a director of a railway, but he was very much interested in the welfare of the people of India, and he desired to look at the question from their point of view. The author had naturally confined himself to the financial aspect of the question, but the very great indirect advantages that would accrue to the people of India and others concerned from the construction of railways must also not be forgotten. When a railway was constructed in a country where previously there was no good communication it tended to raise the value of the produce and to steady prices. It gave more employment to the people, and above all it saved them from the risks of famine. There would have been a much larger mortality in India during the recent droughts had it not been for the railways. The construction of railways was also a very great advantage to traders. It gave them more trade, not only in the locality itself, but on the seaboards through which the produce passed. It was an advantage even to this country, because it obtained a large amount of produce from India. All those indirect advantages should be taken into account, and even if the Government of India could not show that they had a financial profit on railway construction, it would still be advisable to extend the railways at a small financial loss. But was there any financial loss? It had been stated that the capital outlay on lines opened in India up to the end of 1910 was 293 millions, the net earnings on which were sixteen millions, which gave a return on the capital expenditure of 5½ per cent. The figures for this year were still more satisfactory. He found that the total debt of India a year ago was 275 millions, of which almost the whole had been spent upon railway and canal construction, upon what were called productive public works, which were expected to do more than pay the interest on their capital expenditure. In 1910–11 the net gain to the State from railways alone was put down at £2,866,000, after paying, not only the cost of management and working expenses, but the interest on the capital cost of the railways, and that sum of money went to reduce the burden of taxation. The author had shown that the Government of India had been struggling for a generation to get private investors to put their money into Indian railways without giving them

a direct guarantee. In the early days of railway construction the Government guaranteed 5 per cent., and any amount of money was available on those terms. It was only since the guarantee had been stopped that private investors had been chary of investing their money in Indian railways. If the money could not be obtained in any other way, he thought it would be to the advantage of the people of India to offer a guarantee of 4 per cent. at the present time, and plenty of money would then be forthcoming for the development of Indian railways. But why should the Government give a guarantee at all? There were any number of schemes in India of railway construction which, if carried out by the Government on the principles recommended by the author, would be certain in a few years to pay 5 per cent. profit after paying their working expenses, and why should not the Indian taxpayer have the benefit of such a good investment? If he could borrow at 3¾ per cent. and invest his money at 5 per cent., the more money he could borrow and invest on those terms the better for the people of India, and the more the net profit would be which went to reduce the burden of taxation. He thought the difficulty that had been mentioned in connection with the raising of money for investment in India had been very much exaggerated. At all events, the Government of India could borrow money on most excellent terms compared with other countries. No doubt it had to pay more interest now than it did fifteen or twenty years ago, but just as Consols had gone down so had Indian Government securities. The Secretary of State for India recently raised £3,000,000 in London at 93 on 3½ per cent. Indian stock, which meant he would have to pay £3¾ interest on every £100 he actually received. The Government could also borrow money in the Calcutta market in rupees at 3¾ per cent. If a man bought Consols at the present time at 78 he obtained about 3¼ per cent. on his capital expenditure, compared with the 3¾ which the Indian Government had to pay. The City of London had to pay 3½ per cent., Liverpool, 3½ per cent., France, 3½ per cent., Germany, 3¾ per cent., Canada, 3⅝ per cent., Victoria, 3⅝ per cent., Japan, 4⅝ per cent., Argentina, 4½ per cent., China, 5 per cent., Chili, 5 per cent., Italy, 4 per cent., Hungary, 4⅜ per cent., and Russia, 4⅜ per cent. Why should India, therefore, not be content to borrow 20 millions at 3¾ per cent., invest it in railways at 5 per cent., and make a very large net income for the Indian people? Personally he would be inclined to go much further than the author, and to suggest that the Secretary of State should declare that whatever be the state of the Indian finances, whether there be a surplus or deficit, a famine or a frontier war, so long as he could borrow money at less than 4 per cent., and could invest it in Indian railways which within ten years were likely to pay 5 per cent. on the capital charges, he would borrow in the next five years £20,000,000 a year, and spend it on Indian railways.

Mr. Priestley, in reply, said that he had no remarks to make, as practically every speaker seemed to agree with the propositions he had put forward.

Sir William Lee-Warner, G.C.S.I., in proposing a vote of thanks to the reader of the paper, and in acknowledging the obligations of the meeting to the Right Honourable the Chairman, observed that the chorus of approval with which the paper and the speech of Sir Edgar had been met rendered further remarks almost superfluous. He cordially agreed that the paper was a most valuable addition to the excellent series of the closing session, and he felt confident that he should strike no note of discord if he referred to a few considerations which had escaped notice. In so far as Mr. Priestley had argued that the expenditure devoted to railways might have gone further if restrictions had been withdrawn, and a more economical outlay on stations and construction permitted, he had no objection to raise. The suggestions deserved the careful consideration of the authorities, and were sure to receive it. Technical matters were, however, beyond the speaker's capacity, and he would not criticise details. But when the lecturer complained of a see-saw policy and of undue timidity in extending railways, and when Mr. Forrest and Sir James Wilson caught up the cry and advocated an extensive and almost reckless provision of funds, it was necessary to dwell on the solid reasons for a slow and well-considered advance. Some of these reasons affected the financial situation, to which the Chairman had referred when he mentioned the influence of extended trustee securities on the price of Indian Government securities. Other considerations suggested themselves to the speaker. Railways were not the only form of enterprise for which loans were needed. Irrigation schemes, port extensions, municipal works, and other undertakings, involved applications to the market and added to India's indebtedness. Then as regards the provision of funds from the year's revenues, the claims of education, sanitation, and other spending departments must be considered. Government could not afford a lavish expenditure or increased borrowing for one purpose, however good in itself, which might throw India's finances into difficulties or unduly increase the annual charges for interest which Indian exports must pay. Another set of reasons for caution affected railways in particular, and rendered the reference to Argentina, Canada, and other countries misleading. In the first place, Indian droughts paralysed railway traffic as no other visitations of Providence did in the countries named. Secondly, floods on the great rivers of India, especially on the Tapti and Nerbudda, to which reference had been made, constantly broke down bridges, flooded whole districts, and involved risks and expenses of an unusual kind. Thirdly, the trade of India was uneven and irregular. One year a crop of wheat and seeds that no railway

Hosted by Google

could carry away before it got mildewed or otherwise spoilt by the rain, and another year no surplus of that product to be spared for export. This abnormal fitfulness of Indian trade was naturally objectionable to investors and traders, and it was a serious difficulty and cause of loss to railways. Again, population shifted. The new canal colonies were a striking example of deserts changed into populous districts, while in some parts the Indus, in its shifting course, swept away cities. Finally, there were political causes that affected India's borrowing powers as well as its income and expenditure. Sir John Rees had mentioned one, and, if the speaker might mention another, he would select the danger of a policy of protection. For any paltering with free trade which contracted the foreign market for Indian raw produce would ruin India's trade, decrease her railway takings, and injure her ability to pay interest on the capital already borrowed by her. All these considerations pointed to cautious, well considered advance in railway extension. A plunging policy would give India railways which she could never maintain. The Chairman had done a service to the Society in presiding, and his interest in art as well as his experience in business made his presence most appropriate. They all hoped to see him in the chair again, and Mr. Priestley had gratified but not satisfied the audience's appetite. They sincerely hoped that he, too, would follow up the large subject so well introduced by him, at a later date.

Sir M. M. Bhownaggree, K.C.I.E., seconded the motion, which was carried unanimously, and the meeting terminated.

Mr. J. Forrest Brunton writes: Of the paper itself, interesting and instructive as it is, I have little criticism to offer. It is largely historical, and where it is not so I agree generally with the author's conclusions, except that I am not so optimistic as he appears to be as to the success of the third and last rebate terms offered by the Government of India. While, however, there is little to criticise in the paper itself, there is much to criticise in the conduct of the Indian Government in regard to the so-called "encouragement of private enterprise" for railway extension in India—presuming, of course, that the Government of India really wished to encourage private enterprise, and this is to my mind a large presumption. I can conceive nothing more puerile than the rebate terms offered in 1893, 1896, and I fear than those of 1910 also. When the Government of India published the first rebate terms in 1893, I had the temerity to criticise them and to prophesy that they would fail to attain the object aimed at. In a letter published in the *Engineer* of December 29th, 1893, after pointing out, in the case of a particular railway then much advocated, and for which estimates of cost of construction and probable traffic had been prepared, that the additional encouragement of the 10 per cent. rebate amounted to one-fifth per cent. per annum on the estimated capital cost, I remarked: "Do the Government of India really imagine that this is adequate encouragement for the investment of private capital in India? If so they have a most extraordinary idea of encouragement, and I am afraid that capitalists will hardly appreciate their generosity." In a letter published in the *Journal* of this Society on June 28th, 1895, in which I offered some remarks on Mr. Parry's paper, "The Coming Railways of India," I again referred to these rebate terms and condemned them as valueless. I pointed out that they were radically wrong in principle. A sliding guarantee or subsidy of this kind, to be of any practical use, should increase in value in direct ratio to the need of the guaranteed. This rebate does exactly the reverse of this. If the branch line were carrying a large and profitable traffic the rebate, if required, might be of considerable value, but in such a case it would probably not be required. Whereas, if the branch line traffic were small and of little value the rebate would also be of little value, and the branch line would receive practically no assistance whatever. The Indian Government must surely have been aware of this. That those to whom the Government appealed were aware of it the result only too clearly shows. I have three reasons for fearing that the new rebate terms will be no more successful than those of 1893 and 1896. They are—(1) That while the permissible rate of interest is raised from 4 to 5 per cent., and the permissible rebate from 10 per cent. of the *gross* earnings of the main line from traffic interchanged between it and the branch line, to a sum not exceeding the *net* earnings from the same traffic, there is, so far as I know, no definite proportion fixed between the gross and net earnings. The result will be, I fear, that in branch lines where the traffic is poor, that is, where the rebate will be most wanted, the net earnings will be much less than is probably anticipated. The main line, that is, the line responsible for working the traffic, has no direct interest in keeping the working expenses low, and the net earnings decrease as the working expenses increase. (2) The position of these branch-line companies seems to me in many ways to be very unsatisfactory. They provide the capital, but they do little else. The lines are worked by the main line, and the branch line has little control. The directors and shareholders of branch lines can find little scope for business capacity or energy. They cannot hope to extend their line and to become in time the owners of an important, well-paying, self-contained railway system. They are branches to begin with and to end with, because as soon as they cease to be branches they will be absorbed into the main line, and, becoming an integral part of it, lose their separate identity. This may to some extent be sentiment, but I believe it has a not unimportant influence in preventing business men taking a more active interest in Indian railway finance. (3) What is the object of these rebate terms? Obviously it is to give a reasonable guarantee to

investors in branch lines that they will get their 5 per cent. Now Government can themselves raise money at less than 5 per cent. It is true, as the author points out, that they recently failed to raise £3,000,000 at 3½ per cent., but they got it underwritten at rates that probably work out to about 3·85 per cent. It may safely be assumed that they could easily have got the money at 4 per cent., certainly at 4½ per cent. Now why should Government offer 5 per cent. on rebate terms to branch-line investors, when they can raise the money themselves at a lower rate of interest, and pay the interest in the same way as they expect the branch lines to pay 5 per cent.? The only answer to this question that occurs to me is that Government have themselves grave doubts of the ability of the branch lines to pay 5 per cent. on the terms offered, and in consequence they consider it good business to put the risk of failure on the shoulders of others rather than to accept it themselves. Under such circumstances it seems to me that investors, both English and Indian, will show more wisdom by refusing the offer of the Government of India than by accepting it.

Mr. Priestley, to whom the foregoing letter has been submitted, writes as follows:—

Mr. Brunton gives three reasons for fearing that the 1910 rebate terms will be no more successful than those of 1893 and 1896. As his premises are not correct his conclusions are also wrong, and for the following reasons—

(1) The 1910 terms specifically limit the cost of working the branch to 50 per cent. of the branch's gross earnings.

(2) The main line is interested in working up the traffic of the branch because it divides equally with the branch all profits over 5 per cent. If, because of the extension of the branch into a through line, Government decide to take over the line before the expiry of the contract, they undertake to pay to the branch twenty-five times its average net earnings during the three years preceding the purchase subject to a *minimum* payment of Rs. 115 for every Rs. 100 of the branch's capital.

(3) It doubtless would give all the profit to Government if they raised the money and built the lines as State lines; but the financial advisers of the Government must be assumed to know their own business best, and if they find themselves unable to go to the market for a loan of all the money that is required for railway construction, there must be very good and sufficient reasons for their action. I am quite sure that there are no grounds for the very unworthy motive which Mr. Brunton attributes to Government, namely, that "Government have themselves grave doubts of the ability of the branch lines to pay 5 per cent. on the terms offered, and in consequence they consider it good business to put the risk of failure on the shoulders of others rather than to accept it themselves." I am equally sure that Mr. Brunton is wrong in the advice he offers to English and Indian investors that they "will show more wisdom by refusing the offer of the Government of India than by accepting it."

I believe, as I said in my paper, that the *terms* are on the whole good, and that lines promoted under them will prove perfectly satisfactory to investors, if the outlay is made to harmonise with the income expected; and in this view I am supported by Mr. L. R. W. Forrest, who has had larger experience than any man in India of the promotion of companies on these rebate terms.

TEA-GROWING IN RUSSIA.

The Imperial Russian Domain has an estate at Chakva, near Batoum, where successful experiments are being carried on in the cultivation of tea, oranges and other fruits, and bamboo. So far, it is said, no official reports on the results accomplished have been made public, but an exhaustive report is in preparation for an industrial exhibition to be held at St. Petersburg during 1912 and where the resources of the Caucasus will be exploited. The property consists of 43,200 acres, and covers what was formerly a hopeless tangle of rank vegetation. During the past few years a considerable portion of the territory has been cleared and improved, and has become one of the most attractive and healthful districts on the east coast of the Black Sea. The estate, according to the American Vice-Consul at Batoum, has a western frontage of about two miles along the sea. From there it stretches eastward, and is enclosed at its extreme limits by a semicircle of hills that give protection against the cold winds sweeping down from the mountains. The greatest altitude of the hills immediately surrounding the estate is about two thousand feet. The soil is principally red clay, black earth and sandstone. There is an occasional sprinkling of limestone. Tea-growing began on the estate in 1890. The most promising ground was cleared and the work put under the direction of expert tea growers. Members of the Imperial Domain's staff were sent to China, Japan, India and Ceylon to acquire practical knowledge of tea growing. Experienced growers were also brought out from China, and one of these still remains as manager of the tea plantations. Tea-growing has now passed beyond the experimental stage. The annual crop averages about two hundred thousand pounds. About twelve hundred acres are devoted to tea culture. The fields are partly on the plains and partly on the low hills, which in some cases have been terraced as a protection against erosion. During the early experimental stages about three thousand tea bushes were planted to the acre. This number has been increased, until as many as four thousand four hundred bushes are now crowded into the acre. The tea plantations are being extended at the rate of about one hundred and thirty-five acres per annum. The leaf is picked four times during the season. The first picking yields the superior quality, although the second is more abundant. The leaf is cured in a modern

Hosted by Google

factory, where every care is taken to obtain cleanliness. The cleaning, curling and packing are all done by machinery, which is mostly English. The sanitary conditions are excellent. The Chakva tea somewhat resembles in taste the teas of Ceylon and India, although it cannot be said as yet to have reached the excellence of the best of these. The Russian tea is sold principally in Poland and Central Asia. Shipments of about one thousand pounds have been sent to America on one or two occasions, but no regular demand appears to have followed.

PRODUCTION OF SILK IN FRANCE.

The production of silk and the number of sericulturists engaged in this industry in France, appear to have fallen off considerably during the last few years, judging from the following statistics published by the Minister of Agriculture:—

Year.	No. of Sericulturists.	Weight of Raw Cocoons.	
		Kilogs.	Lbs. avoirdupois.
1907	124,463	8,396,202	18,513,625
1908	123,804	8,409,299	18,542,504
1909	119,067	8,546,526	18,845,090
1910	114,283	4,269,709	9,414,708
1911	102,605	5,109,426	11,266,284

The principal departments in which this industry was carried on last year, and their production of raw cocoons, are given in the order of their importance:—

Department.	Kilogs.	Lbs. avoirdupois.
Gard	1,341,706	2,958,461
Ardèche	1,129,672	2,490,926
Drôme	962,122	2,121,479
Vaucluse	560,140	1,235,110
Var	327,745	722,678
Isère	234,974	518,118
Bouches-du-Rhône .	127,474	281,080
Basses Alpes . . .	116,772	257,482
Other Departments .	308,821	680,950
	5,109,426	11,266,284

THE PALM-SAP INDUSTRY OF THE PHILIPPINES.

The aboriginal Philippine tribes for hundreds of years—probably since long before the advent of white people among them—have made alcoholic drinks from the saps of certain palms, among them the nipa palm, the coco-nut palm, the sugar palm, and the buri palm. It has long been known that the sugar possibilities of some of these palms merited investigation. In fact, investigations into the sugar possibilities of some of them have been made in past years, notably into the merits of the coco palm in Ceylon and the sugar palm in Java, while sugar is now actually made from the coco palm by the natives of the Philippines. According to the returns of the Internal Revenue Bureau of the Philippines, about 93 per cent. of the entire output of alcohol and alcoholic beverages produced in the Philippines in 1910 came from the sap of palms, the production noted by the authorities amounting to about 2,062,000 proof gallons. The industry is greatly on the increase. About twenty-two beverages are manufactured from these saps. As a rule they are well-known native drinks, or imitations of well-known foreign drinks. The most popular, known as anisette anisado, vino de coco, and vino de nipa, contain 10 to 55 per cent. of alcohol. In addition to the above, a vast amount of palm sap is consumed without distillation. Nevertheless, the production of alcohol from these palm saps is developed to only a fraction of its possibilities. There are not only vast areas of palms suited to the production and accessible, which are yet untouched, but the cost of production, under even present crude conditions, is small, compared with the cost of producing alcohol from other sources. From the standpoint of alcohol production and of sugar production, the principal palm is the nipa palm. The nipa is an erect, stemless palm, of which the leaves and infloresence rise from a branched root stock, the leaves running from nine to thirty feet in length. It grows along the tidal marshes of rivers in low, wet lands, subject to overflows of brackish water as the tides rise each day, and it will not thrive where either fresh or sea water alone is available. Nipa swamps of considerable size occur practically throughout the Philippines, and, inasmuch as they occur in lands which otherwise are useless or almost without value, the cultivation of nipa palms where they are cultivated, or the presence of nipa trees wild where not cultivated, affords a profitable crop on little original outlay. The sugar-making possibilities of these saps, considered commercially, seem to hinge largely upon conditions under which the sap can be gathered and handled. The saps of the three principal sugar-bearing palms, the nipa, the coco, and the buri, run remarkably close together in composition. The sap from these trees, as a rule, is obtained through the flower stalk. In the nipa the flower stalk is cut off immediately below the fruit. It is generally tapped the fifth year. Each

Hosted by Google

day a thin slice is cut from the severed stem, to keep the wound fresh and facilitate the flow of sap. The sap is collected in bamboo joints hung on the stem, generally having a capacity of about two quarts. One stalk normally flows about three months, but it is not uncommon for it to be cut entirely away by the thin slices, from day to day, long before the flow has ceased. In some districts the plant is cut before the fruit forms, and the flow of sap is increased thereby, so far as daily output is concerned, but the length of the flow is shortened—the total yield of the plant apparently being about the same by either method. The plants are allowed to rest and put forth new fruit stalks, after being thus exhausted. How long they continue to bear is uncertain, but all authorities agree that a plant will continue to produce sap for many years, probably for fifty years or more, on an average. The yield of sap also is uncertain, and estimates vary between wide limits. An experienced distiller says that each plant will average about three pints daily. The yield and quality of the sap can be improved by seed selection and a measure of cultivation of the plant. The sap, as it flows, is clean and almost colourless, and very sweet to the taste. Fermentation commences so soon after the sap exudes that many distillers believe that yeast germs are present in the sap; but the immediate fermentation is explained, to some extent, by the fact that the receptacles for the sap are used, over and over again, without cleaning. When the sap is collected in clean vessels it undergoes no change for four or five hours.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Colonial Cotton.—A contribution of 75,000 bales of cotton goes but a short way towards the annual need of 18 million bales. Even the 100,000 bales which the British Cotton-Growing Association hopes to be raising in two or three years' time bulks hardly larger against the vast requirement of the world's spinning mills. Were this the sole outcome of nine years of labour, the sinking of hundreds of thousands of money and the raising of thousands of hopes, the failure might be written down as tragical. The fruits of the effort are fortunately very much larger, and although the time is not ripe to value them, some of their flavour can be appreciated. For one thing the association has determined authoritatively which parts of Africa are definitely unsuitable for cotton culture. The discovery has been made by costly experiment under the most skilled advice, and the proofs should be the means of saving future disappointment. The most favourable districts have been sorted out, their soil has been examined, and their special suitability to seed of one kind or another has been duly recorded. Native cultivators have been trained, and a market for seed cotton has been guaranteed to them. Ginneries have been established, and a cotton-growing industry has been set afoot in the best circumstances to ensure its continuance. The efforts have had excellent effects in stimulating other Governments to attend to cotton culture, and in reminding Americans that Europe is not content to rely too much on one source for its cotton supply. Negatively and positively, indirectly and directly, the outcome of the nine years amounts to very much more than a total production of three millionsworth of cotton. The British Government is a partner in the work and contributes £10,000 a year, under an agreement which expires in March next.

The late Sir Alfred Jones used to prophesy that Northern Nigeria would ultimately supply all Lancashire's needs. It supplied last season 2,500 bales, and the prospects are called splendid by the chairman of the association. Lagos yields 10,000 and Uganda 19,000 bales; there are besides Rhodesia, South Africa, Nyasaland, and the West Indies. India falls to the Indian Government's care, and in search of a really large new field the Cotton-Growing Association now addresses itself seriously to the Sudan. Money is wanted in sums commensurate with the possibilities of the area, and the British Government is asked for £200,000 as a grant in aid, and £1,000,000 upon loan for irrigation. The Sudanese scheme has the backing of eminent and responsible opinion in Lancashire, and the sympathy and interest of Lord Kitchener in Egypt.

Shuttle-kissing.—The practice of "shuttle-kissing," which has been reprobated but not utterly condemned by an inter-departmental inquiry, may be likened to stamp-licking. It is the most immediate and, at the same time, most unhygienic means of attaining a given result. The cotton or linen weaver seeking to draw the weft yarn through the shuttle's eye applies the shuttle to her lips, makes a sharp inhalation and so sucks out the thread. The weaver performs the act usually and may do it four or five hundred times a day in some circumstances, but there is a measure of promiscuity in shuttle-kissing. The male overlooker will kiss the shuttle when starting the loom, and the weaver's tenter, or assistant, will occasionally put the shuttle to her mouth. There is every probability that transmissible disease can be propagated by the shuttle, but the investigators have found no cases of infection proven. Particles of dust, dye, size and fibre are unquestionably brought into the mouth and throat, and perhaps into the lungs. The habit is highly probably a cause of the dental caries that is often conspicuous among weavers, but the evidence does not in sum impel the investigators to recommend England to follow Massachusetts and declare shuttle-kissing illegal. Their decision may well be disappointing to the considerable number of inventors who have been at pains to devise arrangements to supersede the human lips. The systems proposed by different patentees are several, ranging from simple syringes up to suction air-pipes, and including shuttles with

Hosted by Google

slits or eyes through which the yarn cannot be sucked. It is all too likely that shuttles which can more conveniently be kissed than mechanically threaded will be treated in the primitive manner, despite doctors, factory inspectors, laws and employers.

Indigo Dye.—The Textile Institute is addressing itself to the problems surrounding the use of the words "indigo" or "real indigo" on dyed cloth, with some view to standardising the term. A Scottish court has decided that the law cannot support the use of this word on goods into which no indigo enters, but otherwise all is vague. Apparently anything is indigo if the smallest part of that dye is used in its manufacture. There are blue wool serges that are indigo by courtesy of having passed through a spent indigo vat, and others that owe their title to the name purely to any such indigo as may have been used in dyeing the blue rags from which they have been manufactured. Does "indigo" imply vegetable indigo, or may it be applied to the indigotin synthesised from coal tar, which is much more used in these days than the leaf product? Can the word be justly used of any colour which responds to the accepted chemical tests? These are some of the points resting to be cleared, and it is worth observing that the dyeware manufacturer is able now to baffle most of the accepted tests. Once, the suspicious buyer was wont to rely upon the lemon-coloured green-ringed spot produced by putting a drop of cold nitric acid upon the cloth, but long before synthetic indigotin was a commercial product there were cheap blues sold to satisfy this test.

Real indigo has undoubted virtues in "feeding" the cloth upon which it is used, in withstanding exposure to all kinds of climatic conditions, and in rejuvenating its own colour after fading. The blue recovers its bloom if the garment is left to hang in the dark. To set against these advantages are the expense and the liability to rub or, as dyers say, to "crock." It is fair evidence that a blue is real indigo if the wearer's linen collar is blue-stained every time he wears the coat, and if the blue marks a handkerchief or screw of white paper when rubbed on the cloth dry. Just because indigo does "crock," and because the better the indigo the more the crocking, some highly expensive goods are dyed with alizarin blue. These cloths, which go to South America and other tropical countries, lead to no complaints of fading and none of rubbing.

Paper Yarn.—Paper yarn is perhaps best known to the public in the form of twine, although certain other uses have been found for it. To make it, paper is taken in such reels as are used in newspaper printing, and these are slit into ribbons which are twisted to form a continuous round thread. The thread may be glazed or polished for use as parcel twine, and be reinforced inwardly with a thread of flax. The article has appeared as a substitute for jute in making bagging; it has been used for insulating electrical wires, and for making a backing or foundation for cheap carpets. These are the more commercially practicable purposes to which paper yarn has been put, although it has been exhibited in some other connections. Coarse mattings resembling cocoanut matting, white duck serviceable for shoe-uppers, woven towels for steamship use, webbing for the ends of braces and for upholstery, are some of the less far-fetched employments that have been proposed for it. By way of *tour de force* it has been shown that paper thread can be used underneath a facing of silk to make hatbands, and that passable imitations of Irish tweed can be woven with alternate threads of shoddy and paper. These varied capabilities have not averted financial troubles from some of the producers, and the total production, viewed on the general scale of textile things, is small. Opinions may vary as to which is the greatest among the natural defects inherent in a coagulated mass like paper yarn, but an obvious one is sheer thickness. Four's cotton counts (840×4 yards per lb.) are fine in paper yarn, and 6's or 8's are the finest counts mentioned as practicable. In the cotton trade, 40's are reckoned a coarse count, and the best cotton spins to 300's. By no possible means can coarse yarn fill the place of fine. The deadness and inelasticity of paper, its softness when wet, its liability to fray when dry, the ready fading of its colours, and half a dozen other considerations, incapacitate paper from competing on level ground with the fibrous materials, and restrict its use to a narrow textile sphere.

English Wool.—Another difficult year is expected by dealers in the English clip. The British farmer stands firmly to his prejudices in favour of high prices, and refuses to be daunted by the demonstrable fact that Colonial crossbred wool of sorts closely resembling his own is being dealt in at substantially lower prices. It is little to him that dealers have not for two seasons past made more than their living expenses. He is aware that wool is grown in Australasia and South America on sheep of his own breed and strain, and that this arrives in large quantities, carefully packed, regular in quality and requiring much less sorting and manipulation than his own. The facts are an old story, and time only makes it more clear that British-grown wool of nominally the same quality possesses some superior attractions that are to be set against its manifest disadvantages. The wool is more "lofty," as the expressive term goes for bulkiness and springiness, and it is more lustrous. For its own range of purposes the home supply is unexcelled, and no imported wools exactly fill its place. The farmer has an incentive to be firm this year in his knowledge that the clip—at least of hogg wool—will be short. Last year's dry summer, with its consequent lack of winter feed, induced many farmers to part with the lambs that would have normally become yearlings. Hogg

Hosted by Google

(*i.e.* first) wool will doubtless be dear relatively to wether wool (the produce of animals which have been previously shorn), and it will assuredly pay growers to pack the two kinds separately.

CORRESPONDENCE.

COLONIAL VINE CULTURE.

It does not seem to be sufficiently appreciated in this country that the climatic conditions and soil over large areas in Canada have been demonstrated to be as highly adapted for vine culture as the best known vineyard districts in Europe which have a world-wide reputation. Fruit-growing in Canada in the popular mind is associated with the raising of apples, pears, and the hardier fruits. It is true grape-growing at present is perhaps of local rather than of national importance; but of the possibilities to be realised in the cultivation of the vine in Canada there can be no question. Grape-growing centres in the province of Ontario, whose vineyards cover 12,000 acres. This province has a larger variety of local climate than any other country of similar extent in the world, due to the influence of the Great Lakes and to the hydrographic system of the interior. Between the north shore of Lake Superior and Lake Erie the summers vary from those of Scotland to those of central and much of southern France—summers as warm as in northern Italy and warmer than the coast of Portugal. The most favoured sections lie along the shores of Lake Ontario and Lake Erie, including the Niagara Peninsula. According to expert opinion, there is an area of some 9,000 *square miles* in Ontario where even peaches of one kind or other can be successfully grown in the open air, while in the whole valley of the St. Lawrence there is an area of probably 30,000 *square miles* where the soil and climate are suited for the vine. The Niagara district and the counties along Lake Erie are the natural home of the famous Concord grape-vine, the variety with which the vineyards of France and Italy and other countries have been re-stocked after the ravages caused by phylloxera. In this region the counties of Lincoln, Wentworth, and Welland are mainly identified with grape-growing, and have a total annual output of from 20,000 tons. The vine begins bearing at four years, and continues for a lifetime. The vines are grown on trellis supports. Good grape land is plentiful. In the most favoured districts it may be purchased at from £16 an acre.

The figures furnished by the Ontario Government of the cost of maintenance and the profit per acre are as follows:—Cost of bringing an acre of grapes into full bearing, including supports for vines, £15; annual outlay per acre when bearing (pruning and tying, cultivation, spraying three times, picking, and packages and delivery to stations), £12; average yield, three tons (or 750 baskets, average price 7½*d.*), £23 (a yield of five tons per acre is frequently obtained); net return per acre, £11.

Grapes for the table are mainly raised; but about one-third of the grape crop is devoted to the manufacture of wine, the annual output being 300,000 gallons, for which purpose the grower is able to dispose of his crop at from £3 14*s.* to £7 8*s.* per ton, and finds it a profitable method, as everything can be shipped. Plants for wine manufacture exist at St. Catharine's, Hamilton, Stanford (near Niagara Falls), and at Sandwich and Pelee Islands in Essex Co. The markets for table grapes are Toronto, Hamilton, and other neighbouring cities. Grapes are also shipped by the carload to the western and eastern provinces. It may be pointed out that grape-growing at present is conducted in connection with other forms of fruit-growing, and with the raising of vegetables and tobacco. Mixed horticulture of this character is growing very rapidly in Ontario, and attracting large numbers of people from this country who prefer intensive cultivation on small areas amid the amenities and comforts of life in well-ordered and settled districts to the possibly more profitable openings to be found under pioneer conditions in Western Canada. C. F. JUST.

NOTES ON BOOKS.

MODERN COTTAGE ARCHITECTURE. Selected and Described by Maurice B. Adams, F.R.I.B.A. Second Edition. London: B. T. Batsford. 10*s.* net.

In preparing this volume, Mr. Adams has selected with great care a series of views and plans representing practically every type of cottage—"single cottages, cottages in pairs and in rows, gardeners' cottages, bailiffs' cottages, week-end cottages, a nurse's cottage, a doctor's cottage, a cottage hospital, and a cottage home, lodges, gate-entrances, etc., built in stone, brick and half-timber, with roofs in thatch and tiles, and walls tile-hung or rough-cast." The designs include the work of most of our best-known architects, *e.g.*, Sir Aston Webb, Sir Ernest George, Sir R. S. Lorimer, Messrs. E. L. Lutyens, A. N. Prentice, Guy Dawber, Leonard Stokes, the Editor himself, and many others. In this, the second edition, the number of illustrations — which are admirably reproduced—has been largely increased, so that there are now no fewer than 83 full-page plates from photographs and drawings, and 54 illustrations of plans, elevations, etc., in the text.

Mr. Adams contributes an introductory chapter entitled "Notes concerning Cottage Building," in which he gives some useful hints as to planning, arrangement, and fitting generally; but the most valuable part of the book, no doubt, consists in the illustrations, which represent types of cottages suitable for almost every part of England and Scotland. Anyone who meditates building a cottage of whatever description would do well to start operations by consulting this interesting and suggestive book.

Hosted by Google

STEAMSHIP NAVIGATION. By H. T. Arnold. London: Blackie & Son, Ltd. 1s. 6d.

In this little handbook, Mr. Arnold gives a brief but very clear account of the elements of steamship navigation. After a section of definitions, he describes various patent ship-logs, Walker's current meter, and Lord Kelvin's sounding machine. Chapter II. deals with swinging the ship and the correction of courses; Chapter III. with the differences of latitude and longitude, and the succeeding chapters with plane sailing, traverse table and traverse sailing, parallel sailing, middle-latitude sailing, Mercator's sailing, the day's work, and, finally, the construction of a Mercator's chart. A number of practical examples and examination tests are given, which should make the book useful to students in nautical schools.

GENERAL NOTES.

ROYAL LOAN OF INDIAN OBJECTS TO THE VICTORIA AND ALBERT MUSEUM.—The King and Queen have been graciously pleased to lend to the Victoria and Albert Museum an important series of Indian objects, including caskets and addresses presented to their Majesties on their recent visit to India, and gifts from the Maharaja of Nepal, the Begam of Bhopal, and the Sultans of Lahej, and of Shehr and Mokalla. The collection has been arranged in Room 1 of the Indian section, where it will remain on view until further notice. The caskets, designed to contain the addresses presented to their Majesties, are of native manufacture in a style which is largely European. The most important is that presented by the Municipal Committee of Delhi; this is in ivory, with panels beautifully carved with scenes illustrating the Ramayana, one of the great epic poems of the Vedic age. Another interesting casket is that of the Presidency of Madras, consisting of a rectangular structure in silver supported on kneeling elephants, and surmounted by peacocks with enamelled plumage. The gift of the Municipal Corporation of the City of Bombay, also of silver, suggests in form a Dravidian temple, flanked by domes of Mohammedan type. The casket from the Begam of Bhopal is the model of a river boat with eight rowers and a steersman; it is in silver-gilt with a string of small jewels along the gunwale. The present from Nepal consists of a variety of objects in which figure interesting specimens of native wood-carving, brasswork and gold jewellery. With one or two exceptions, these are skilful products of the Newar craftsmen, the race of mixed Indian and Mongolian origin which formerly supplied Nepal with a dynasty of Rajas overthrown by the Gurkhalis in 1767. The miniature windows, intricately carved in Himalayan red birchwood, illustrate what is at present the most important form of Nepalese decorative art.

FERTILITY OF THE SOIL.—In a paper on "Recent Advances in Agricultural Science," with particular reference to the fertility of the soil, recently read before the Royal Institution, Mr. A. D. Hall, F.R.S., said that the fertility of the soil was the outcome of a very complex series of factors, including the actual supply of plant food in the soil, its mechanical texture as conditioning the movements of water, and the particular micro-fauna and flora inhabiting the soil, for upon these lower organisms depended the facility with which the material contained in the soil became available for the nutrition of the plant. Dealing with the question of the duration of the fertility of the land under continual cropping, the lecturer said that the United States had begun to take alarm about the reduced production of some of its most fertile lands, as, for instance, the old prairie lands of the Middle West—a reduced production which, among other causes, had helped to set in motion a stream of migrants from the United States to the newer lands of the Canadian North-West. In the development of agriculture three distinct stages might be observed. There was the pure exploitation of the initial resources of the soil, when the farmer was to all intents and purposes mining in its fertility. This was the process which had been going on in America and in all the newer countries. Farming of that kind was destructive; but in the older lands of the west of Europe, which had been long under cultivation, a conservative system had been devised which was capable of keeping up the productive power of the soil, though not, perhaps, to a very high pitch. The best example of this could be seen in the Norfolk four-course rotation before the introduction of artificial fertilisers. This conservative farming, about 1840, began to give place to the third stage in the development—intensive farming —rendered possible by the discovery of artificial fertilisers and the cheap freights which brought cheap feeding-stuffs to the soil of this country. By these means the average production of the land of the British Isles had been raised from the twenty bushel level to something over thirty bushels, and the most intensive farmers reached an average level at least 25 per cent. higher. In their case the soil had become practically a manufacturing medium, transforming the nitrogen and other fertilising materials added to it into crops, giving nothing to those crops from its original stock, and, indeed, up to a certain point gaining rather than losing fertility with each year's cultivation. The research work of Doctors Russell and Hutchinson at Rothamsted justified them in believing that they could so rearrange the micro-fauna and flora of the soil as to obtain a much higher duty from the reserves of nitrogen contained in them.

COTTON IN SIAM.—It was thought at one time that cotton might be profitably grown in Southern Siam, but recent experiments are not very encouraging. A Japanese syndicate was formed with the object of cultivating cotton, but its operations have not been successful, and the local exhibits at

Hosted by Google

the recent exhibition of agriculture and commerce in Bangkok were pronounced to be generally poor. Mr. Acting-Consul Crosby, in his report on the trade of Bangkok, seems to think that the introduction of superior varieties from other countries may be productive of good results, but the high cost of labour is a severe handicap to planters. Experiments have been tried with Egyptian cotton, but the results have not been very satisfactory, the staple turning out little better than that of local varieties. It may be noted that of the imports of cotton goods the United Kingdom and Singapore contributed, last year, 36 and 35 per cent. respectively.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 3...Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Engineers, Society of, at the Institution of Electrical Engineers, Victoria-embankment, W.C., 7.30 p.m.

Chemical Industry (London Section), Burlington House, W., 8 p.m. 1. Dr. H. E. Armstrong and Mr. R. T. Colgate, "The Nature of the Process of Oxidation (with demonstrations)." 2. Mr. E. G. Clayton, "Some Present-day Aspects of the Match Industry."

Actuaries, Staples Inn Hall, Holborn, W.C., 5 p.m. Annual Meeting.

Victoria Institute, 1, Adelphi-terrace, W.C., 4.30 p.m. Ven. Archdeacon Beresford Potter, "The Influence of Babylonian Conceptions on Jewish Thought."

Surveyors, 12, Great George-street, S.W., 5 p.m. Annual General Meeting.

TUESDAY, JUNE 4...Royal Institution, Albemarle-street, W., 3 p.m. Professor W. M. Flinders Petrie, "The Formation of the Alphabet." (Lecture II.)

Alpine Club, 23, Savile-row, W., 8.30 p.m. Mr. W. R. Caesar, "Mont Blanc by the Brenva and other Traverses in 1911."

Photographic, 35, Russell-square, W.C., 8 p.m. Mr. H. W. Bennett, "Minor Difficulties in Architectural Photography."

Zoological, Regent's Park, N.W., 8.30 p.m. 1. Mr. E. G. B. Meade-Waldo will introduce a discussion on "The Preservation of the English Fauna." 2. Mr. R. Lydekker, "The North Rhodesian Giraffe." 3. Professor S. J. Hickson, "On the Hydrocoralline Genus *Errina*." 4. Dr. Frank E. Beddard, "Contributions to the Anatomy and Systematic Arrangement of the Cestoidea. VI.—On an Asexual Tapeworm from the Rodent *Fiber zibethicus*, showing a new form of Asexual Propagation, and on the supposed Sexual form." 5. Helen L. M. Pixell, "Polychæta from the Pacific Coast of North America. Part I.—Serpulidæ, with a Revised Table of Classification of the Genus *Spirorbis*." 6. Dr. R. Broom, "On some new Fossil Reptiles from the Permian and Triassic Beds of South Africa."

WEDNESDAY, JUNE 5...Geological, Burlington House, W., 8 p.m.

Public Analysts, at the Chemical Society's Rooms, Burlington House, Piccadilly, W., 8 p.m. 1. Mr. H. D. Richmond, "The Composition of Milk." 2. Messrs. A. Chaston Chapman and Alfred Siebold, "On the Application of Adsorption to the Detection and Separation of certain Dyes." 3. Mr. W. F. Lowe, "The Estimation of Dirt in Milk." 4. Mr. E. H. Miller, "A New Method for the Detection and Estimation of Small Quantities of Nitrous Acid." 5. Mr. F. S. Sinnatt, "A Further Note on the Use of Methylene Blue as an indicator in Iodimetric Titrations." 6. Dr. K. J. P. Orton, "The Estimation of Nitric and Nitrous Acids in Acetic Acid Solution. The Stability of Nitric Acid in Acetic Acid Solution."

Royal Archæological, at the Society of Antiquaries, Burlington House, W., 4.30 p.m.

THURSDAY, JUNE 6... Water Engineers, Institution of, Town Hall, Cheltenham (Summer Meeting), 10 a.m. 1. Address by the President, who will also supply "Description of the Cheltenham Corporation Waterworks." 2. Dr. S. Rideal, "The Pre-Filtration Process now being introduced at the Tewkesbury Works." 3. Selection from the following papers :— (*a*) Mr. P. Griffith, "The New Waterworks for Skegness"; (*b*) Mr. D. Dinwiddy, "The Rating of Water Undertakings"; (*c*) Mr. A. Valon, "The Rating of Water Undertakings"; (*d*) Discussion upon "The Desirability of Standardising the 'General Conditions of Contracts,'" introduced by Mr. H. W. Woodall; (*e*) Mr. E. H. Crump, "The Hinckley Waterworks"; (*f*) Mr. R. Read, "The Gloucester Waterworks (Witcombe Reservoirs)"; (*g*) Mr. G. Embrey, "The Use of Sulphate of Copper in purifying Water Supplies"; (*h*) Dr. J. H. Garrett, "The Self-Pollution of Water by Natural Growths"; (*i*) Mr. L. Richardson, "The Geology of Cheltenham with special reference to the Water Supply."

Linnean, Burlington House, W., 8 p.m. 1. Professor A. Meek, "The Development of the Cod, *Gadus morrhua*, Linn." 2. Mr. E. J. Bedford, "Lantern-slides of Orchids recently observed in Sussex." 3. Mr. C. Hedley, "Palæontographical Relations of Antarctica." 4. Mr. R. Vallentin, "Lantern-slides illustrating the Fauna and Flora of the Falkland Islands."

Chemical, Burlington House, W., 8.30 p.m. 1. Mr. J. E. Purvis, "The Absorption Spectra of Various Derivatives of Naphthalene in Solution and as Vapours." 2. Mr. J. Kendall, "The Velocity of the Hydrogen Ion, and a General Dissociation Formula for Acids." 3. Messrs. F. D. Chattaway and A. E. Swinton, "Chloroamino Derivatives of Benzylidene Diamides." 4. Messrs. T. S. Price and D. F. Twiss, "The Refractivity of Sulphur in various Aliphatic Compounds." 5. Messrs. H. M. Dawson and F. Powis, "The Conditions of Iso-Dynamic Change in the Aliphatic Ketones. I.—The Auto-Catalytic Reaction between Acetone and Iodine." 6. Messrs. C. Smith and W. Lewcock, "Pyrogenic Decompositions. I.—Benzene." 7. Messrs. P. C. Ray, N. Dhar and T. De, "Vapour Density of Ammonium Nitrite." 8. Messrs. H. Stephen and C. Weizmann, "Tyrosin and its Derivatives Containing Substituents in the Benzene Ring." Preliminary note.

Royal Institution, Albemarle-street, W., 3 p.m. Professor C. G. Barkla, "X Rays and Matter." (Lecture II.)

FRIDAY, JUNE 7...Waterworks Engineers, Institution of, Town Hall, Cheltenham. Summer Meeting (continued).

Royal Institution, Albemarle-street, W., 9 p.m. Sir William Macewen, "Lord Lister."

Municipal and County Engineers, Institution of, Albert Hall, Stirling (Scottish District Meeting), 11 a.m. 1. Reception. 2. Discussion on paper by Mr. A. H. Goudie, "The Municipal Works of Stirling." 3. Discussion on paper by Mr. D. R. Cox, "Work carried out in Central Stirlingshire under the Road Development Grant."

SATURDAY, JUNE 8...Waterworks Engineers, Institution of, Town Hall, Cheltenham. Summer Meeting (continued).

Royal Institution, Albemarle-street, W., 3 p.m. Mr. W. L. Moore, "The Weather and the Utilities of Forecasts."

Hosted by Google

Journal of the Royal Society of Arts.

FRIDAY, JUNE 7, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICE.

THE SOCIETY'S ALBERT MEDAL.

The Albert Medal of the Society for the current year has been awarded by the Council, with the approval of His Royal Highness the President, to the Right Hon. Lord Strathcona and Mount Royal, G.C.M.G., G.C.V.O., LL.D., D.C.L., F.R.S., for his services in improving the railway communications, developing the resources, and promoting the commerce and industry of Canada and other parts of the British Empire.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A meeting of the Colonial Section was held on Tuesday, May 21st, 1912; The Right Hon. Lord Emmott, Under-Secretary of State for the Colonies, in the chair.

The Chairman, in introducing the reader of the paper, said Mr. Jenkins had performed many services to the State of South Australia and to the Empire. He was Prime Minister of South Australia for four years, and was subsequently Agent-General for that State in this country for another four years. Before he filled those high offices he was Minister for Works for some years, and during that time had great experience of railways, and made a special study of them. The audience, therefore, would hear a paper of great interest.

The paper read was—

AUSTRALIAN RAILWAYS.

By The Hon. J. G. Jenkins.

After I consented to read a paper on Australian Railways, one of my friends said to me: "Why in the world did you choose such a subject? You must have known that it was dry and unattractive, and would be most uninteresting to anyone who would be foolish enough to go and listen to you." Buoyed up by such encouragement, I decided to continue the paper.

There are three reasons why I have selected this subject, dull and dry though it be. In the first place, it is a subject in which I have for many years taken a special interest, partly by choice and partly by compulsion, as I was for nearly twenty years interested in every railway proposal or Bill which was brought before one of the Australian Parliaments, and was for over six years the Ministerial head of the railway department.

In the second place, my experience during several years in this country has on many occasions convinced me that there is a great lack of knowledge by the general public in respect to the relations between the indebtedness of Australia and its public undertakings, such as railways, wharves, waterworks, etc.; and the third reason is that the energetic Secretary considered the subject a good one, and his judgment and experience is beyond dispute.

Area and Population.

In dealing with Australian railways, it may be necessary to refer for a moment to the country's location, extent, physical features, and climatic conditions.

We have a continent island, lying at the other end of the world, over 10,000 miles from the kingdom from which 95 per cent. of its population has descended; having an area of about three million square miles and a coast-line of over 12,000 miles, with for the most part a fringe of hills or low mountains not far from the coast, with vast plains and table-lands broken by occasional hills in its expansive interior, with a variety of climate, tropical, semi-tropical, and temperate, a rainfall varying according to locality from five to nearly 200 inches, rich soil, and glorious sunshine.

Such, in brief, is Australia, with a population of $4\frac{1}{2}$ millions of people, or only one and a half for every square mile of land, while here in the

Hosted by Google

United Kingdom we have 366 for every square mile.

These are facts which have to be noted when dealing with a country's railways.

Construction of First Railway.

The first railway was started in New South Wales in 1850 by a private company, but the discovery of gold in different parts of Australia about this time caused a general rush of nearly every able-bodied man to the goldfields, so the private company were not able to complete their railway. The same thing happened with one or two private companies in Victoria about the same time, and in both Colonies appeals were made to the authorities, and the lines were taken over and completed by the respective Governments, so it is more than likely that the State-owned railways of Australia are the result of the gold discoveries, for from these early experiences other lines were proposed and constructed by the Governments of the different States, and the national system has grown up with the population.

A few private lines have been built, but they have mostly been purchased by the Governments. So, in speaking of Australian railways, it is generally understood that one means Government-owned lines.

Slow Growth and Cost.

For many years the railway growth was very slow. In 1855, five years after the commencement of the first line, there were only twenty-three miles in all Australia, and during the next sixteen years, up to 1871, there were only 220 miles more added. From 1871 to 1891, however, 9,000 miles were constructed, and each year since has added to the mileage, until on the 30th June last year there were about 17,000 miles of Government railways, which had cost about £155,000,000, or an average of a little over £9,000 per mile.

When this is compared with the great expense of railway construction in this country, it is easy to see that the money spent on railways in Australia is bound to earn a good return as population and settlement increase.

Some of the Australian lines have been rather expensive, the dearest one being from Melbourne to Bendigo, one hundred miles, which was built just fifty years ago at a cost of £48,000 per mile. On the other hand, many lines have been built in the different States at less than £2,000 per mile, and I believe one or two lines in West Australia have only cost about £1,000 per mile. These cheap lines have been the means of opening up and developing large tracts of country which would otherwise have remained unoccupied.

The money for the construction of the railways has been mostly raised by loan in this country, each particular State dealing with its own lines and becoming responsible for the money borrowed.

Negotiations for Control.

On several occasions since the establishment of the Commonwealth Government, negotiations and discussions have taken place between the Federal Government and the States to see if arrangements could be made for the State loans to be taken over by the Federal Government, giving that Government the receipts from the railways, and in a sense a kind of general control. So far no successful basis has been arrived at, and until the Federal authorities become more national and practical, and less sectional and political, it is considered that the States will act wisely to retain the responsibility and the control.

A mutual understanding has existed for years between the Railway Commissioners of the different States, and the most harmonious relations prevail.

Details of each State.

The mileage, cost, and earnings of the railways in each State are of special interest, more particularly to those who are holders of Australian bonds.

New South Wales has 3,760 miles of Government railways, which have cost £51,000,000, or an average of £13,550 per mile. The gross earnings last year were £6,042,000, and after paying working expenses and full interest on capital, there was a surplus to pay into the State Treasury of £554,000. This was not an exceptional year, for during the six years ending June 30th, 1911, there was a net surplus of over £3,000,000.

In Victoria there are 3,528 miles of railways, which have cost £44,200,000, or an average of £12,500 per mile. The gross earnings for the year ending June 30th, 1911, were £4,900,000, and after paying working expenses, interest on capital, and over £100,000 for pensions and gratuities, they had a net profit of £283,000, and for the six years ending June 30th, 1911, they had a net surplus of over £900,000.

South Australia has 1,457 miles of railways, which have cost £12,680,000, or an average of £8,700 per mile. The net surplus last year was £312,000, and for the last six years it was £1,388,000.

Queensland has 4,248 miles of railways, the most of any one State; they have cost

Hosted by Google

£27,300,000, or an average of £6,425 per mile. Total revenue for year ending June 30th, 1911, £2,882,000; net surplus, after working expenses and interests, £163,500; net surplus for the previous year, £218,000. For some years previous the returns had not been sufficient to pay full interest after working expenses.

Western Australia constructed its first railway in 1879, for the development of the copper mines in the Northampton district; since that time the discovery of rich mineral fields has been a great impetus to railway construction. Up to the 30th June, 1911, there were 2,633 miles of Government railways open for traffic; they had cost £12,000,000, or about £5,000 per mile, being the cheapest in any of the States. The gross revenue for the year was £1,844,000, after paying working expenses and interest on capital, leaving a net surplus of £224,500, and for the six years ending June 30th, 1911, £884,000.

Tasmania has 463 miles of railways, which have cost £4,000,000, or an average of £8,650 per mile. Tasmania is the only State that has not in recent years been earning a net surplus over and above working expenses and interest on expenditure, but her losses have been small in comparison with the profits in the other States, and the prospects of further traffic over the railways there are encouraging. The railway manager in his last report says:—

> "At the time of writing there is great activity on the west coast lines consequent on the resumption of work at the Zeehan smelters, and there is also a marked improvement in the traffic on the western and main lines. Reports from all districts are very encouraging as to the coming harvest, and I confidently anticipate a large increase in revenue for the current year."

Taking the railways in the Commonwealth as a whole, the net surplus over working expenses and interest on capital for the last six years has been over £4,200,000.

It seems, therefore, that there need be no doubt about the safety of the money lent to Australia for railway construction.

Australia's Debt.

When Australia's indebtedness is referred to as so much per head of the population, without explanation it looks as if it was a debt-ridden country; but when it is explained that out of the entire indebtedness of between 250 and 260 million pounds, 25 per cent. of it is lent by its own people, whose knowledge of the security is first-hand, and that 155 million has been spent on railways which have paid back to the revenue in surplus profit an amount of over £700,000 each year for the last six, the national debt appears in a different light.

Besides this, wharves, waterworks, electric tramways, and other public undertakings are returning a fair rate of interest and increasing in value each year.

While referring to assets, it might not be out of place to mention, without dealing with the immense wealth of pastoral, agricultural, manufacturing, and mining industries, that the people have sufficient money deposited in the Savings and other banks to pay off the entire cost of the railways, and still have about twenty million pounds to spare for holiday and travelling expenses.

Railway Administration.

The Australian States have adopted a somewhat uniform system so far as the administration of their railways is concerned.

Prior to 1888, New South Wales railways were vested in the Minister for Works; in that year an Act was passed to place the control under Railway Commissioners, in order to free them from political influence. Three Commissioners were appointed, but the triple-headed control did not prove altogether satisfactory, so one Chief Commissioner was appointed under an amended Act of 1906.

In Victoria, even at an early date, the necessity for removing the control from political influence was felt, and in 1883 Commissioners were appointed by Act.

Queensland and South Australia adopted the same system in 1888.

Western Australia in 1902 followed the example of the eastern States, and placed its railways under the control of a Commissioner.

In Tasmania, where the Government railways are not extensive, the control was, until recently, vested in a Minister, but the Act passed last year followed the example of the other States, and placed the control under a Railways Commissioner.

No one can doubt the wisdom of placing the control and management of the railways under Commissioners instead of allowing them to remain under political control.

Of course, railway matters are still discussed in Parliament, for no line can be constructed without an Act authorising it; money can be voted only by Parliament, and important regulations and alterations of rates have to be laid on the table of the House for a time before they become effective.

All this gives members who represent railway

Hosted by Google

districts ample opportunity of mentioning real or supposed grievances, and generally talking to their constituents at the public expense, an art not unknown even at Westminster.

CONSTRUCTION.

Time will not permit of my dealing with the engineering and other difficulties in the construction of the railways. From what was previously stated, that a fringe of hills or mountains in many places separates the coast from the interior, it will be seen that much expense and skilful engineering were necessary for the construction of many of the lines. Special mention might be made of those leading out of Sydney, west over the Blue Mountains, north over the Hawkesbury River, and south through the Bulli Pass. The Toowoomba line in South Queensland, and the Cairns line in the north, were by no means easy to construct; neither was the line leading through the hills from Adelaide towards Melbourne.

Of course, there are no curves on the Australian lines so sharp as they are supposed to be on American tracks, where the brakesman on the back car is said to be able, while going around the curve, to light his pipe from the engine-driver's fire. Some of the Australian curves are sharp enough, however, occasionally to give the passengers the sensation of a real sea voyage.

Later on, when some views are shown of the country through which the lines pass, a better idea will be given of the work needed to construct them.

BREAK OF GAUGE.

When the first line of railway was authorised in New South Wales, the Colonial Office, which at that time was under Mr. Gladstone's control, sent out a despatch urging the adoption of the 4ft. 8½in. gauge; but the engineer was strongly in favour of a 5ft. 3in. gauge, and it was started on that basis. Victoria and South Australia also started on that gauge. There was a change of engineer in New South Wales before much work was done, and the new man reverted to the original suggestion of 4ft. 8½in., and all the railways in New South Wales have been constructed on that gauge, while all Victorian lines are 5ft. 3in. gauge. South Australian lines are partly 5ft. 3in. and partly 3ft. 6in. All the lines in Queensland, Western Australia, and Tasmania are 3ft. 6in., while the lines taken over by the Commonwealth from the South Australian Government are also 3ft. 6in. gauge, so at the present time Australia unfortunately has three different gauges—3,760 miles, 4ft. 8½in.; 4,151 miles, 5ft. 3in.; and 8,815 miles, 3ft. 6in. gauge.

The question of adopting a uniform gauge has been discussed for years, and the inconvenience and annoyance to travellers under the present system are frequently mentioned, and generally magnified. There is not much, however, to complain about, for you can travel from Longreach, in Queensland, to Oodnadatta, in South Australia, a distance of 3,300 miles, passing through Brisbane, Sydney, Melbourne, and Adelaide, the four principal cities of Australia, and you need only change on account of the break of gauge three times, first on the border of New South Wales and Queensland; second, at Albury, between New South Wales and Victoria; and third, at Terowie, 150 miles north of Adelaide.

The great bar to the adoption of a uniform gauge is the heavy expense in the alteration of the roadway and in the rolling-stock. The cheapest system to adopt would be the 3ft. 6in., but that is not likely to take place. The next least in expense would be the 4ft. 8½in., as all the roadway of the 5ft. 3in. would answer by moving the rails, and many of the cuttings and tunnels even on the 3ft. 6in. would be wide enough for the 4ft. 8½in. line. I notice, by recent reports, that the Commonwealth Government have decided upon this gauge for the transcontinental line from Port Augusta to Kalgoorlie. This will mean a break of gauge at each end of the line, unless South and West Australia alter their gauges accordingly, which is not likely for some years to come.

LINES OWNED BY THE COMMONWEALTH.

By the transfer of the Northern Territory from the South Australian Government to the Commonwealth the Federal Government have become the owners of two railways, one from Port Augusta to Oodnadatta, a distance of 478 miles, and the other from Port Darwin to Pine Creek, 145 miles; both lines are on the 3ft. 6in. gauge.

These lines, 623 miles in all, have cost £3,420,000, or about £5,500 per mile.

The general understanding on which the Northern Territory was transferred to the Commonwealth was that the Federal Government should construct two transcontinental railways, one connecting West Australia with the east by constructing a line 1,050 miles long from Kalgoorlie to Port Augusta, the other to connect the Northern Territory with the south by building a line about the same length from Pine Creek to some point on the Port Augusta line.

Hosted by Google

The route of the first of these lines from east to west has been agreed upon, the survey made, and work is soon to commence. Unfortunately, there appears to be some misunderstanding over the proposed route for the Northern Territory line.

It was generally understood, when the Territory was transferred, that this proposed line would run from Pine Creek in the north to Oodnadatta in the south, to connect with the South Australian lines. Some different opinions were expressed about the interpretation of the agreement, but both Governments at the time said there was no necessity for doubt. It now seems as if there was great reason for the doubts expressed, for, judging by the recent reports from Australia, the present Prime Minister, Mr. Fisher, seems more favourably inclined to connect the Pine Creek Railway with the Queensland lines than he is to take the direct and generally understood route straight across the continent from north to south; and it is questionable whether any assurance will be given to the South Australian Government in reference to the matter for some time, especially as there is a general election for the Commonwealth Parliament within twelve months.

If the line is carried to the east, as suggested, and the centre of Australia is left without a railway, the people of South Australia will deeply regret that clearly-defined conditions were not insisted upon before the Territory was transferred.

The estimated cost of the construction of these two transcontinental lines is between four and five million pounds each, or, roughly speaking, about £9,000,000; this, added to the $3\frac{1}{2}$ million liability on the lines already taken over by the Commonwealth, will amount to £12,500,000.

From purely a railway point of view, it is not likely that these lines would prove, for some years to come, payable undertakings. There are, however, two strong reasons for the work.

In the first place, all military authorities for years have urged the necessity of these lines for defence purposes, more especially the line to connect Port Darwin with the south, thus affording the opportunity of direct communication with a naval base in the north, where it would be most likely to be needed in time of attack.

The second strong reason more particularly for the north to south line is that the Commonwealth, having taken over the Northern Territory, have on their hands 335 million acres of practically undeveloped and unoccupied land, nearly four and a half times as much as the United Kingdom with its population of forty-five million, while this vast territory is populated by about 1,000 whites, less than 2,000 Chinese, and a few thousand aborigines.

This vast tract of land can only be properly settled and developed by opening up means of ready communication and transport, and Australia is now realising this fact more clearly than it did years ago; and those who have watched the aggressive progress of the Eastern countries, with their overcrowded millions, must see the necessity for speedy development and settlement in Australia.

Australia's Prosperity.

The great prosperity of Australia during the last few years has given a decided impetus to railway construction, and to-day there are more miles of railway in course of construction, and projected, than at any previous time in its history. Many of these lines, in Queensland, Western Australia, and South Australia, are being cheaply constructed as feeders to main lines, and to open up the pastoral and agricultural lands.

It is well to note here that by the use of artificial manures and more scientific farming, millions of acres are now being settled as agricultural land which a few years ago were only considered fit for pastoral purposes, and some of them but of little value even for pasture.

Private Railways.

In addition to the Government railways, there are about 1,200 miles of private-owned lines in Australia, about half of which are used for passenger as well as goods traffic, while the other 600 miles are used chiefly for carrying minerals and timber. The capital cost of these lines is between three and four million pounds.

Tramways.

The electric tramways of New South Wales belong to the Government, and in South Australia the Government principally control them in conjunction with the municipal authorities.

In the other States the tramways belong to private companies, but will eventually become the property of the corporations. Melbourne has the cable tramway system, and, owing to its expense in construction, it has not extended to the surrounding suburbs to the same extent as the suburban railways have, which the Victorian Government now propose to electrify.

Hosted by Google

State Ownership.

There has always been a division of opinion in reference to the advisability or otherwise of State-owned railways. While, generally speaking, Australians themselves are in favour of the system, there are still some exceptions, who think it would have been better to have kept to private enterprise.

From many years' experience in Australia, and from an intimate acquaintance with the working of the railways in one of the States, and a general knowledge of the others, my opinion is that, taking into consideration that the Governments were the owners of the land principally to be developed and settled, and that the settlement could not be effectually carried out without means of transit, the interest of the public has been best studied and preserved by the State-owned system.

Difficulties and Dangers.

It must not be considered, however, that there are no difficulties or dangers in connection with State-owned railways.

Before the appointment of Railway Commissioners in the different States, the political danger was an apparent one, for even Australian politicians in years gone by were not proof against advocating the construction of certain lines when earnestly pressed by interested constituents, especially where majorities at election times were small; and members for districts in which there were large numbers of railway electors may in some unguarded or over-anxious moments have made promises which to fulfil might not have been beneficial to the State. By placing the construction and control of the railways under Commissioners with extensive powers, these dangers have, to a certain extent, been obviated.

There is also the danger of strikes, and, although not as likely on the Government lines as on private ones, there is no absolute certainty that they might not take place.

Some years ago, in one of the States, the President of the Railway Association, who was not a railway man, but a member of Parliament, lent such encouragement to the men's claims—claims that could not be granted by the Government—that a strike was threatened, and had it not been for the good advice of other members and some of the leading railway officials themselves, trouble might have occurred. Since then, in 1903, as is well known, there was a railway strike in Victoria which was of a somewhat serious character. This strike was brought about by over-zealous leaders of the employees against the advice given them by some of the more responsible and cautious men. The result was most unsatisfactory so far as the men were concerned, for instead of their gaining the sympathy of the public, as they anticipated, the inconvenience and disorganisation caused by the strike turned the sympathy to the Government and against the strikers, and in the end the men found, to their sorrow, that there was no good result to themselves, but for some of them loss and disappointment. Since that time there have been no railway strikes except in connection with the tramways in Sydney, Brisbane, and Perth, and in all cases the result has been unfavourable to the strikers.

A statement that is often made against the Government system is that you do not get the best and most able men, and that employees are not as industrious as on private works. But little reliance can be put on these statements, for it stands to reason that Governments can afford to secure the very best men to manage their works just as well as the private companies can. In fact, many of the Railway Commissioners, as well as the engineers and general traffic managers, have been selected from the leading officials of private companies, and some of the private companies have been glad to avail themselves of the services of men who have gained extra experience in Australia. One prominent case of this kind was the late Mr. Matheson, manager of the Midland Company, and Sir Thomas Tait, late Commissioner of Railways in Victoria, is reported to have been offered a very important position in one of the leading railway companies of Canada.

Travelling accommodation and fares for passengers, and freight rates for goods, compare favourably with the railways even in older and more thickly settled countries. In fact, the freight charges on agricultural, pastoral, and mineral products are in many cases exceptionally low, in order to encourage settlement and development.

A Word in Conclusion.

The Government ownership of railways in Australia is often used as an argument by advocates of a national system in Great Britain. This is a matter, however, that does not come within the scope of this paper further than to add that the conditions of the two countries, and the circumstances under which the railways have been constructed, are so different that the greatest consideration should be given to such an important proposal. The result of nationalisation might be the exact opposite

Hosted by Google

to that expected by some of its warmest advocates.

If the nation as a whole is to benefit, it might mean a great reduction in the number of employees and much inconvenience to traders and residents in certain localities; on the other hand, if the employees and trading public are to benefit by the change, it might result in a heavy national loss.

DISCUSSION.

The Chairman (Lord Emmott), in opening the discussion, said that the paper, so far from being dry and uninteresting, as the author had led them to suppose it might be, had been one of great interest. Particulars had been given of a vast continent with a great undeveloped tract of territory; and to those present who might be anxious about the food supplies of the future it was quite clear that there was ample territory in the continent of Australia to grow a great deal of the food that would be required. He thought the author had made out his case with regard to the indebtedness of Australia, because when it was seen that two-thirds of the total debt was for railways, which were themselves so highly remunerative, then the amount of the debt became of much less importance. He believed he was correct in saying that something like 85 per cent. of the money borrowed by Australia was for purposes which were absolutely necessary and nearly all directly remunerative. With regard to the question of the State construction of railways, he thought any newly-developed country would be very unwise to allow its railways to be built by private enterprise, and Australia had done very wisely in building State railways. The author's figures proved that, over and above working expenses and interest on capital, there was a net profit per annum on the Australian railways of £4,200,000. In the future, when Australia was much more thickly populated than it was at the present time, the benefit would be greater still, because under the conditions of a largely populated country it became much more expensive to buy out the railways, whereas if the State owned them from the beginning it had a much greater advantage. He was sorry there were so many different gauges of railways in Australia, because in spite of the fact that travellers had to change only three times on one particular route in 3,000 miles, it would be very much more satisfactory if they did not have to change at all. He quite understood that when a railway was built through a very sparsely populated country there was a great temptation to build it on a 3 ft. 6 in. gauge, and to construct it as cheaply as possible. He could quite understand the temptation to build the North and South Railway on the narrow gauge from the point of view of expense, but whether that would be a wise thing to do having regard to the future was another question. The author had said a good deal about the Railway Commissioners, and those present knew enough of what local demands were in regard to railway questions to recognise that it was wise that the control of the railways should not be too directly amenable to political considerations. At the end of his paper the author struck a note of warning when he said it was quite possible that the conditions applicable to Australia were very different from those which obtained in this country. Although it was right that Australia should own her railways, it did not follow that it would be a prudent or wise step in this country to buy out the present owners of railways and for the State to work them. That opened up a very large question which was of particular interest at the present time, because probably all present had read the account in the morning papers of an interview with the Prime Minister in regard to that very matter. There were many obvious advantages in the State-ownership of railways, but under present conditions of finance the financial problem would be a very serious one. He did not agree with those who thought that the financial problem was materially affected by the amount of "water" in the railway stock; the real problem was what would have to be paid for the railways. The price of railway stock was comparatively high at the present time, having regard to the dividend that it earned. The question had to be considered whether, after buying the railways, satisfactory savings could be made by eliminating competition, which would make the whole transaction a profitable one. That opened up a very large question, on which most people at present were very imperfectly informed. With reference to the other great difficulty that arose—the question of labour—the vast continent of Australia was good enough to conduct experiments in labour questions which were of very great interest and value to people in the old country. Nevertheless, Australia had had labour difficulties to meet, and might have further difficulties in the future. No doubt labour difficulties could, and in the course of time would, be got rid of, but if that object was to be achieved a basis must be arrived at under which wages could be fixed at a level which was satisfactory both to the employer and to the employed, and so far an ideal system for achieving that result had not been arrived at. At the present time they were very far from arriving at such a stage, and that was one of the difficulties which bulked very largely in many people's minds with regard to the question of whether it would be wise in this country for the State to assume the ownership of the railways. Personally, he did not consider that the difficulty of finding men fit to manage the railways was so serious as some people imagined. On that point he agreed very much with the author. He had had some opportunity of seeing the men in our great Civil Service, many of whom were men of very extraordinary ability. There was no more reason why men of extraordinary business ability should not be obtained, if they were wanted and people could afford to pay for them, than there was why civil servants of extraordinary ability should not be obtained at

Hosted by Google

the present time to do the work they had to do. That difficulty did not bulk largely in his mind, but labour and finance were great difficulties. While he did not think we were likely, in this country at any rate, for the next few years to adopt the principle of State-ownership of railways, at the same time he was satisfied that in a country like Australia they were very wise to do so.

[LORD EMMOTT then vacated the chair in order to keep another engagement, and the chair was taken for the remainder of the meeting by COLONEL SIR THOMAS H. HOLDICH, K.C.M.G., K.C.I.E., C.B., D.Sc.]

MAJOR SIR THOMAS BILBE ROBINSON (Agent-General for Queensland) said that very few people who had not travelled in Australia realised the enormous distances which had to be covered by produce on the way to market, to the coast, or to the stores up country. A lantern slide had been shown comparing the size of Australia and that of Europe. He had surprised many people by telling them what was actually the fact, that the four States comprising British South Africa could be put into the space occupied by Queensland alone, and there would still be 200,000 square miles of territory uncovered. When it was borne in mind that a large proportion of the Australian Continent was still very much in a condition of nature, and that the means of travel where railways did not exist were the bullock waggon and the horse team, it would be appreciated how essential it was that the extension of railways should be proceeded with as fast as possible. It would be readily understood that when the advantages of railways were so great as they were in new countries, a great deal of pressure was brought to bear upon Parliament for further construction before the trade of the districts would, as a commercial undertaking, justify the expenditure. Queensland adopted a method some years ago which had been very effective in checking the demand for what would have been unprofitable railways. Before any new line of railway was made an estimate of the cost and the possible traffic was prepared. That estimate was laid upon the table in Parliament, and automatically, by the operation of an Act which had now been in force for some years, when a railway was made through a district the inhabitants of the district served by the railway were liable to the Government to the extent of 3 per cent. upon the cost of the railway if it should prove unprofitable. It would be very unfair to impose that expenditure upon the taxpayers in the area concerned unless they had the opportunity of saying whether they wished the railway made under those conditions or not. Consequently a local referendum was taken, and if there was a two-thirds majority against the railway the project was vetoed. When the railway had for three years in succession paid 3 per cent. to the Government, the inhabitants in the district were released from their undertaking, because the experience of the Government showed that when a railway had paid for three years in succession a net revenue of 3 per cent. they might with safety take it over and regard it as part of the Government railway, for the successful working of which the Government of the country was responsible. The progress made in the construction of railways was much the same in all the States, but in Queensland, with which he was better acquainted than any of the other States, when the present Commissioner of Railways entered the service of the Railway Department Queensland possessed 21 miles of railway, whereas at the present time it owned over 4,000 miles, and 2,000 further miles were under construction. That expansion, which had occurred within the business experience of one man, showed the extent to which railway development in Australia was being pushed on all sides. A good deal had been said about the question of the difference in gauge. Personally, he did not think that was a matter of so much importance as it might appear to be to one who was not so well acquainted with local circumstances. It was regrettable that there were breaks of gauge between the capitals, but in India there were four different railway gauges, and very little was heard about that. Queensland had adopted the 3 ft. 6 in. gauge, and the railways in that State, although double the length of those in New South Wales, had only cost about half the amount spent by the adjoining State. In a new country, with comparatively few inhabitants, the cost of making the railways, and the necessity for making them as long as possible, went, in his judgment, a long way to justify the selection of the narrower gauge. For all practical purposes the people of Queensland were well content with the 3 ft. 6 in. gauge. It was true the express trains were not run at anything like seventy or eighty miles an hour, but a speed of forty miles an hour could be safely maintained. The practice of the British railways had not been followed of keeping the structure of carriages almost entirely between the two wheels. It had been found from experience that the carriages could overhang on each side, to a certain extent, with perfect safety, and the sleeping carriages now in use on the Queensland railways were, as a matter of fact, three inches wider than the sleeping cars running between London and Edinburgh. The railway stations and tunnels were in some cases wide enough to permit of the laying down of the broader gauge; in fact, the Premier of Queensland, at a recent conference with the Premiers of the other States, offered, so far as Queensland was concerned, to make the New South Wales gauge continuous from Sydney to Brisbane. That would necessitate a third rail being laid from Brisbane to the border, and in order to make the junction with the existing service New South Wales would require to extend her railways by about twenty-eight miles. The project was so near adoption, that he thought within a very short time it would be found that at any rate one of the breaks of gauge as between the capitals had been avoided, and that

Hosted by Google

the New South Wales gauge would be found running right up to Brisbane.

MR. HERBERT W. ELY (Secretary, Tasmanian Government Office) said that Australia possessed the finest climate in the world and resources of the greatest productive possibilities, but those assets would have been useless without a progressive railway policy. The author had pointed out that the Tasmanian railways did not actually pay, but there were sure signs that in the comparatively near future they would do so. The Government had embarked on a progressive construction policy all over the island. Great mineral developments were proceeding on the west coast; mines that had been lying dormant for want of smelters had started, and the smelting works were going full blast; and new mining fields were rapidly being opened up. A new process works was being put up at Rosebery in the centre of the west coast district to deal with the refractory sulphide ores which had been lying untouched to the present day because it had been impossible hitherto successfully to treat them. All that meant that large areas of western Tasmania would be developed, with the result that the whole of the railway system in that part would become a paying proposition, so that the reproach that Tasmanian railways did not pay would be removed in the near future. The author had touched very diplomatically on the question of State-owned railways. He thought everybody was agreed that in a new country like Australia it was impossible for railways to be owned privately without a large concession being granted, and without sooner or later coming into conflict with the developmental policy of the Government of the country. For that reason it was most advisable, where the main railway system existed, that the whole of the railway system should be in the hands of one authority. Another point was that only a Government could afford to build a railway and to run the risk of it being run for the first few years at a loss. That had frequently happened, because the railways must be pushed forward into new country in order that settlers might follow the railway and develop the land. It was quite impossible to expect a settlement in a new country where the people had to send their produce perhaps hundreds of miles by road, not to speak of the appalling isolation with which they were confronted; so that unless a private company had some recompense in a large land concession, the work must be undertaken by the Government.

MR. H. S. GULLETT thought the most attractive part of the paper was where the author made the statement that railways were now being built in Australia at a rate considerably faster than had been known in the past. The rate at which Australia was building railways had a very important bearing upon the immigration question, and the present railway policy was one of the best assurances that could be given to the British people that Australia was taking all possible steps to make room for large numbers of British emigrants. The immigration figures in recent years had been very remarkable. In the ten years between 1895 and 1905 Australia made a net gain by immigration of only about 500 people a year. Between 1905 and 1908 the rate of gain was increased to some 17,000 a year; in 1909 there was a gain of 29,000; in 1910, 37,000; and last year between 70,000 and 80,000. Most of the people were adults who were going on the land. If the wonderful example of Canada was followed, it might safely be predicted that in five or six years' time about a quarter of a million people a year would be taken into Australia, if sufficient boats could be obtained to carry them. The new railways were of great importance, because they increased the settlement upon the farming country, and they were also making much safer the pastoral settlement. Large sums of British money were invested in Australia in pastoral production, and in the low rainfall districts the trouble in dry seasons was chiefly due to the fact that the stock could not be moved about as readily as was desirable. Australia very rarely had a general dry season, and if it was able by means of railway systems to transport the stock quickly from one portion of the country to another, they practically insured the whole of the pastoral country against trouble in time of drought. That he thought was one of the most important features, from a national standpoint, of railway construction in Australia at the present time. By means of the new big transcontinental line, Australia was linking up the east, where most of the people were to-day, with the lightly populated west and north, and so bringing Australia closer to Europe. It was very interesting at a time when the building of a railway was being considered right down through Europe and Asia to Bombay, that the question of the construction of the transcontinental line across Australia was under consideration. If the trans-Asia railway were constructed London would be only seven or eight days from Bombay; Bombay was within nine days' steaming of Australia—and that time could be very much shortened—so that it was quite possible that in twenty years' time England would be within fourteen or fifteen days of the eastern States of the Australian Commonwealth.

MR. H. C. ALLEN (Buenos Ayres Great Southern Railway Company) said that railway men in the Argentine Republic naturally took a very great interest in railways in all parts of the world. Of the 20,000 miles of railways in the Argentine Republic, 80 per cent. were owned and worked by private English companies. The Government, however, owned some of the railways, which they had constructed, he thought, in very suitable parts of the country, inasmuch as the districts through which they ran were difficult to develop by means of private enterprise, because the railways were not likely to pay for a long time. Three different gauges of railway existed—the Indian gauge of

Hosted by Google

5 ft. 6 in., which was the original gauge in Argentina; the 4 ft. 8½ in.; and the narrow metre gauge. He could bear out the remarks a previous speaker had made with regard to the advantages of narrow-gauge railways in certain parts of the world, more particularly where the first cost was a question of great importance. The overhang indulged in by the railways in Argentina had enabled many of the narrow-gauge lines to have almost as wide carriages and waggons as some of the 5 ft. 6 in. lines, because the width of the rolling-stock of the latter was regulated by the existing stations, bridges, etc. To increase the overhang of the carriages and waggons under such conditions, in order to get the full benefits that the width of the gauge might give, would be an exceedingly expensive matter. It was a common thing on a metre-gauge line to have 30-ton waggons and luxurious sleeping and dining-cars and other conveniences similar to those provided on the 4 ft. 8½ in. railways at home.

Mr. W. P. Durtnall, speaking as an engineer, thought it was extremely desirable that the possibilities of the internal-combustion engine for use on Colonial railways should be thoroughly investigated before an enormous expenditure was incurred in the provision of steam-operated trains. There was also the possibility of the combination of high speed internal-combustion engines with electrical apparatus, a self-contained locomotive thus being obtained. It had been proved, he understood, that for 1 ton of oil costing 40*s*., a train of 300 tons could be driven four or five times farther at the same price than a train drawn by a steam engine.

The Chairman (Colonel Sir Thomas H. Holdich) said that unfortunately his travels had never taken him to Australia, and he was, therefore, entirely ignorant of the country, and his public services had never in any way been connected with railways. But as he had lived for many years in India he wished to draw attention to the fact that it was always exceedingly dangerous to accept the analogy of one country in matters of railway construction or railway policy as a guide for another. He regarded Australia as a trebly blessed country. It had no North-Western Frontier with a perpetual recurrence of North-West Frontier wars; famine was practically unknown in the country; and there was nothing in the shape of a deadly pestilence to contend with; all of which were well known to the Government of India, and had interfered from time to time with the development of railways under State control that would have taken place had Government been free from those troubles and difficulties. It was the fact that Australia, with its comparatively small population of four millions, had rather more than half the length of railways which India possessed with a population of something like 300 millions; and yet it would be very difficult to say that railway construction in India could be pushed ahead, either under State control or by private enterprise, to any very considerable extent faster than it was now. Although he thought State regulations with regard to construction might very well be modified so as to make it easier for private enterprise to undertake a greater extension of railways than was the case at present, nevertheless in a country like India, where financial support was dependent on such causes as he had just mentioned, it was impossible to expect any very large and decided increase to the great system of railways in that peninsula such as might be expected in such countries as Australia or Tasmania.

The Hon. J. G. Jenkins, in reply, said the remarks made by the various speakers had been so complimentary that there was hardly anything to reply to. With reference to Mr. Durtnall's remarks, he noticed from a cablegram received about a week ago that the Minister for Home Affairs of the Commonwealth Government, who was specially interested in the construction of the proposed railways, had stated he was making every investigation into the possibility of utilising petrol-power instead of ordinary steam-power, so as to save the expenditure of, he believed, nearly half a million pounds in the construction of waterworks along one of the routes. That statement was probably authentic, but whether the report meant that the Commonwealth Government were going to adopt the system he could not say. He knew, however, that the Government would not be blind to the possibility of saving money by adopting any new system, if it was practicable for the purpose.

On the motion of Mr. Byron Brenan, C.M.G., seconded by Mr. Harry E. Brittain, a hearty vote of thanks was accorded to the author for his interesting paper, and the meeting terminated.

THE PHOSPHATE INDUSTRY IN ALGERIA.

The most important deposits of mineral phosphates in Algeria are to be found in the Department of Constantine, and more particularly in the neighbourhood of Tebessa, close to the Tunisean border. Amongst the principal beds of phosphate of lime, those at Ain-Kissa and Dibba, situated about five miles from Tebessa, worked by a French company, are of considerable importance. Another company operating near the village of Bordj-R'dir have an output of about 20,000 tons annually, which, by means of an aerial cable 10½ miles in length, is carried to the railway station at El-Anaced, and from thence to the port of Bougie for shipment. There are also important beds of this substance at Dyra-Nord, about thirteen miles to the north-west of Tebessa, yielding 65 to 70 per cent. of phosphates.

Amongst the most important deposits of phosphates in the colony may be mentioned those at Djebel-Kouif situated to the north-east of Tebessa, which are exploited by an English company. The substance when first excavated is grey in colour,

Hosted by Google

which rapidly turns white when exposed to the air; it yields 58 to 60 per cent. of phosphate. The mines are connected with the railway to Bona, where it is shipped.

The deposits at Tocqueville, worked by an Algerian company in the western part of the Department, are situated about twenty-four miles from the station at Setif on the railway from Algers to Constantine, to which they are connected at Tixter by a narrow-gauge line about eight miles in length. The mineral, which contains 58 to 60 per cent. of phosphates, is shipped at Bougie.

The exports of the natural phosphate of lime from Algeria have increased nearly three-fold during the last ten years, as will be seen as follows:—

	Exports.		Total Exports.	
	To France. Metric tons.	To other Countries. Metric tons.	Metric tons.	English tons.
1902	46,815	81,581	128,396	126,374
1903	72,049	276,027	348,076	342,594
1904	87,524	279,810	367,334	361,549

ARTS AND CRAFTS.

Home Arts and Industries.—The Twenty-eighth Annual Exhibition of the Home Arts and Industries Association, which was held at the Albert Hall in the middle of May, was a more than usually interesting event. The Association has done yeoman service for many years in helping forward the movement for the revival of artistic handicrafts, and its shows have always been well worth a visit; the time has now come when they represent not only aspirations but also a good deal of real accomplishment. Some of the Developed Industries, it is true, seem to the outside observer to have passed the stage when their connection with the Association is altogether incomprehensible; but leaving these exhibits out of account, the work turned out by the Partially Developed Industries and the Home Art Classes, is not only creditable to those concerned in its production, but interesting and attractive in itself, quite apart from sentimental considerations as to how and by whom it was carried out. Very little of the rather showy work, grand enough in conception but lamentably poor in execution, which seemed to threaten to predominate a few years ago, was to be seen this year. Some work there was, indeed, large in scale and ambitious in aim, but in most cases the ambition was justified by the power to carry it through successfully; moreover, the number of exhibits of this type was not very considerable. The bulk of the exhibition was made up of modest and tasteful work, quite pleasing in design, and executed with a very reasonable amount of technical skill. The objects on view did not call aloud for notice, but when they were carefully looked at they were generally very satisfactory both in design and workmanship, and would have more than held their own had they been shown with works produced under different conditions. When one remembers the kind of exhibits which were in the majority at the exhibitions held some ten or fifteen years ago, to go no further back, one realises how much the Association has done to foster and direct home industries in this country. People are ready enough when they travel on the Continent to grow enthusiastic over, and to patronise, the peasant industries which they find there—is that, perhaps, in part due to the fact that their products can be purchased so very cheaply?—but they are apt to forget that even in England we have peasant industries which are by no means to be ignored.

Since a great many of the workers connected with the Home Arts and Industries Association are women, it is only natural that embroidery, lace-making, and weaving should be amongst the crafts most largely represented at the Albert Hall. Some of the drawn-thread work, notably that from Langdale, was very good, and the workers are beginning to appreciate the value of colour introduced in work of this kind. The samplers from Milford were on the whole very dainty, and extraordinarily satisfactory in colour, whilst the embroidery and weaving from Windermere was, as one has grown to expect, characterised by a strong appreciation of the value of colour. The lace from East Devon was, much of it, remarkably accomplished work, and there was good work sent from Diss, Buckinghamshire, and other places. Rugs have come to be quite an important class of exhibits, and many of them were very good in colour. Some of the lacquered leather was rather aggressive, but the leatherwork shown by Leighton Buzzard, and the work of other, less advanced, classes, was generally well executed and pleasing in tone. The carving as a whole was a good deal better than usual. The exhibits from Ascott were really remarkably satisfactory, and many of the less ambitious classes sent very good examples of chip carving, and simple work in low relief. The metal-work from Yattendon was well-made and attractive, and the pottery from Compton was not wanting in the peculiar charm which one associates with it.

The Book Exhibition at the Central School of Arts and Crafts.—The exhibition of the work done in the London County Council trade-schools connected with book production, which was held at the Central School of Arts and Crafts during the latter part of May, showed very clearly how much is being done for the artistic and technical training of bookbinders and printers. The account of the history of the Council's classes in book production, published in the catalogue, shows, amongst other things, how a scheme of training in printing and bookbinding has been established, which ought to help boys to a better practical and theoretical knowledge of their trade, without unduly delaying their apprenticeship. The trouble with the technical schools in the past has been that boys trained

Hosted by Google

in them naturally do not want at the end of their school days to start in their trades on the same level as boys who have just left an ordinary elementary school, whilst the masters are a little afraid of employing them on any other footing than that of beginners. The plan of allowing boys to enter the trade-school at thirteen years of age, and of apprenticing them while they are still there, seems to point the way to a solution of the difficulty. The specimens of typesetting—titlepages, notices and displayed work generally, as well as simpler work—made it very evident that the students in this department of work are being trained to produce tasteful pages, far better spaced and arranged than the ordinary run of trade productions. Some of the examples shown were really excellent, and the work as a whole was on good lines and tending altogether in the right direction. It makes one hope that in the near future, not only bookwork but advertisements may be more artistically planned than is at present the case, although they are already far better than they were some years ago. The writing and illuminating shown was good and rather more catholic than usual, one or two specimens being written in a quite pretty and comparatively modern type of hand; but in spite of the fact, called attention to in the catalogue, of a German fount of type having been inspired by the English revival in pen-made lettering, a good deal of the work done in this section, beautiful as it is, seems somewhat remote from practical present-day needs. The bookbinding, again, does not give one any idea of the possibility of a tasteful book-cover which is within the purchasing power of any but the rich. This is, doubtless, as it should be from one point of view, since our ordinary cloth-cased books are not bound at all in the stricter sense of the word—but one looks in vain for any designs for cloth casings or suggestions as to their colouring. There were a large number of leather-covered books on view, and they were well bound and very often tastefully ornamented. A certain tendency to over-enrichment was probably due to the students' desire to do all they knew and to do as much tooling as possible on one volume. The work as a whole reached a very high level, and gave evidence not only of good workmanship, but in some cases of a real power of planning and designing simple and effective tooled covers.

Two Bond Street Exhibitions.—Two exhibitions have been held in Bond Street during the past month which are worth recording from the point of view of Arts and Crafts. At the Doré Gallery, Baron Arild Rosenkranz has been showing a large four-light memorial window, together with a smaller window and a little panel of stained glass. The memorial window consists of four full-length figures (labelled—not in pre-eminently satisfactory letters—as Fortitude, Faith, Truth and Justice) very skilfully framed by a vine with a thick purple-brown stem and clusters of white fruit. The general effect of the figures is blue-green and the flesh is decidedly greenish in tone, but a certain amount of purple is introduced in the draperies in such a way as to keep the general colour-effect from being in any way sickly—while the pearly, almost semi-opaque, glass of which the background is composed, fits in peculiarly well with the general colour-scheme and gives a certain homogeneousness to the window, which would have been lacking had the ground been leaded up in clear glass or been formed of painted quarries. Baron Rosenkranz evidently understands very well the importance of using good glass in his windows. It looks as though, in this instance at any rate, he had chosen every piece to fit its own particular place in his composition, and the result has amply rewarded his pains. The colour of the small baptistery window is not so satisfactory, but that may be due in part to the conditions under which it is shown; and the artist certainly proves in his small panel of bright red birds flying amidst vivid green leafage that he can manage strong pot-metal colours very successfully. The little exhibition was a striking proof of the importance of the artist keeping in touch with his window after it has passed the cartoon stage. In dealing with stained glass it is not enough to indicate that a certain piece of drapery is to be green, or even of a particular shade of green, if one wishes to get the best effect out of a material which displays the infinite variety to be found in a single piece of pot-metal glass. What is necessary is that the artist shall personally supervise the window and have something to do with the choice of the glass actually employed.

At the St. George's Gallery, the Misses Violet and Frances Ramsay have been showing some jewellery which is quite worthy of their reputation. Among the many women jewellers of the present day, there are perhaps some who turn out daintier and more lightly pretty work, but there are none who have more feeling for style or a better sense of proportion, and of how to introduce their stones in the most satisfactory way. Miss Dora-Brooke Clarke's work, which was shown at the same time, though by no means poor, was not able to hold its own in the company in which it found itself.

CORRESPONDENCE.

THE ETYMOLOGY OF NAILBURN.

The discussion raised by the Rev. W. Blissard, of Bishopsbourne Rectory, Canterbury, on the etymology of the term nailburn, as applied to the intermittently flowing brooks of Kent, is of wide interest, and should find a record in our *Journal*. He himself, writing in the *Times* of the 13th May, suggested that the word was a corruption of "helburn," or "elburn," meaning a "heled," that is, a concealed burn or brook: as in the case of Helwell, meaning "the Covered well," in

Hosted by Google

Devonshire. In the *Times* of the 15th May, Professor Skeat,—an authentic miracle of philological science, and etymological scholarship, and the pure shining light of contemporary English lexicography,—quoting from Birch's "Anglo-Saxon Charters" the forms "Naeglesburnan," which he renders Nailsburn, and "Nælesbroc" as Nailsbrook, and "Neglescumb" as Nailscombe, and "Nægleslеah" as Nailsley, observes that it would appear as if Naegel [Nail] could be used as a personal name; and immediately continues: "There is an interesting article on Nagel in Schmeller's 'Bavarian Dictionary,' in which he reminds us that it was the name of the peg used in the peg-tankard, and was even used to express a definite quantity of liquor [compare 'brandy pegs' of Anglo-Indians] . . . I am unable to say if there ever was a hobgoblin called Nael . . . but I think I have proved clearly enough that the English word ought to begin with [a capital] N." Beyond that Professor Skeat does not dare.

Only Ulysses may bend Ulysses' bow; but, failing some "goblin dam'd," or "Saint" Nigel [= "Nigger"], I must "make bold to say"—as people say in Devonshire—that I still hold by the Rev. W. Blissard's solution of the problem, although for other reasons than those advanced by him. It is quite true that in Devonshire "to hele" everywhere means "to roof" a house, and, in particular, with "heling stones" or slates; and also to tump-tump potatoes, celery, etc.; and throughout "Wessex" "hellier" means a slater, a tiler, and a thatcher [whence such surnames as Hillier, Hellyar, Tyler, Tylor, Thuillier, etc.]; while "hele," in the form of "eel," means, all along the March of Wales, "to cover" generally. But there is another "hele," or "hell," in provincial English, meaning, in Wiltshire, "to pour out," and in Yorkshire, in the form of "hellered," "a river in flood"; and elsewhere, in the form of "hellek," any "small stream." Accepting, therefore, in default of an eponymous hobgoblin, or saint, the possibility of nailburn being a corruption of "helburn" or "elburn," I would argue that the "hel," or "el," in the term has nothing to do with the periodic calypsis of the "nailburns" of Kent, and that these alternative flections simply mean "burn," or "brook"—in the present instance the burn or brook that gives its name to Elham; and that nailburn here, and elsewhere in Kent, is but a repetitive denomination, meaning "brook-brook," examples of which we have in such tautological place-names as Elbe-river, Wash-burn, Ouse-burn, and Ash-bourne, all meaning "Water-water"; and again, in Romney-marsh, meaning "Marsh-marsh," and in Brai-don-hill, meaning "Hill-hill-hill."

Nail from *nægel*, "a nail," "a pin," "a peg," is to be found in English place-names, and in respect to them is generally referred, I cannot say traced, although I would fain have it so, to "Saint" Nigel. In the Norse form of *naal*, it is found in the name of Nalsöe, one of the Far öes, or "Sheep-islands." The Devonshire "neele" for needle, is the Dutch *naael*. The English surnames Nail, Naile, Nall, refer to ancestral residence "at *an-ale* house"; and of Nailer, Nailor, Nayler, to ancestral occupation of nailers; at least, so the etymologies of these patronyms have been—so far!—"dared, determined, done," by the masters of such familiar mysteries.

If all this still leaves the problem of nailburn unsolved, my reply is, that the liveliest interest in every research lies in its pursuit, and not in its solution. The eccalypsis of our earthly, palaeocrystic Poles, has made the Southern Pole, with its delightful, companionable penguins, as homely as Clapham Common; and the Northern, as familiar as our "Happy" Hampstead Heath of Sundays.

George Birdwood.

INDIAN RAILWAYS.

As Mr. Neville Priestley has completely misunderstood at least one—the first—of my reasons for believing that the 1910 Rebate Terms will prove as unsuccessful as those of 1893 and 1896, I shall be obliged if you will find room for this letter in the next issue of the Society's *Journal*. I will deal with Mr. Priestley's remarks seriatim—

(1) I am quite aware that the Rebate Terms specifically limit the cost of working branch lines to 50 per cent. of the branch line's gross earnings. This proviso is not new, and will be found in the Rebate Terms of 1893 and 1896 as well as in those of 1910. But this has nothing to do with the point raised by me. My reference was to the cost of working traffic *interchanged between the branch and main lines*, not to the cost of working branch-line traffic. The cost of working the first-named traffic has not, so far as I know, been definitely fixed, and by implication the 1910 Rebate Terms show this. If the cost of working this traffic had been definitely fixed at 50 per cent. of the gross earnings, Government would surely have adhered to the principle of the previous Rebate Terms, and have offered a rebate "not exceeding 50 per cent. of the *gross* earnings," and not one "not exceeding the *net* earnings." The presumption is that Government themselves recognise that the *net* earnings may possibly be *less* than 50 per cent. of the gross earnings. In my opinion they will be found to be considerably less.

(2) I never stated that the main lines are not interested in "working up" the traffic of branch lines. Obviously they are interested. What I said was, that where the rebate would be *most* wanted, the main line had no direct interest in keeping the cost of working the interchanged traffic low. In such cases, where the whole of the net earnings of this traffic are absorbed by the branch lines, that is, where the interest of the branch lines calls for low working expenses, the main line has no direct interest whatever in keeping them low. As this traffic then contributes nothing to the main-line revenue, why should that line go out of its way to

Hosted by Google

reduce expenses? That the Rebate Terms provide for Government taking over branch lines *before* the expiry of the contract, confirms my statement that the position of branch lines is in many ways unsatisfactory, and that they have no future.

(3) With all respect, I cannot accept as an axiom Mr. Priestley's dictum that it must be assumed that the financial advisers to Government, in all cases, know their own business best, or that they have always good and sufficient reasons for their action. But in the present instance, I am quite prepared to admit that their advice is good, and that Government is wise in following it. It is because I consider that advice good, because I think that Government are wise in not taking upon themselves the risk of constructing branch lines on Rebate Terms, that I believe that investors will be chary in accepting them. J. FORREST BRUNTON.

Mr. Neville Priestley, to whom the foregoing letter has been submitted, writes:—

I am sorry I misunderstood what Mr. Forrest Brunton said, but the reasons he now gives for his views do not, in my opinion, alter the situation in any way. Taking his points seriatim—

(1) He is quite right when he says the Rebate Terms do not limit the cost of working interchanged traffic to 50 per cent. thereof; but they do limit it to the same proportion as the working expenses of the main-line system bear to its gross earnings. That, it is true, is an indefinite figure, but by looking at the past history of the main line it is possible to form some idea of what the cost of working interchanged traffic is likely to be, and consequently what percentage the net earnings are likely to be of the gross earnings from interchanged traffic. Having ascertained this, however, one is no nearer an exact figure, as the amount of the interchanged traffic itself is an unknown quantity and it would not carry one any further in one's knowledge if Government were to lay down that the net earnings from interchanged traffic were to be taken at 50 per cent. of the gross earnings therefrom. Nor could the position be otherwise, because if the amount of rebate could be fixed, it would virtually become a guarantee. A direct guarantee only operates when the income of the line itself fails to cover its interest charges, and that would be the case with the rebate also. It is the indefiniteness of the amount of the rebate that gives the stock its speculative character, and takes it out of the category of guaranteed stock in which trustees may invest and places it in the category of unguaranteed or "ordinary" stock in which trustees may not invest and from which a higher return is, therefore, demanded. Whereas, if the amount of the rebate was fixed, it would become guaranteed stock, and lines promoted under the Terms would fall immediately under the hampering influences of such stock.

(2) The main line cannot control the *cost of working* interchanged traffic, that is to say, make it greater or less because the traffic was important or otherwise, for the simple reason that interchanged traffic is not confined to a particular section of the main line or carried separately from other traffic. But even if the main line could control the cost of working interchanged traffic, it would make no difference, because the cost of working such traffic, so far as it affects rebate, is based on the cost of working the entire system. I cannot see how the fact that the Rebate Terms allow of the acquisition of lines constructed under them before the expiry of the contract is injurious. Stockholders are interested in dividends and in securing their capital. Government undertake to pay back not twenty times, which is what the price at which their stock stands would require, but at twenty-five times the average net earnings. That not only gives the investor all his money back, but a considerable bonus as well. The terms are, therefore, generous and statesmanlike, not mean and pettifogging.

(3) I speak with an inside knowledge of the Government of India, an advantage which I think Mr. Brunton has not had, and I can say very positively that when determining the borrowings for the year, the thought never enters into the minds of the Secretary of State's financial advisers whether a particular line will or will not cover interest charges. Indeed, it is not till after the amount to be borrowed has been decided that the lines which are to be constructed are selected, and the selection—I speak again with inside knowledge—is not influenced by the returns likely to be yielded, but is governed by the importance of the line from a famine or strategical point of view or, when these considerations are not uppermost, by the seductive advocacy of some Governor or other important personage or public body. For the Government deliberately to foist upon a confiding public a scheme which they know to be unsound, would not be clever but excessively stupid, because it would defeat their own object, which is to try to coax private enterprise to undertake the construction of railways in India. I do not think one need go further back than the last loan to realise the difficulties of the India Office in regard to the raising of money. It is to meet that difficulty that the Rebate Terms of 1910 were promulgated, and it was to show what influences are still likely to operate against the attainment of their object by the Government that my paper was written.

NOTES ON BOOKS.

MEN AND MEASURES. By Surgeon Lieut.-Colonel Edward Nicholson, F.I.C., F.C.S. London: Smith, Elder & Co. 7*s.* 6*d.* net.

As the sub-title indicates, this volume is "a history of weights and measures, ancient and modern," an extraordinarily difficult and complicated subject, which the author has spent many years in studying. The importance of securing standard weights and measures is so obvious that

Hosted by Google

they may be said to be among the first essentials of civilisation, and no one will be surprised to learn that among the earliest peoples of whom we have any record there were elaborate systems. But one may, perhaps, be surprised to hear on what scientific bases some of these systems were built. "There is not the slightest doubt," says Colonel Nicholson, "that the common cubit of ancient Egypt, brought probably from Chaldaea, was deduced from the measurement of the earth, from the quarter-meridian distance between the pole and the equator. There are no written records of this measurement; but an imperishable monument remained to record it, and other ancient monuments still remain to corroborate this testimony. The base of the Great Pyramid was, from ancient times, always known to be 500 cubits long on each side, and it is found to be exactly half a meridian mile, or 500 Egyptian fathoms, in perimeter. There is no doubt that the wise men of the ancient Eastern kingdoms had great astronomical knowledge, and were capable of making the necessary meridian measurement."

It is not possible, of course, to follow Colonel Nicholson in detail through his history, either of the early scientific systems of weights and measures or of the genesis of what one may call the rule-of-thumb systems, which were based on such measures as the digit, palm, span, etc. Suffice it to say that he gives a careful account of a large number of systems, ancient and modern, occidental and oriental, some of which afford very interesting reading. The variety of systems which have been in use in different parts of this country is extraordinary, and makes one wonder how, with all this complication and confusion, it has been possible to carry on business at all. But in spite of one's preconceived theories, it seems possible that the rough-and-ready systems, which have grown up apparently by chance, may possess practical advantages outweighing the theoretical benefits of a scientifically planned table.

In this connection, Colonel Nicholson's chapter on "How the Metric System works in France"—one of the most interesting chapters in the book—is particularly instructive. He quotes a great many instances to show how, in spite of official pressure, State education, and police proceedings directed to enforce the adoption of the scientific methods, the old-fashioned systems still persist. "Barometers for ship-use have their scales usually in ponces and lignes. The port barometer on the quay of the great naval port of Toulon, in front of the town hall, is on this old scale . . . The sounding-line of French ships is in brasses of five old French feet, the cable is of 120 brasses, the knot is, as with us, $\frac{1}{120}$ of the nautical mile of 1,852 metres, the kilometre being absolutely ignored. . . . Wine is sold wholesale by the queue, by the barrique, by the feuillette. A barrique or piece of Bordeaux wine is 228 litres; of Burgundy 212 litres. . . . The housewife continues to ask for a four-pound loaf, a *pain de quatre livres*, for a *livre* of sugar, for a *demi-livre* of coffee, for *un quart* of chicory, for a *demi-quart*, or for *une once* of pepper. In the market-place, in the streets, fruit is openly cried at *quatre sous la livre!* or *deux sous le quart!* when no policeman is within hearing, and the police are discreetly deaf, even in Paris, except when ordered to be more vigilant . . . In country towns goods are often openly ticketed in sous; I have even seen 'six liards,' six half-farthings, two for three-halfpence, as the marked price . . . The peasant bargains for cattle in écus (half-crowns), or in pistoles of ten francs . . . Land is reckoned in the old measures according to local custom, and tables of these measures, with their metric equivalents, are given in the 'Usages locaux,' published for the use of *juges de paix* and other officials. Farms to let and land for sale are frequently advertised in these local measures. If the extent is given in hectares, the local equivalent in vergées, etorées, etc., is added . . . I ask a farmer, not six miles from Paris, how much land he has, and he, knowing me to be 'safe,' says so many estrées. How much is an estrée? Sixteen hundred square toises is his answer."

Colonel Nicholson multiplies these instances through several pages, but perhaps enough have been quoted to show how exceedingly difficult it is to change the weights and measures of a people, even when you substitute for clumsy and unmanageable tables the most simple systems designed by the greatest of mathematicians, and backed by all the authority of the State.

ARTISTIC LEATHER WORK. By E. Ellin Carter. London: E. & F. N. Spon. 2*s*. 6*d*. net.

Miss Ellin Carter is well known as a specialist in the artistic decoration of leather, particularly in the Mexican style; and, in addition to being a craftswoman herself, she has had considerable experience as a teacher. Consequently she is in a position to know both what the young student wants in a text-book, and to supply it. This little volume is simple and practical. After describing the tools and materials, Miss Carter discusses the different methods of decorating leather, by incising, embossing, modelling, carving, hammering, etc.; and this she follows with useful sections on colouring and staining, padding and making up. Hitherto there does not appear to have been a good elementary manual designed for the use of beginners, and Miss Carter's book should prove useful in encouraging young students to undertake the study of a charming and artistic craft.

GENERAL NOTES.

THE CRICKET-BAT WILLOW.—The Kew *Bulletin* contains an interesting note on the cricket-bat willow. The best of all willows for bat-making is a pyramidal-growing female form of the blue willow (*salix alba* var. *coerulea*) which, except for recent plantings, is only found in a few East Anglian counties. The East Anglian climate is

Hosted by Google

the driest and sunniest in the United Kingdom, and doubts existed whether the timber of the cricket-bat willow would retain its peculiar value if it were produced in a warm, humid climate. Large numbers of cricket-bat willows have been planted during the past five years, and it has become important to ascertain how far the labour and expense incurred in districts with such a climate is likely to be recompensed. An encouraging report is made on some timber of cricket-bat willow grown on the estate of Mr. J. Arthur Campbell, at Arduaine, Lochgilphead, Argyllshire, where the rainfall is 60 inches per annum, as compared with that of East Anglia, which is under 25 inches. There appears to be sufficient proof that the peculiar virtues of the willow are inherent and not necessarily dependent on its environment.

Cedar Rails for Pencil Wood.—The demand for cedar-wood for pencils has been so great of late that every possible source of supply has been eagerly sought for. It seems that the early settlers in Tennessee built their houses of cedar logs, which have stood exposure to the elements without suffering much damage. A considerable number of these buildings have been stripped of their cedar, and large quantities of the wood have been shipped to Germany and other countries. A substantial source of supply has also been found in the old fence-rails of cedar which are plentiful in Tennessee. These rails, according to *Timber News*, are a source of great wealth to many farmers; in one case it is stated that they were even of greater value than the farm itself. During the past year, in the Murfreesboro' section alone of the State, the American Pencil Company paid $200,000 for old cedar rails, to be used in the manufacture of pencils.

Servian Textile Industries.—Carpet-weaving is one of the oldest industries in Servia. The product is manufactured principally at Pirot, in south-eastern Servia, and the carpets are named after that place. A large number of women and girls are engaged in this industry, and practically every home in the Pirot district has at least one carpet-loom. The chief characteristics of these carpets are that they are made of pure wool dyed with natural colours by local dyers, who pride themselves that the process of dyeing and colour-mixing is a secret transmitted by father to son, and is known only to the inhabitants of Pirot. The manufacture of articles from hemp and flax is an important home industry. The climatic conditions of southern Servia are so exceptionally favourable for growing hemp and flax that practically the whole village population in that region is engaged in the culture of these two plants, and the industry is of the greatest importance to the welfare of a large number of people. The industry is beginning to pass into the hands of larger manufacturers, and modern factories, producing cordage, etc., have been started in several places.

MEETINGS FOR THE ENSUING WEEK.

Monday, June 10...Geographical, Burlington-gardens, W., 8.30 p.m. Sir William Willcocks, "The Garden of Eden."

Tuesday, June 11...Photographic, 35, Russell-square, W.C., 8 p.m. Mr. F. Martin Duncan, "The Application of Photography to Biological Research."

Colonial, Whitehall Rooms, Whitehall-place, S.W., 8.30 p.m. Dr. Vaughan Cornish, "The Panama Canal and its Relation to the British Empire."

Gas Engineers, at the Royal United Service Institution, Whitehall, S.W., 10.30 a.m. Annual Meeting. 1. Mr. R. G. Shadbolt, Presidential Address. 2. Report of the Refractory Material Research Committee. 3. Report on the Education and Certification of Gas Fitters. 4. Mr. H. Townsend, "The Incidence of the Day Load Factor." 5. Mr. A. W. Onslow, "High-Pressure Gas for Manufacturing Purposes."

Wednesday, June 12...American Women in London, Society of, at the Royal Society of Arts, John-street, Adelphi, W.C., 3 p.m. Mr. de Lisle Burns, "Bergson's Philosophy."

Biblical Archæology, 37, Great Russell-street, W.C., 4.30 p.m.

East India Association, Westminster Palace Hotel, Victoria-street, S.W., 4.30 p.m. Mr. William Durran, "The Defects in the Legal Systems of England, India, and America."

Aeronautical, at the Royal United Service Institution, Whitehall, S.W., 8 p.m. Mr. G. Holt Thomas, "Hydro-Aeroplanes."

Royal Society of Literature, 20, Hanover-square, W., 5.15 p.m. Professor M. A. Gerothwohl, "Alfred de Vigny, and his Relation to English Pessimists."

Gas Engineers, at the Royal United Service Institution, Whitehall, S.W., 10.30 a.m. Annual Meeting. 1. Mr. S. Meunier, "The Evolution of Stockport Gas Works." 2. Dr. R. Lessing, "A Laboratory Method for the Comparison of the Coking Properties of Coal."

Thursday, June 13—Antiquaries, Burlington House, W., 8.30 p.m.

Mathematical, 22, Albemarle-street, W., 5.30 p.m.

Gas Engineers, at the Royal United Service Institution, Whitehall, S.W., 10.30 a.m. Annual Meeting. 1. Mr. T. Glover, "Some Observations on the Examinations in Gas Engineering." 2. Mr. J. H. Brearley, "Some Notes on the Examinations in Gas Supply."

Friday, June 14...Royal Institution, Albemarle-street, W., 9 p.m. Mr. A. H. Savage Landor, "Unknown Parts of South America."

Malacological, Burlington House, W., 8 p.m. 1. M. M. Schepman, "On a Collection of Molluscs collected by Mr. E. Jacobson in Java." 2. Dr. J. Cosmo Melvill, "Descriptions of Thirty-three New Species of Gastropoda from the Persian Gulf, Gulf of Oman, and Arabian Sea." 3. Mr. Wm. H. Dall "Note on the Generic Name *Pectunculus*. 4. Mr. Tom Iredale, "Note on *Ianthina* Species.' 5. Mr. Maxwell Smith, "Egyptian Non-Marine Molluscs."

Astronomical, Burlington House, W., 5 p.m.

Geologists' Association, University College, W.C., 8 p.m. Professor Grenville A. J. Cole, "The Geology of West Mayo and Sligo, with special reference to the August Long Excursion."

Physical, Imperial College of Science, South Kensington, S.W., 8 p.m.

Municipal and County Engineers, Town Hall, East Ham, E., 11 a.m. Mr. J. E. W. Birch, "The Public Works of East Ham."

Hosted by Google

Journal of the Royal Society of Arts.

No. 3,108. VOL. LX.

FRIDAY, JUNE 14, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

NOTICES.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Fifty-Eighth Annual General Meeting, for the purpose of receiving the Council's report and the Treasurers' Statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new members, will be held, in accordance with the By-laws, on Wednesday, June 26th, at 4 p.m.

(By order of the Council),

HENRY TRUEMAN WOOD, *Secretary.*

MEDALS FOR PAPERS.

The Council have awarded the Society's Silver Medal to the following readers of papers during the Session 1911–12.

At the Ordinary Meetings :—

ALGERNON E. BERRIMAN, "The Efficiency of the Aeroplane."

PROFESSOR G. W. OSBORN HOWE, M.Sc., M.I.E.E., "Recent Progress in Radio-Telegraphy."

CECIL THOMAS, "Gem Engraving."

H. A. ROBERTS, M.A., "Education in Science as a Preparation for Industrial Work."

F. MARTIN DUNCAN, "The Marine Biological Association, and some account of the Work it has accomplished."

THEODORE E. SALVESEN, "The Whaling Industry of To-day."

GEORGE FLETCHER, "Technical Education in Ireland."

E. D. MOREL, "British Rule in Nigeria."

ERNEST KILBURN SCOTT, Assoc.M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere."

In the Indian Section :—

J. TRAVIS JENKINS, D.Sc., Ph.D., Superintendent of Lancashire and Western Sea Fisheries, "Fisheries of Bengal."

E. A. GAIT, I.C.S., C.I.E., Census Commissioner for India, "The Indian Census of 1911."

SIR JOHN O. MILLER, K.C.S.I., "The Central Provinces."

NEVILLE PRIESTLEY, Managing Director, South Indian Railway, "Indian Railways."

In the Colonial Section :—

W. A. LEGG, M.Inst.C.E., "Irrigation in South Africa."

ALAN H. BURGOYNE, M.P., "Colonial Vine Culture."

Of recent years it has been the practice that no medals should be awarded to readers of papers who had previously received medals from the Society. Acting on this rule the Council were precluded from considering the following papers :—

In the Ordinary Meetings :—

James Douglas, LL.D., "The Industrial Progress of the United States of America"; Cyril Davenport, F.S.A., "Illuminated MSS."; Leonard Hill, M.B., F.R.S., "The Influence of Ozone in Ventilation"; Frank Warner, "The British Silk Industry and its Development since 1903"; T. Thorne Baker, "Some Modern Problems of Illumination—the Measurement and Comparison of Light Sources"; William Burton, M.A., F.C.S., "Ancient Egyptian Ceramics."

In the Indian Section :—

Colonel Sir Thomas H. Holdich, K.C.M.G., K.C.I.E., C.B., D.Sc., "The North-East Frontier of India."

In the Colonial Section :—

The Hon. John G. Jenkins, "Australian Railways."

The Council, however, desire to express their high appreciation of these papers by thanking their authors for them.

Hosted by Google

THE ROYAL SOCIETY OF ARTS.*

By Sir Henry Trueman Wood, M.A.,
Secretary of the Society.

VIII.—The Society and the Fine Arts. (1755–1851.)

It has sometimes been suggested that the early offer of prizes to young artists was due to the fact that Shipley was a drawing-master, and that his principal object was to establish a society for the encouragement of painting and drawing, thereby serving his own professional interests. There is, however, no vestige of evidence of this in any of the Society's records. As before mentioned,† it was quite clearly stated that the reason for the offer was the belief of the founders of the Society that "the Art of Drawing is absolutely necessary in many employments, trades, and manufactures." It will also be remembered that Shipley himself controverted in the *Gentleman's Magazine*, in 1756, the idea that the intention of the Society was to train young people as artists, and declared that its main object was to fit young people for the pursuit of the industrial Arts.

The history of the origin of the Society's Fine Art prizes has already been told in the first article of this series.* It was there recorded how, out of the limited funds subscribed for the purpose of offering prizes, a certain portion was devoted to rewards for young people of both sexes in drawing, and how the first prizes were taken by Cosway the painter, Smart the engraver, Gresse the painter, and Barbara Marsden, the clever girl who afterwards married Meyer, one of the original members of the Royal Academy.

From this modest beginning there soon developed a well-organised system for the

* The previous articles of the series appeared in the *Journals* of June 9th and 16th, September 22nd and 29th, November 3rd, 1911, January 12th, 19th and 26th, and April 5th, 1912.

† *Journal*, June 9th, 1911, p. 770.

* *Journal*, June 9th, 1911, p. 770.

Sherwin's Design used as a Frontispiece for Vol. I. of the "Transactions" (see p. 751).

encouragement of Pictorial Art, which lasted for very nearly a hundred years, and had very real influence on the growth of English Art.

The prizes were at first intended to encourage Industrial Art, Art applied to manufactures, but it is not difficult to trace the changes in the Society's plans, which ended in the development of a scheme for encouraging young artists pure and simple.

In the first list of premiums, a list published as an advertisement in the newspapers, but only preserved by the Society in MS., prizes are offered to boys and girls under the age of seventeen, for "the most ingenious and best fancied designs, composed of Flowers, Fruit, Foliage, and Birds, proper for Weavers, Embroiderers, or Callico Printers."

In the oldest printed list of premiums, that issued in 1758, the objects of the Society in including "Premiums for improving Arts, etc.," are very clearly set out. "Fancy, Design and Taste, being greatly assisted by the *Art of Drawing*, and absolutely necessary to all Persons concerned in Building, Furniture, Dress, Toys, or any other Matters where Elegance and Ornament are required," it is "judged proper" to offer certain prizes to young persons, according to a schedule carefully drawn out, for drawings of the Human Figure, Landscapes, Casts, etc. Some of these are confined to students in "The Academy for Painting, etc., in *St. Martin's Lane*"; others are open to candidates who had studied in the Duke of Richmond's gallery, and others were quite open.

In the same list, besides these prizes for drawing, etc., we find special offers for designs for weavers and calico-printers, cabinet-makers, and coachmakers, as well as for manufacturers of iron, brass, china, earthenware, or "any other Mechanic Trade that requires Taste." All these were for young people. There was also a prize for a copper medal, "the medallic Art being capable of great Improvement in this Nation," open to candidates a little older, but still under twenty-five. All this goes to show that the founders of the Society were anxious to encourage the application of Art to industry, and were fully conscious of the need existing at the time for such encouragement.

During the next few years the list was extended by the addition of engraving, mezzotint, etching, wood-engraving (with which is included engraving on type-metal), gem-engraving, cameo-cutting, modelling in pastes (cameos), bronze-casting, mechanical drawing, architectural design, furniture design, etc. Many prizes were awarded under these various heads (Bewick got a prize of seven guineas in 1775), but, on the whole, the response was hardly satisfactory. The number of entries in the purely artistic classes was far more numerous, and the result was that by 1778 all the technical subjects had been practically dropped out, and the list confined to the artistic classes alone—including, of course, all the methods of reproduction, engraving, modelling, carving, casting, etc., but omitting the industrial applications. No doubt the Society moved in the direction of least resistance, and endeavoured to supply what the public demanded; but it is impossible to suppress a feeling of regret that the work so well begun was not continued, and that a furth [illegible] was not made to improve the artistic quality of the various industrial products then being manufactured in rapidly increasing amounts in England.

However, the Committee of Polite Arts evidently took greater interest in Art pure and simple than in its industrial applications, though some of them must have seen the importance of encouraging the "Lower branches of the Polite Arts, such as drawings for Patterns for Silk-weavers and Callico-printers," for in the observations appended in the list of Fine Art awards in the "Register of Premiums," etc., published in 1778, credit is claimed for the work done by the Society in the promotion of the application of Art to textile manufactures.

> "The elegance of pattern adopted by them [weavers and calico-printers] may with justice be attributed in a great degree to the rewards and attention bestowed upon them by the Society."

Nevertheless, the Society stopped its rewards and turned its attention elsewhere, practically abandoning the whole field of industrial Art. Now and again prizes were offered for designs. In 1801 "chints" patterns were asked for, and copper-plate patterns for calico-printers, but both offers were dropped after a few years, and it may be said with truth that very little was done to advance industrial Art until, a hundred years later, Prince Albert told a deputation from the then newly-formed Council of the Society, that "The department most likely to prove immediately beneficial to the public would be that which encourages most efficiently the application of the Fine Arts to our Manufactures." The result of this advice was that the Council arranged a special list of prizes for artistic manufactures; among which was one for "A plain and cheap Earthenware Tea Service

Hosted by Google

in one colour, consisting of Teapot, Basin, Milk-jug, Cup and Saucer, and Plate." This prize was taken by "Felix Summerly, of 12, Old Bond Street," the pseudonym or trade-name adopted by Henry Cole; and it has often been said that this tea-service was the origin of the 1851 Exhibition. Of this more will be said hereafter, for Cole's connection with, and services to, the Society belong to a much later chapter of its history.

The foundation of the Royal Academy in 1768 might seem to have left nothing for the Society of Arts to do, so far as the Fine Arts were concerned, and it is evident that those who were responsible for the direction of the Society's work were anxious to avoid any rivalry with the new Academy. They did not carry out the intention, which at one time appears to have been favoured, of confining the Society's work to the encouragement of industrial Art, and in all probability the suggestion was not very popular, and doubtless at the time appeared impracticable; but they did definitely restrict the artistic awards to young students either young people who "are intended hereafter to become artists," as the *Transactions* rather quaintly put it, or to young folk of the upper class who were studying Art as amateurs.

It appears to have been thought that the Society's work in encouraging Art might gradually have been dropped, and that it would have been taken over by the Royal Academy; but things worked out differently. The Academy wisely confined itself to the instruction of the best class of Art students, and insisted on a high standard in all whom it admitted to its instruction, while the Society continued to offer rewards to all who cared to enter for its competitions. The value of its work was soon realised. The rewards of the Society were evidently highly appreciated, and it became evident that there was a keen competition among the younger Art students for the Society's prizes, and that they provided a valuable incentive to such students, both professional and amateur.

At first only boys and girls were allowed to compete; then classes for rather older candidates were formed, and there were some special classes without limitation of age. But the general idea evidently was that the Society would be wise to confine its competitions to young people, so this was for the most part done; and at all events so far as drawing, painting and sculpture were concerned, the prizes were restricted to youthful candidates of both sexes. There were various classes, with various limitations of age, and from time to time the rules were modified. Sometimes special subjects were set; sometimes the young artists were allowed to choose their own. When they were permitted to send in works of their own choice they had to execute sketches of a similar character in the presence of examiners, to prove their capacity. The tests seem to have been quite fair, and the correctness of the adjudicators' judgment is sufficiently proved by the long list of distinguished artists who won the earliest successes in the Society's competitions.

At first nearly all the prizes were in money, but "In order to encourage a love of the Polite Arts, and excite an Emulation among Persons of

THE FELIX SUMMERLY TEA-SERVICE.*

Rank and Condition," there was included in the 1758 list an offer of a gold and a silver medal for drawings by "Young Gentlemen or Ladies under the age of Twenty," and a similar offer to those under sixteen. The same prizes were offered in the following year, but were not continued after that. In 1762, however, a still more exclusive class was introduced—perhaps the definition of "rank and condition" was found difficult—for gold and silver medals were offered for drawings by sons and daughters of peers or peeresses. This queer distinction was carried on almost, but not quite, continuously for many years, with the addition of another generation, grandchildren of the nobility being included. A good many awards were made under this regulation to youthful aristocrats.

In or before 1783 a class was added for "young gentlemen" or "young ladies," and it was added that it was intended for those who "may hereafter become Patrons or Patronesses of the Arts." It was not, therefore, open to professional artists or their children. The rules were varied from time to time, but the distinction of rank was kept up till 1839, after which the privileges of the nobility disappeared, and the only distinction drawn was between amateurs and professionals.

In the closing years of the eighteenth century the interest in this department of the Society's work evidently flagged. The number of premiums offered was not very large, and the list of awards was a short one. It seems likely that this was mainly due to the feeling before referred to, that the Royal Academy was the proper authority for controlling all Art education, and that the Society ought to relinquish to it the work it had initiated. However, it was soon found that there was a public demand for artistic education of a more elementary character than was provided by the Academy, and that the Society's prizes indirectly supplied this demand. The result was that the Society was influenced to provide what was demanded, and that the natural popularity of the Society's prizes led to great increase in the number of the awards. Whatever the cause, it is certain that this condition of things was soon changed, and by the end of the first quarter of the nineteenth century the section of "Polite Arts" had evidently grown to be the most popular part of the Society's work. As before mentioned, industrial Art, the application of Art to industry, received but scant attention. No doubt the Society was influenced by the general state of public opinion; but all branches of artistic industry were encouraged, so far as the award of prizes could encourage them. As regards drawing, painting, and sculpture, the prizes were confined to young people only; but in the case of such Arts as die-sinking, gem-engraving, cameo-cutting, casting in metals, wood-engraving, and even line or mezzotint engraving and etching, there were, as a rule, no limitations of age, and many of the best workers of the time looked for their recognition to the medals or premiums of the Society.

In the classes for drawing and painting the limitations of age (with a few rare exceptions in earlier years) were always preserved, the limit being twenty-five, though in some of the classes it was lower. By far the largest proportion of the prizes was taken by these young candidates, and contemporary press descriptions of the Society's prize distributions refer almost exclusively (when speaking of the Art awards) to the young people who came up to receive them from the President. So long as the system of premiums was continued, the award of prizes to young artists was an essential part of it. Even when it was being revised in the years before the 1851 Exhibition, with the avowed object of substituting the application of Art to industry for the cultivation of pictorial Art, the prizes for painting and drawing were not discontinued, and the names of numerous recipients of such prizes are to be found in the lists down to that of 1849. As mentioned in a previous article, there was no prize distribution of any sort in 1851; at the last distribution in 1853 only one solitary medal was given in the class of Fine Arts.*

On the whole, the result of the Society's efforts for the promotion of Art, during the first century of its existence, must be regarded as distinctly valuable. The same causes which gradually rendered less and less effective the general offer of prizes for inventions and discoveries, by no means applied in the case of Art. If the medals and money prizes of the Society had obviously no direct educational influence, they had without any question a very genuine value as a means of discovering hidden talent, as an incentive and stimulant to youthful effort, and as a much appreciated reward for success. Hundreds of young artists received from the Society the first recognition of their powers, and were thus encouraged to persevere in careers which in many cases led to reputation and success—in some to fame and fortune. And

* *Journal*, Vol. I. p. 365.

Hosted by Google

the prizes given were often of large amount, so as to afford substantial assistance to young artists. Prizes of ten, fifteen, and twenty guineas were common, and when they recognised cases of unusual merit the Committee did not hesitate to grant sums of fifty or a hundred pounds.

The best evidence of the value of the Society's Fine Art awards is to be found in the following list, selected from the very much longer lists of prize-winners. In it an attempt has been made to pick out those who afterwards became professional artists, and attained some amount of success in their profession. Some other names of persons who attained eminence or reputation have also been included. It will be seen that the list contains a great number of Royal Academicians and Associates, amongst them three Presidents—Sir Thomas Lawrence, Sir Charles Eastlake, and Sir John Millais; many of the best-known English engravers; several celebrated sculptors; numerous architects of eminence; a large proportion of our best-known medallists and gem-engravers; and besides these a very large number of artists of distinction in all classes. There are also many of reputation in their day, but now forgotten, and some who showed promise in their youth not fulfilled in after years. The 450 or so names printed below have been collected out of a list of about 3,000 awards, extending over a period of ninety-five years, 1755 to 1849. In the mass this represents a very considerable amount of volunteer labour, carried out by a committee of artists and amateurs, and it may certainly be regarded as reflecting very great credit on the institution by whose members it was faithfully undertaken.

AUSTIN'S DESIGN USED AS A FRONTISPIECE FOR THE PREMIUM LIST FOR 1803 (see p. 737).

The task has been one of some difficulty, and has involved a certain amount of labour. Though pains have been taken to ensure accuracy, it is certain that there must be many errors and inaccuracies in the list. Completeness was not to be expected, and it can only be hoped that not many names of importance have been overlooked. In many cases identification was not found to be possible, and no doubt in others awards may have been attributed to the wrong persons.

The accounts of the subsequent careers of the prize-winners are mainly based on Redgrave's and Bryan's well-known dictionaries. The notes about some of the medallists and gem-engravers are taken from Forrer's "Dictionary of Medallists." * The "Dictionary of National Biography" has, of course, been invaluable, though only a small proportion of the candidates attained its standard of distinction. Graves's "Dictionary of Exhibitors" has supplied numerous references. Dossie's list of the Society's awards down to 1775 contains a certain amount of biographical information, but the notes are unfortunately very brief.

The Society's rewards in the class of "Polite Arts," as in all the other classes, were at first always pecuniary. In 1756 it was determined to provide also "Honorary Premiums" in the form of gold and silver medals, but this decision was not carried into effect until 1758, by which time, after a good deal of discussion, a design for the medal had been approved and a die cut. The first medals were awarded in December of that year, and amongst them was a gold medal to Lady Louisa Augusta Greville for a landscape-drawing in Indian ink. This was the only medal awarded in the Art class in 1758, but after that year the awards of medals became numerous, at first only to amateurs, but later

* This Dictionary has not yet reached letter R, but Mr. Forrer has very kindly supplied some information which will appear in the later volumes.

Hosted by Google

to professional artists also. In 1766 it was decided to adopt a special sort of prize instead of medals or money for youthful candidates, and the "Honorary Palette" was devised. This was a miniature copy of an artist's palette, bearing on the obverse the Society's title, and on the reverse a scroll with the recipient's name. It was in two sizes (2½ inches and 2 inches long respectively), and was in gold and silver, sometimes in silver-gilt. The original restriction to young persons was not always observed.

In 1811 the "Isis Medal," a medal with the head of Isis, designed by Thomas Wyon, was introduced. At first it was intended to substitute this for the palette, but this idea was not carried out. Both medals and palettes were awarded for many years—in fact, as long as any Fine Art prizes were given; but it is not very easy to say what was their precise relative value. At the first institution of the medal, the two were of equal value, and the candidate was given the option of selection. The last award of a palette was in 1847. The Isis Medal was awarded in the last two distributions of awards in 1850 and 1853.* It will, therefore, be seen that the awards (other than money) given by the Society were:—The Society's medal (often called the "Large Medal"), in gold and silver; the Isis Medal (sometimes called the "Small Medal"), in gold and silver; the Palette, in two sizes and in both metals, also rarely in silver gilt. On a very few occasions the silver medal was "set in a gold border." There was also the Stock Medallion,† nearly always given for Architecture, but occasionally for Sculpture.

The "Premiums" mentioned in the following list are all money prizes. They vary in amount from £150 to a few pounds, when a given amount had to be divided in shares amongst a number of candidates. It has not been considered necessary, except in some special cases, to state the value of the prizes in the list. Sometimes a medal and a money prize were both given.‡

* In 1850 there were no Fine Art prizes, but the Isis Medal was given for some of the awards in Industrial Art. In 1853 it was given for some purely technical inventions.

† This was awarded under the bequest of John Stock, who in 1781 left £100 to the Society, with the condition that the interest should be applied for the promotion of Drawing, Sculpture, and Architecture.

‡ The subject with which this article deals was treated by Mr. H. B. Wheatley in the *Journal* in 1895 (Vol. XLIII. p. 797), and he gave a rather shorter but similar list, which has always been found both interesting and useful. The fact that, in order to ensure completeness, the whole work had to be done afresh, made the present writer's obligations to his predecessor rather less than he had hoped, but as far as possible he has utilised Mr. Wheatley's work, and has pleasure in acknowledging his debt.

Artists and others who received the Society's Medals and Prizes, 1755–1849.*

Absolon, John. Silver Palette in 1832 for a Portrait in Chalk. *Water-colour painter.* Treasurer N.W.C.S. Died 1895.

Adams, Francis. Premium in 1760 for a Drawing. *Portrait painter and engraver.* "Did not attain any excellence" (Redgrave).

Agar, John Samuel. Silver Palette in 1793 for Historical Drawing. *Portrait painter and engraver.*

Aglio, Augustine. Silver Medal in 1831 for a Bust. An Italian artist, who came to England in 1803 to assist William Wilkins, R.A., the architect of the National Gallery. Died 1857.

Alcock, J. Rutherford. Gold Medals in 1825 and 1826 for Anatomical Models in Wax (coloured). Sir Rutherford Alcock, K.C.B., Consul in China, and first Consul-General in Japan. He gave up medicine for diplomacy in 1837. He was for long a member of the Society, and from 1880 to 1883 one of its Vice-Presidents. In 1882 he read an important paper on the Opium Trade. He died in 1897.

Aliamet, Francis Germain. Premiums in 1764 and 1765 for Engravings. *Engraver.* Brother of the celebrated French engraver. Worked for Boydell and others. Died 1790.

Allason, Thomas. Gold Medallion in 1810 for a Design for an Academy of Arts. *Architect.* Alliance Fire Office in Bartholomew Lane said to be his chief work (Redgrave).

Andras, Catherine. Silver Palette in 1801 for Models of Princess Charlotte and of Lord Nelson. *Medallist.* Modeller in Wax to Queen Charlotte. Produced Portrait Medallions in the enamelled paste of Tassie (q.v.), under whom she probably studied.

Artaud, William. Silver Palette in 1776, 1777, and 1782 for Drawings. *Painter of portraits and historical pictures.* Exhibited at Royal Academy up to 1822.

Austin, Richard. Silver Medal in 1802, Silver Medal (and 10 guineas) in 1803, and Silver Palette in 1804 for Wood Engraving. The 1803 medal was for a wood-cut (reproduced on page 736), "England, Scotland, and Ireland receiving the offerings of Genius, alluding to the rewards of this Society," used as a frontispiece to the Premium List for the year (1803), and printed in Vol. XXI. of the *Transactions* (facing page 1). *Wood Engraver.* Pupil of Bewick. "He was a clever artist, and much employed by the booksellers, but he did nothing to promote the art" (Redgrave).

Bacon, John. Premium in 1759 (aged eighteen) for a figure of Peace; subsequent awards were made to him in 1760, 1761, 1764 (two), 1765, 1772,

* The Secretary will be grateful for any corrections in this list, or for references to any additional names which might be included.

Hosted by Google

1774, 1776, 1777 and 1778, all for Casts or Models. In 1778 he was also presented with a Gold Medal in recognition of his gift to the Society of the statues of Mars and Venus. An engraving of his Mars, by Bartolozzi, is prefixed to Vol. V. of the *Transactions*, and one of his Venus to Vol. VII. *Sculptor*. R.A. Eminent and popular in his own day. Carried out many important works and monuments. The Mars and Venus are now in the Victoria and Albert Museum. Died 1799.

Baillie, Edward. Silver Medals in 1833 and 1837 for Enamel Painting. *Glass painter*. Exhibited in 1851 exhibition. Died 1856.

Baily, E. Hodges. Silver Medal in 1808 for a Plaster Cast of the Laocoon. A pupil of Flaxman. *Sculptor*. R.A. Retired 1863 and died 1867.

Ballantyne, John. Silver Medal in 1833 for a Drawing from an Antique Statue. *Copyist and Portrait Painter*. R.S.A. Died 1897.

Banks, Charles. Premiums in 1764, 1765, 1767 and 1768 (two) for Bas-reliefs. *Sculptor*. Brother of Thomas Banks, R.A. R.A. Gold Medallist 1774. Exhibited at Royal Academy 1775–1792.

Banks, Thomas. Premiums in 1763, 1765 and 1766 for Bas-Reliefs; Premiums in 1769 for a Cast and for a Design for Furniture. *Sculptor*. R.A. Monuments in St. Paul's and in Westminster Abbey. "Takes high rank among England's sculptors" (Redgrave). Died 1805.

Barney, Joseph. Silver Palette in 1774 for a Drawing of Flowers; Gold Palette in 1781 for Historical Drawings. *Fruit and flower painter*. Exhibited at Royal Academy 1786–1827. Drawing Master at Royal Military Academy.

Barralet, John James. Gold Palette in 1774 for a Landscape. *Water-colour painter*. Exhibited at Royal Academy from 1770. Died in America about 1812.

Barret, George. Premium in 1764 (£50) for a Landscape Painting. *Landscape painter*. R.A. One of the founders of the English school of water-colour painting. A painter who "enjoyed great reputation in his lifetime, which his works have not since maintained" (Redgrave). Died 1784.

Barret, Joseph. Gold Palette in 1775 for an Ornamental Design. Gold Palette in 1777 for Landscape Drawing. *Landscape painter*. Son of George Barret, R.A. Exhibited at Royal Academy 1785–1800.

Barron, Hugh. Premiums in 1759, 1761, 1765 and 1766 for Drawings. *Portrait painter*. Exhibited at Royal Academy 1782–1786. "The first amateur violinist of his day" (Redgrave). Died 1791.

Barron, William Augustus. Premium in 1766 for a Chalk Drawing; Silver Palette in 1774 and Gold Palette in 1775 for Landscapes. *Landscape painter*. Brother of Hugh Barron and like him a musician. Exhibited at Royal Academy 1774–1777.

Barry, James, R.A. Gold Medal and 200 guineas in 1798, "In testimony of his public zeal and eminent abilities, manifested in the series of Pictures in the Great Room of the Society."

Bassett, Henry. Gold Medal in 1823 for a Design for British Museum; Gold Medallion in 1825 for a Design for a Church. *Architect*. Exhibited at Royal Academy down to 1844.

Beauvais, John. Premium in 1765 for a Drawing. *Miniature painter*. A native of France. "Practised with success as a miniature painter at Bath" (Redgrave).

Behnes, William. Silver Medal in 1814 for an Outline of the Gladiator Repellens; Gold Medal in 1819 for the invention of an Instrument for Transferring Points to Marble. *Sculptor*. He was originally a portrait painter, but afterwards obtained considerable fame as a sculptor, and was specially successful with his busts. Exhibited at Royal Academy 1815–1863. Died 1864.

Bellingham, John. Premiums in 1758 and 1759 for Ornamental Designs; in 1760, 1761 and 1763 for Drawings. *Draughtsman and drawing-master*.

Bentley, Charles. Silver Medal in 1826 for Landscape in Water-colour. *Water-colour painter*. Member Water-colour Society and constant exhibitor. Died 1854.

Benwell, Sarah. Silver Palette in 1806 for a Drawing. Mentioned by Peter Pindar. Redgrave thinks the poet really referred to her sister, Mary Benwell, a better known artist.

Berridge, John. Premiums in 1766 and 1767 for Drawings. *Portrait painter*. Pupil of Sir Joshua Reynolds. Exhibited at Royal Academy 1785.

Bewick, Thomas. Premium in 1775 (seven guineas) for an allegorical Vignette on Wood. The great wood-engraver must have been just out of his apprenticeship, as he was born in 1753. Died 1828.

Biffin, Sarah. Silver Medal in 1821 for an Historical Miniature. Miss Biffin, although born without hands or feet, succeeded in making a name for herself as a miniaturist.

Billings, Robert William. Six Medals for Architectural Pictures. Silver Medal in 1833 for a Drawing; Silver Medal in 1835 for an Engraving; Silver Medal in 1836 for a Water-colour Drawing; Silver Medal in 1838 for an Oil Painting; Gold Medal in 1837 for an Etching; Gold Medallion in 1839 for "an analysis of the great east window of Carlisle Cathedral." *Architect*. Writer on architecture and archæology. Died 1874.

Birch, William. Silver Palette in 1784 for Pictures in Enamel. *Enamel painter and engraver*. Went to America and died in Philadelphia. Painted miniature of Washington.

Blackmore, John. Silver Palette in 1772 for a Drawing. *Mezzotint engraver*. Engraved some of Sir Joshua Reynolds's portraits. Died about 1780.

Hosted by Google

Blore, Edward. Silver Medal in 1809 for a Drawing of Fotheringham Church. *Architect.* F.R.S. Built Sir Walter Scott's house at Abbotsford. Architect to King William IV. and to Queen Victoria. Designed the front of Buckingham Palace. Died 1879.

Bond, John Daniel. Premiums in 1764 and 1765 for Landscapes. *Landscape painter.* "Resided chiefly at Birmingham, where he conducted the decorative branch of some large manufactory" (Redgrave). Died 1803.

Bonner, Thomas. Premium in 1763 for an Etching of a Landscape. *Topographical draughtsman and engraver.* Illustrated several topographical works. Exhibited at Royal Academy in 1807.

Bonomi, Joseph. Silver Medal in 1815 for a Bas-relief. *Architect.* Son of Joseph Bonomi, A.R.A.

Bouvier, Augustus Jules. Silver Medal in 1841 for a Chalk Drawing. *Water-colour painter.* Died 1881.

Boydell, John. Gold Medal in 1773 for Encouraging the Art of Engraving. *Engraver and publisher.* Published celebrated "Shakespeare Gallery." Lord Mayor 1790. Died 1804.

Brandenburgh, Anspach, and Bareith, etc., The Margravine of (previously Lady Craven). Silver Medal in 1806 for a Model in Bas-relief of the late Margrave.

Branston, Allen Robert. Silver Palette in 1806 and Silver Medal in 1807, both for Wood-engraving. *Wood-engraver.* Died 1827.

Branwhite, Charles. Silver Medal in 1837 for a Figure in Bas-relief. *Landscape painter.* Died 1880.

Brigstocke, Thomas. Silver Medal in 1826 for a Chalk Drawing; Silver Medal in 1827 for an Oil Painting. *Portrait painter.* Exhibited at Royal Academy from 1842. Died 1881.

Brockedon, William. Silver Medal in 1823 for a Rest for painters engaged in minute work. *Subject and history painter.* He was an F.R.S. and made various inventions, some of which were patented. He received another Medal for a Surgical Apparatus in 1825. He was Chairman of the Committee of Polite Arts from 1824 to 1831. "He displayed no ordinary talent in the various departments of painting — historical, landscape, and portrait" (Bryan). His portrait by himself is in the Uffizi. Died 1854.

Bromley, James. Silver Palette in 1821 for an Etching. *Mezzotint engraver.* Engraved many well-known portraits. Died 1838.

Bromley, John Charles. Two Silver Palettes and a Silver Medal in 1808, 1809, and 1810 for Etchings. *Mezzotint engraver.* He was born in 1795, so that he cannot have been more than fourteen when he took his first prize. Died 1839.

Bromley, William, A.R.A. Gold Medal 1821 for an Historical Engraving. This was not an award to a student, for Bromley had been an Associate Engraver of the Royal Academy since 1819. He was the father of J. C. Bromley and of James Bromley. Died 1842.

Browne, Hablot. Silver Medal in 1832 for a Group of Figures in Pencil; Silver Medal in 1833 for a "Free Etching of historical composition." Two years before he gained his first medal (at the age of seventeen) he began the association with Dickens on which his reputation was founded. Under the well-known signature of "Phiz" he illustrated the latter part of "Pickwick," "Nicholas Nickleby," "Martin Chuzzlewit," "Dombey," "Copperfield," "Bleak House," "Little Dorrit," and "A Tale of Two Cities" (Bryan). Died 1882.

Browne, John. Premium in 1763 for a Drawing. *Engraver.* A.R.A. Apprenticed to Tinney the printseller, and to Woollett. Exhibited at Royal Academy 1771–1783. Died 1801.

Bryer, Henry. Premium in 1762 for an Etching. Premiums in 1763 and 1764 for Engravings. *Engraver.* Engraved some of Angelica Kauffman's pictures. Pupil and partner of W. W. Ryland. Died 1799 according to Redgrave and Bryan, but Dossie in the list published in 1783 speaks of him as dead.

Bunning, James Bunstone. Silver Medal in 1822 for a Drawing of Bow Church. *Architect.* Surveyor to Foundling Hospital, architect to Corporation of London. Amongst his chief works were Billingsgate Market, Coal Exchange, Islington Cattle Market. Died 1863.

Burch, Edward. Premiums in 1762, 1763 and 1765 for Gem Engraving. *Sculptor and medallist.* R.A. "As a gem engraver he was unrivalled in his day" (Redgrave). Died 1814.

Burgess, Thomas. Silver Palette in 1771 and 1773 for Drawings. *Portrait painter and teacher.* "Mr. Burgess's Academy in Maiden Lane produced many able claimants for the Society's awards" (Dossie). Exhibited at Royal Academy 1778–1786.

Burgess, William. Premium in 1761 for a Drawing. *Portrait painter and teacher.* He was connected with Thomas Burgess's Academy in Maiden Lane and was probably related to him. Exhibited at Royal Academy 1774–1799. Died 1812.

Burt, Albin R. Silver Medal in 1830 for a Portable Easel. *Engraver and portrait painter.* Produced a print of Emma, Lady Hamilton. Died 1842.

Buss, Robert William. Silver Medal in 1826 for a Portrait in Oil. *Portrait and subject painter.* Illustrated numerous books. Exhibited at Royal Academy 1826–1859. He was employed to make illustrations for "Pickwick" after the death of Seymour, and before Hablot K. Browne (Phiz) took up the work, but his engravings were not used. Died 1875.

Byrne, William. Premium in 1765 for an Engraving. *Landscape engraver.* Engraved Hearne's (q.v.) drawings for the "Antiquities of Great Britain." "May be justly ranked among our eminent engravers of landscape" (Bryan). Died 1805.

Hosted by Google

Calvert, Frederick. Silver Medal in 1833 for an Oil Painting. *Topographic draughtsman.* Published various series of views, etc.

Carr, Johnson. Premiums in 1757, 1758, 1759 and 1764 for Drawings of Figures; Premiums in 1760, 1761 (two), 1762 and 1763 for Landscape Drawings. Pupil of Richard Wilson, R.A. He died young, at the age of twenty-two. "This promising young man, at the early period of twenty-one years, executed drawings equal to those of the ablest masters then in this country. He died, much regretted, in 1764" (Dossie).

Carter, James. Silver Medal in 1819 for Architectural Drawing. *Engraver.* Engraved for the Annuals and for the Art Union. Died 1855.

Casali, Andrea. Premiums (100 and 50 guineas) in 1760, 1761, 1762 and 1766 for Historical Oil Paintings. *Historical painter.* Casali was an Italian who came to England before 1748, and returned to Italy about 1766. He painted an altar-piece for the Foundling Chapel, some pictures for St. Margaret's, Westminster, some ceilings at Fonthill, etc.

Chalon, Maria Ann. Silver Palette in 1813 for a Drawing; Silver Medal in 1818 for a Painting. *Miniature painter.* Daughter of H. B. Chalon, the animal painter. She was miniature painter to the Duke of York, and an exhibitor at the Royal Academy.

Chamberlin, Mason. Premium (50 guineas) in 1764 for an Historical Oil Painting. *Portrait painter.* R.A. His portrait of Dr. Hunter is in the Royal Academy, and his portrait of Dr. Chandler at the Royal Society. Died 1787.

Cheesman, Thomas. Silver Palette in 1781 for a Drawing; Gold Medal in 1814 for an Engraving. *Engraver and draughtsman.* One of Bartolozzi's best pupils. Exhibited drawings and portraits at Royal Academy 1802–1820. Engraved Hogarth's "Lady's Last Stake."

Clack, Richard Augustus. Silver Medal in 1825 for a Landscape; Silver Medal in 1826 for a Portrait. *Portrait painter.* Exhibited at Royal Academy 1830–1856.

Clennell, Luke. Gold Palette in 1806, and Gold Medal in 1809, both for Wood Engraving. *Wood engraver and subject painter.* He was apprenticed to Bewick, and succeeded as a wood-engraver, but abandoned that art for painting. Exhibited at Royal Academy 1812–1816. Became insane in 1817. Died 1840.

Clevely, John. Premium in 1765 for a Sea Painting in Oil. Silver Palette in 1774 for a View of a Castle in the Isle of Wight. *Marine painter.* Exhibited at Royal Academy 1770–1786. Draughtsman to Captain Phipps's Arctic Expedition, and illustrated the Journal of the voyage. Died 1786.

Clint, George. Gold Medal in 1819 for an Historical Engraving. *Portrait painter and engraver.* A.R.A. Died 1854.

Clint, Raphael. Gold Medal in 1825 for an Intaglio of a Head. *Gem engraver.* Son of George Clint, A.R.A. "Possessed considerable talent" (Bryan).

Clint, Scipio. Gold Medals in 1824 and 1826 for Medal Dies. *Medallist.* Son of George Clint, A.R.A. Medallist to the King. Died 1839 at the age of thirty-four.

Coleman, William. Premiums in 1775, 1776 and 1777 for Engraving on Wood. *Wood engraver.* Died 1807.

Collyer, Joseph. Premium in 1761 for a Drawing. *Engraver.* A.R.A. Engraved some of Sir Joshua Reynolds's portraits, also for Boydell. He was about thirteen when he took the prize. Died 1827.

Cook, Richard. Gold Palette in 1802 for a Drawing of Mucius Scævola. *History painter.* R.A. Died 1857.

Cook, Thomas. Premium in 1761 for a Drawing; Silver Palette in 1770 for a Drawing. *Engraver.* "Rose to the very top of his profession" (Redgrave). Worked for Boydell. Died 1818.

Cooley, Thomas. Premiums in 1763, 1764 and 1765 for Architectural Designs. *Architect.* Built the Royal Exchange in Dublin, and other buildings in Ireland. Died 1784.

Cope, Charles West. Silver Medal in 1828 for a Finished Drawing from a Statue; Silver Medal in 1829 for an Oil Painting. *Historical painter.* R.A. The portrait of Prince Albert in the Society's meeting-room was painted by Cope. Died 1890.

Corbaux, Fanny. Silver Medal in 1827, and Gold Medal in 1830 for Miniatures; Silver Medal in 1829 for a Water-colour. *Water-colour painter.* Exhibited numerous pictures at Royal Academy, and also at the New Water-Colour Society. Writer on Oriental Subjects and Biblical Exegesis. Died 1883.

Corbaux, Louisa. Silver Medal in 1828 for a Drawing; Silver Medal in 1829 for a Water-colour. *Water-colour painter.* Sister of Fanny Corbaux. Exhibited at Royal Academy, but more frequently at New Water-Colour Society.

Corbould, George. Silver Palette in 1806 for a Drawing. *Engraver.* Brother of H. Corbould. Died 1846.

Corbould, Henry. Gold Palettes in 1804 and 1805, both for Historical Drawings. *Historical painter and draughtsman.* He prepared the drawings of the Elgin Marbles. Died 1844.

Cosway, Richard. Premium in 1755 for a Drawing in Chalk, the First Prize in the Society's first competition; Premium in 1757 for an Ornamental Design; Premiums in 1758, 1759 and 1760 for Drawings. *Miniature and portrait painter.* R.A. A pupil of Shipley. The Society possesses two portraits by him, Shipley and Templeman. Died 1821.

Hosted by Google

Cotman, John Sell. Silver Palette in 1800 for a Drawing. *Landscape and marine painter.* Worked both in oil and water-colour. Exhibited at Royal Academy. Lived some time in Norfolk, and much of his work was done in that county. Died 1842.

Cousins, Samuel. Silver Palette in 1813, and Silver Medal in 1814, both for drawings. His first award was obtained when he was eleven years old. *Engraver.* R.A. "His *œuvre* consists in all of about 200 plates" (Bryan). An apprentice and assistant of S. W. Reynolds, the engraver, he lived to engrave Millais's "Cherry Ripe." Died 1887.

Crellin, Henry Pickersgill. Premium in 1820 for a Drawing. Nephew of H. W. Pickersgill, R.A. Did not follow artistic pursuits, but practised as a medical man. Brother of H. N. Crellin. Died about 1843.

Crellin, Horatio Nelson. Premium in 1819 for a Drawing. *Engraver.* Gave up the pursuit of Art and became a medical man. Died about 1881.

Cross, Richard. Premium in 1758 for a Drawing. *Miniature painter.* Exhibited at Royal Academy 1770–1795. Died 1810.

Dall, Nicholas Thomas. Premium in 1768 for a Landscape. *Landscape painter.* A.R.A. He was a Dane, and settled in London about 1760. Was a scene painter at Covent Garden Theatre before his election into the Royal Academy. Died 1777.

Daniell, Thomas. Premium in 1780 for Landscape Painting. *Landscape painter.* R.A. Painted in India for ten years, and made his reputation by Indian views. Died 1840.

Davis, John Scarlett. Silver Palettes in 1816 for an Engraving, and in 1821 for a Head in Pen-and-Ink. *Subject painter.* Successful as a painter of interiors. Exhibited at Royal Academy 1825–1841. Died 1841.

Dean, Hugh Primrose. Premium in 1765 for a Landscape. *Landscape painter.* Exhibited at Royal Academy 1777–1780. Died about 1784.

Deare, Joseph. Silver Medal in 1823 for a Plaster Model. Two Silver Medals in 1824 for a Bas-relief, and for a Copy of a Group. *Sculptor.* Exhibited at Royal Academy 1825–1832.

De la Motte, William. Silver Medal in 1821 for an Etching. *Water-colour painter.* Pupil of West. Exhibited at Royal Academy 1796–1848. Drawing-master to Royal Military Academy. Died 1863.

Denman, J. Flaxman. Silver Palette in 1822 for a Drawing in Indian ink. *Subject painter.* Exhibited at Royal Academy in 1839. Presumably a relation of Mrs. Flaxman.

Denman, Maria. Silver Medal in 1807 for her Drawing of Flaxman's Design for the Society's Medal, printed as the Frontispiece to Vol. XXV. of the *Transactions;* Silver Medal, also in 1807, for "a Beautiful Plaster Model of a Cupid's Head." She was the sister of Flaxman's wife, and his adopted daughter. She founded the Flaxman Gallery at University College, London.

Denman, Thomas. Silver Palette in 1807 for a Plaster Model. *Sculptor.* Exhibited at Royal Academy and elsewhere 1815–1837. Possibly Mrs. Flaxman's brother.

Derby, Louisa. Silver Medal in 1828 for a Pencil Drawing of a Landscape by Claude. She afterwards married Henry Room, a portrait painter of some reputation. Their eldest son, Howard Henry Room, was a valued official of the Society from 1861–1900.

Devis, Antony. Premium in 1763 for a Landscape. *Landscape painter.* Exhibited at Royal Academy 1772 and 1781. Died 1817.

Dickinson, William. Premium in 1767 for a Mezzotint of R. E. Pine's Portrait of King George II. *Engraver.* Engraved after West, Morland, Stubbs, Reynolds, etc. Died 1823.

Dighton, Denis. Silver Medals and Palettes in 1807, 1808, 1810 and 1811 for Drawings and an Oil Painting (Battle of Agincourt). *Battle painter.* Exhibited at Royal Academy 1811–1825. Son of Robert Dighton. Died 1827.

Dighton, Robert. Silver Palette in 1768 for a Fancy Head in Pen-and-Ink after Worledge. *Portrait painter and drawing master.* Exhibited at Royal Academy 1775–1777. Died 1814.

Dobson, William Charles Thomas. Silver Medal in 1841 for an Oil Painting, "The Prodigal Son." *Painter in oil and water-colour.* R.A. Died 1898.

Donaldson, John. Premium in 1764 for an Historical Painting; two Premiums in 1768 for Enamels. *Miniature painter.* Apparently a man of varied accomplishments, but unsettled and wanting in application. He seems to have failed in life, and died in poverty 1801.

Donaldson, Thomas Leverton. Silver Medal in 1815 for an Original Architectural Design. *Architect.* P.R.I.B.A. Author of works on architecture. Died 1885.

Downman, John. Premium in 1779 for an Historical Painting. *Portrait and subject painter.* A.R.A. Died 1824.

Dubourg, Richard. Premium in 1755, at the first of the Society's competitions, at the age of fourteen, for a Drawing. Dossie says that he devoted himself to the reproduction of examples of ancient Italian architecture, and had some sort of exhibition of reproductions in cork of "Venerable Remains of Antiquity." His name does not appear in Redgrave or Bryan.

Dunkarton, Robert. Premiums in 1761, 1762, 1763, 1764, 1765 and 1766 for Drawings of various sorts; Premium in 1767 for an Engraving of Chamberlin's Portrait of Dr. Chandler, the antiquary and traveller (now in the possession of the Royal Society). *Mezzotint*

Hosted by Google

engraver. Exhibited portraits at Royal Academy 1774-1779. "As a mezzotintist . . . he was rarely surpassed" (Redgrave). Engraved portraits by Reynolds, West, and others.

Durant, Susan. Silver Medal in 1847 for an Original Plaster Bust. *Sculptor.* Exhibited at Royal Academy 1847-1866. The Princess Louise was her pupil. Died 1873.

Durnford, Elias. Premium in 1755 for a Drawing of Flowers (third prize in the class between fourteen and seventeen); Premium in 1757 for an Ornamental Design. Went to America, and became Lieut.-Governor of Pensacola (Dossie).

Durno, James. Premiums in 1762 and 1765 for Drawings; Premiums in 1766, 1770 and 1773 (100 guineas) for Oil Paintings. *Historical painter.* Died in 1795 in Rome, where he lived from 1774.

Earlom, Richard. Premiums in 1757 (under fourteen years of age), 1758, 1759, 1760, 1761, 1762, 1763, 1764 and 1765 for Drawings in various classes; Premium in 1766 for an Etching. *Engraver.* A pupil of Cipriani, and afterwards one of the most distinguished of English engravers. "His 'Liber Veritatis,' comprising mezzotint engravings after 200 drawings by Claude, published in 1777, is well known" (Redgrave). Died 1822.

Eastlake, Charles Locke. Silver Medal in 1810 for a drawing of Cupid and Psyche. *Historical painter.* Sir Charles Eastlake, P.R.A. Director of the National Gallery. He acted as Chairman of the Society's Committee which procured the passing of the "Art Copyright Act, 1862." Died 1865.

Eckstein, John. Premiums in 1761 and 1764 (50 guineas) for Bas-reliefs. *Modeller and portrait painter.* Exhibited wax models and portraits at Royal Academy 1770-1798.

Eddis, Eden Upton. Silver Medal in 1828 for a Drawing. *Portrait painter.* Gold Medallist R.A. 1837. Exhibited at Royal Academy 1834-1881. Popular and successful artist. His portrait of Theodore Hook is in the National Portrait Gallery. Died 1901.

Edwards, Edward. Premium in 1762 for a Drawing; Premiums in 1764 and 1765 for Historical Pictures; Gold Medal in 1770 for an Historical Painting; Premium in 1781 for a Landscape. *Portrait and subject painter.* A.R.A. Teacher of perspective at Royal Academy. Published "Anecdotes of Painters," a supplement to Walpole's work. Died 1806.

Edwards, John. Premiums in 1757 for a Drawing; in 1760 for an Ornamental Design; in 1760 for a Landscape Drawing; in 1761, 1762, 1763, and 1767 for Drawings of Flowers; in 1764 for an Historical Drawing; Gold Palettes in 1769 for a Figure Drawing, and in 1771 for a Drawing of Flowers. *Historical and flower painter.* Pupil of Maberley.

Eggbrecht, John E. Silver Medal in 1821 for a Chalk Drawing; Silver Medal in 1824 for an Oil Painting. *Painter of still life.* Exhibited at Royal Academy 1826-1828.

Engleheart, Thomas. Premium in 1777 for a Model of a Human Figure. *Sculptor and modeller in wax.* Exhibited at Royal Academy 1773-1786. Gold Medallist R.A. 1772.

Engleheart, Timothy Stansfeld. Silver Palette in 1821 for a Chalk Drawing. *Line engraver.* Engraved for the annuals. Son of Francis. Died 1879.

Engleheart, William Francis. Silver Palette in 1798 for an Outline Drawing. *Engraver.* Engraved after Stothard, Cook and Smirke. Died 1849.

Ensom, William. Silver Medals in 1815 and 1816 for Pen-and-Ink Drawings. *Engraver.* Died 1832.

Fairland, Thomas. Silver Medals in 1822 and 1823 for Drawings. *Engraver, lithographer and portrait painter.* Died 1852.

Falconet, Peter. Premium in 1766 for an Historical Painting; Premium in 1768 for an Oil Painting. *Portrait painter.* Exhibited at Royal Academy in 1773.

Farey, Joseph. Silver Palette in 1809 for an "Original Drawing of a Steam Engine"; Silver Palette in 1809 for a "Perspective Drawing of London Bridge Water-works." *Engineer and draughtsman.* He was the son of John Farey, geologist and consulting surveyor, and the brother of John Farey, jun., a civil engineer of eminence, who received a Gold Medal from the Society for his ellipsograph. As a young man, John Farey supplied mechanical drawings to various works, and some of the illustrations in Vols. XXVI. to XXXI. of the *Transactions* are by him. It is possible that some may also be by Joseph, as the initials of the brothers are the same. Joseph Farey later on took over part of his brother's work. He died about 1829.

Farington, George. Silver Palette in 1770 and 1771 for Landscapes; Silver Palette in 1771 for a Drawing. *History painter.* Brother of Joseph Farington, R.A. Pupil of West. Gold Medallist R.A. 1780. Exhibited at Royal Academy in 1773 and 1783. Died 1788.

Farington, Joseph. Premiums in 1764, 1765 and 1766 for Landscape Drawings. *Landscape painter.* R.A. Illustrated Boydell's great work on the "History of the Thames." Died 1821.

Faulkner, B. Premiums in 1819, 1820 and 1822 for Die Engraving. *Medallist.* Forrer mentions several of his medals, all produced in or before 1826. He suggests that he may have been identical with B. R. Faulkner, a portrait painter of reputation, who exhibited at the Royal Academy 1821-1849, but this is improbable, for the Faulkner (or Faulkener) who took the prizes lived in Birmingham, whereas B. R. Faulkner was at the time living in Newman Street, London.

Hosted by Google

Feary, John. Premiums in 1766 for a Drawing and in 1776 for a Landscape. *Landscape painter.* Exhibited at Royal Academy 1772–1788. Painted views of gentlemen's seats and parks.

Fennell, John G. Silver Medal in 1827 for a Chalk Drawing. *Engraver.* Pupil of Henry Sass. Superintended the Findens's establishment.

Finden, Edward. Silver Palette in 1810 for an Outline of the Laocoon. *Engraver.* Younger brother of William Finden. Died 1857.

Finden, William. Silver Palette in 1807 and Silver Medal in 1808 for Drawings; Gold Medal in 1813 for an Engraving. *Engraver.* The two Findens, Edward and William, worked together. They engraved some of Landseer's and Wilkie's works, and produced many illustrations for books. Died 1852.

Finlayson, John. Premium in 1764 for an Enamel Painting; Gold Palette (and 30 guineas) in 1773 for his Mezzotint of Sir Joshua Reynolds's Portrait of Lord Romney. *Mezzotint engraver.* Engraved Portraits after Hone, Coates, Zoffany and Reynolds. Died about 1776.

Flaxman, John. Premium in 1766 (at the age of eleven) for Modelling in Clay; Premiums (two) in 1769 for the same; Gold Palette in 1770 for Modelling a Statue of Garrick; Gold Medal in 1807 for Designing the Society's Medal and presenting it to the Society. In the latter year a Silver Medal was awarded to his sister-in-law, Miss Maria Denman (q.v.), for a Drawing of the Medal, which forms the Frontispiece to Vol. XXV. of the *Transactions* (1807). *Sculptor.* R.A. Died 1826.

Fox, Charles. Silver Medal in 1847 for an original Composition in Plaster. *Modeller.* Died 1854.

Freebairn, Alfred Robert. Silver Palette in 1810 for a Drawing. *Engraver.* "Chiefly known by his engraving of Flaxman's 'Shield of Achilles'" (Bryan). Died 1846.

Frith, William Powell. Silver Medal in 1836 for Drawing in Chalk from a Bust; Silver Medal in 1837 for a finished Drawing from a Cast. *Subject painter.* R.A. Painter of the celebrated and popular pictures, "The Derby Day," "The Railway Station," "Margate Sands," etc. Frith was born in 1819, so he must have been about seventeen when he received his first award. Died 1909.

Frost, William Edward. Silver Medals in 1829, 1830 and 1831 for Drawings; Silver Medal in 1832 for Composition in Oil in Still Life; Gold Medal in 1834 for a Portrait in Oil. *Subject painter.* R.A. Died 1877.

Gahagan, Sebastian. Premium in 1777 for a Model. *Sculptor.* Assistant to Nollekens. Exhibited at Royal Academy 1816–1835. The Duke of Kent's statue at the top of Portland Place is by him.

Gandon, James. Premiums in 1757 for a Drawing; in 1758 for a Design for Weaving; in 1759 for a Landscape; in 1762, 1763 and 1764 for Architectural Designs. *Architect.* Exhibited at Royal Academy 1774–1780. Carried out important works in Dublin. Died 1823.

Gardner, Rev. John. Premium in 1767 for a Landscape in Oils. *Amateur.* Vicar of Battersea. Died 1808.

Garvey, Edmund. Premiums in 1769 and 1771 for Landscapes. *Landscape painter.* R.A. Died 1813.

Geddes, Margaret. Silver Medal in 1812; Gold Medals in 1813 and 1814 for Oil Paintings. *Portrait painter,* "who secured great reputation" (Bryan). She married W. H. Carpenter, Keeper of Prints and Drawings in the British Museum. Three of her portraits are in the National Portrait Gallery. Died 1872.

Godby, James. Silver Palette in 1787 for an Outline Drawing. *Engraver.* Illustrated "Fine Arts of the English School," 1812, etc.

Goldicutt, John. Silver Medallion in 1815 for an Architectural Design. *Architect.* Secretary R.I.B.A. Published an account of the Pompeian paintings, etc. Died 1842.

Gooch, Thomas. Silver Palette in 1778 for Drawings of Animals. *Animal painter.* Exhibited at Royal Academy 1781–1802, principally portraits of horses and dogs.

Goodall, Edward. Silver Medal in 1837 for a Water-colour Painting. *Water-colour painter.* Brother of F. Goodall, R.A.

Goodall, Frederick. Silver Medal in 1837 for Water-colour Drawing; Silver Medal in 1838 for Oil-painting, "Interior of Thames Tunnel." He was not sixteen when this, his first oil-painting, was produced. It led to a friendship with Sir Isambard Brunel and to a visit to Normandy, where he found the materials for his first Royal Academy picture, "French Soldiers Playing at Cards," exhibited 1839. From that date his career was one of successful and deserved popularity. *Subject painter.* R.A. Died 1904.

Gott, Joseph. Silver Palette in 1808 for Original Plaster Cast. *Sculptor.* Gold Medallist R.A. 1819. Exhibited at Royal Academy 1820–1848.

Graham, George. Silver Palette in 1780 for a Drawing. *Engraver.* Produced book illustrations, etc.

Grant, William. Silver Palette in 1837 for a Pencil Drawing. *Historical painter.* Exhibited at Royal Academy 1847–1866. Died 1866.

Green, Benjamin Robert. Silver Palette in 1824 for a Chalk Drawing; Silver Medal in 1825 for an Outline Drawing; Silver Medal in 1827 for a Portrait in Oil. *Water-colour painter.* Died 1876.

Gresse, John Alexander. Premium in 1755 (aged twelve) for a Drawing; Premiums in 1756, 1757, 1758, 1759 (three), 1761, and 1762 for Drawings; Premium in 1769 for a Landscape

Hosted by Google

in Oils. *Water-colour painter.* Fashionable drawing-master. Taught the daughters of George III. Died 1794.

Greville, Lady Louisa Augusta. Gold Medals in 1758, 1759 and 1760 for Drawings. She was the first to take one of the honorary awards offered to amateurs. Gold Medal in 1759 for an Etching. She was a daughter of the eighth Earl of Warwick, and an amateur of considerable skill who produced some good etchings.

Grignion, Charles. Premium in 1765 for a Drawing; Silver Palette in 1768 for a Drawing. *Portrait and history painter.* Son of Thomas Grignion, the clock-maker. Gold Medallist R.A. 1776. Painted Nelson's portrait. Exhibited at Royal Academy 1770–1784 Died 1804.

Grignion, Thomas. Premium in 1761 for a Drawing. This was the son and successor of Thomas Grignion, one of the earliest members of the Society, an eminent clock-maker, and the donor of the clock now in the meeting-room. Thomas Grignion the younger was also a well-known clock-maker.

Gwilt, George. Silver Palette in 1818 for a Drawing. *Architect.* Best known by his restoration of St. Saviour's Church, Southwark (1822-25). Died 1856.

Habershon, Matthew. Silver Medallion in 1813 for a Design for a Palace. *Architect.* Built several churches, public buildings, and country houses in Derbyshire, Yorkshire, Worcestershire, etc. Exhibited at Royal Academy 1807–1827. Published "Ancient Half-timbered Houses of England," 1836. Died 1852.

Hakewell, John. Premiums in 1759, 1760, 1761, 1762, 1763 and 1764 for Drawings in Various Classes; Silver Palette in 1772 for a Landscape. *Landscape and portrait painter.* Exhibited at Royal Academy 1765–1773. Died 1791.

Hall, John. Premium in 1756 for a Drawing; Premium in 1761 for an Engraving. *Engraver.* Engraved after West, Reynolds, Gainsborough, Hoare, and Dance. "Ranks among our best historical engravers" (Redgrave). Died 1797.

Hamilton, Hugh Douglas. Premiums in 1764, 1765 and 1769 for Historical Picture and Oil Paintings. *Portrait painter.* R.H.A. Died 1806.

Handasyde, Charles. Premiums in 1765 and 1768 for Enamel Paintings. *Miniature and enamel painter.* Exhibited at Royal Academy in 1776.

Harding, James Duffield. Silver Medal in 1815 for a Drawing; Silver Medal in 1818 for an Original Landscape. *Water-colour painter.* Died 1863.

Hardwick, Philip. Gold Medallion in 1809 for Original Drawing of an Academy of Arts. *Architect.* R.A. Amongst his principal works were Euston Square Station, the Goldsmiths' Company's Hall, and Lincoln's Inn Hall and Library. Died 1870.

Hart, Solomon Alexander. Silver Medal in 1862 for a Finished Drawing from a Statue. *Subject painter.* R.A. Exhibited from 1826 to 1880. Librarian of the Royal Academy for some years. He was about twenty when he gained the medal. Died 1881.

Hassell, Edward. Silver Medal in 1828 for an Oil Painting of the Altar-piece of St. Margaret's; Silver Medal in 1829 for Painting of Interior of Edward the Confessor's Chapel. *Landscape painter.* Secretary to Society of British Artists. Most of his exhibits were interiors of Gothic cathedrals. Died about 1852.

Hassell, John. Silver Medal in 1810 for Improvements in Aquatint. *Draughtsman and Engraver.* Worked in aquatint. Published Illustrated Guide to Bath, and some other works.

Hayter, George. Silver Medal in 1821 for an Etching from a picture by Titian. Sir George Hayter, *Portrait and Historical painter.* He was appointed Portrait and History Painter to Queen Victoria on her accession. Died 1871.

Head, Guy. Silver Palettes in 1781 and 1782 for Historical and Landscape Drawings. *Portrait painter.* Resided many years in Rome. "Best known as a copyist" (Redgrave). Died 1800.

Hearne, Thomas. Premiums in 1763 for a Drawing, in 1764 for a Drawing of a Horse, in 1765 for an Etching, in 1767 for a Landscape; Gold Palette in 1776 for a Landscape in Oils. *Water-colour painter.* Worked first as an Engraver. Exhibited at Royal Academy 1765–1806. His drawings for the "Antiquities of Great Britain" were engraved by W. Byrne (q.v.). Died 1817.

Hebert, William. Premium in 1760 for a Flower Picture. *Engraver.* Published some landscapes.

Henderson, John. Premium in 1762 for a Drawing. *Engraver.* Pupil of Shipley. Abandoned his art and became a successful actor. Died 1785.

Henning, John. Silver Medal in 1816 for a Plaster Cast. *Modeller.* Copied some of the Elgin Marbles. Died 1851.

Hilditch, George. Gold Medal in 1823 for an Original Landscape in Oil; Silver Medal in 1824 for a Copy in Oil; Silver Medal in 1825 for an Original Picture (still life) in Oil. *Landscape painter.* Exhibited at Royal Academy 1823–1856. Died 1857.

Hoare, Prince. Premium in 1772 for a Flower Picture. *Portrait and historical painter.* Exhibited at Royal Academy 1781–1815. Son of William Hoare, R.A. Wrote several books on Art. Foreign Corresponding Secretary to Royal Academy. Died 1834.

Hodges, William. Premium in 1759 for Modelling in Clay; Premiums in 1762, 1763, and 1764 for River Views. *Landscape painter.* R.A. Errand-boy in Shipley's School. Appointed in 1772 draughtsman to Captain Cook's second expedition. Died 1797.

Hosted by Google

Hodgson, Thomas. Premium in 1775 for Wood Engraving. *Wood engraver.* Employed by Bewick, and practised on his own account.

Hole, Henry. Gold Palette in 1804 for Wood Engraving. *Wood engraver.* Pupil of Bewick.

Hollis, Thomas. Gold Medal in 1837 for a Water-colour. *Draughtsman.* Son of George Hollis, engraver, and worked with him. Died 1843.

Hook, James Clark. Silver Medals in 1837 and 1838 for Drawings in Chalk; Silver Medal in 1840 for Two Portraits in Oil. *Marine painter.* R.A. Died 1907.

Hopwood, James. Silver Palette in 1803 for an Outline Drawing. *Engraver.* "Designed and engraved some clever book illustrations" (Redgrave).

Horsley, John Callcott. Silver Medal in 1830 for a Chalk Drawing from a Bust; Silver Medal in 1831 for a finished Drawing from a Statue. *Subject painter.* R.A. He painted the portrait of Queen Victoria and her children in the Society's meeting-room. As Horsley was born in 1817 his first award was taken when he was thirteen. Died 1903.

Horwell, Charles. Silver Palette in 1787 for a Figure of Psyche. *Sculptor.* Gold Medallist R.A. 1788. Exhibited at Royal Academy 1787–1807.

Howard, Frank. Silver Palette in 1822 for a Chalk Drawing. *Designer and draughtsman.* Son of Henry Howard, R.A. Exhibited at Royal Academy 1825–1847. Published various works, mostly manuals of instruction in Art. Died 1866.

Hughes, Edwin. Silver Palette in 1846 and Silver Medal in 1847 for Drawings. *Portrait painter.* Died 1908.

Hullmandel, Charles Joseph. Silver Medal in 1819 for Specimens of Lithography. This same year a gold medal was awarded to Senefelder for the invention of lithography. Hullmandel, who was an artist, took up lithography in 1818. From that time he devoted himself to it, and with great success. He introduced many improvements, and was associated with the production of many important works. Died 1850.

Humphreys, William. Premium in 1764 for a Drawing; Premiums in 1765 and 1766 for Mezzotints. *Engraver.* "His mezzotints . . . possess very high merit, and were esteemed among the best of the time" (Redgrave).

Hurlstone, Frederick Yeates. Silver Palette in 1812 for a Drawing; Silver Medals in 1813 and 1814 for Drawings; Silver Medals in 1816 and 1821 for Oil Paintings. *Portrait and history painter.* Exhibited at Royal Academy 1821–1845. Took Gold medal at Paris Exhibition 1855. President of the Society of British Artists. Died 1869.

Hurlstone, Richard. Premiums in 1763 and 1764 for Drawings. *Portrait painter.* Exhibited at Royal Academy 1771–1773. Died about 1774.

Inwood, Henry William. Silver Medal in 1816 for original Architectural Drawing. *Architect.* Joint architect with his father of St. Pancras Church. Exhibited at Royal Academy 1809–1838. Died 1843.

Ireland, Samuel. Premium in 1760 for a Drawing. *Engraver.* Exhibited at Royal Academy in 1782. Published several works. His son, William Henry Ireland, was the author of the famous Shakespearean forgeries. Died 1800.

Jeffereys, James. Gold Palette in 1774 for an Historical Drawing. *Marine painter.* Gold Medallist R.A. 1773. Exhibited at Royal Academy in 1783. Died 1784.

Jones, George. Silver Palettes in 1802, 1804, and 1805 for Drawings. *Battle and subject painter.* R.A. He was supposed to resemble the great Duke of Wellington, and acted the part. Died 1869.

Jones, Thomas. Premiums in 1764 and 1765 for Drawings; Premiums in 1767 and 1768 for Landscapes. *Landscape painter.* Exhibited at Royal Academy 1784–1798.

Jukes, Francis. Premium in 1778 for a "Map of Boston in Aqua Tinta." *Painter and engraver.* "Successful in aquatint, principally sea-pieces and landscapes" (Redgrave). Died 1812.

Keith, Elizabeth. Premium in 1755 for a Drawing. She obtained the second prize in the class between fourteen and seventeen in the Society's first competition. According to Dossie, she died young.

Kelsey, Charles Samuel. Silver Medal in 1846 for a "design for a ticket of admission to the Society's Rooms"; Silver Medal in 1847 for a figure. *Sculptor.* Exhibited at Royal Academy 1840–1877.

Kelsey, Richard. Silver Medal in 1819 for a design for a Mansion; Silver Medallion in 1820 for a design for a National Museum. *Architect.* R.A. Gold Medallist R.A. 1821.

Kendrick, Emma Eleonora. Silver Palette in 1811 for a Drawing; Silver Medal in 1812 for a Miniature; Gold Medals in 1814, 1815, 1816 and 1817 for Miniatures. *Miniature painter.* Daughter of Josephus Kendrick. Exhibited at Royal Academy 1811–1840. Miniature painter to William IV. Died 1871.

Kendrick, Josephus. Silver Medal in 1811 for a Plaster Cast. *Sculptor.* Gold Medallist R.A. 1813. Exhibited at Royal Academy 1813–1829.

Keyse, Thomas. Premium in 1764 for a method of fixing Crayon Drawings. *Painter of still life.* Keeper of Bermondsey Spa. Died 1800.

Kirby, Sarah. Premiums in 1757 and 1758 for Ornamental Designs. Daughter of Joshua Kirby, F.R.S., architect and writer on perspective. Afterwards Mrs. Trimmer, the once popular educational writer.

Hosted by Google

Kirby, William. Premiums in 1760 for an Etching, and in 1761 for a Landscape Drawing. Son of Joshua Kirby, F.R.S. Died 1771.

Kirk, John. Premiums in 1759, 1762, and 1763, for Die Engraving. The 1762 premium (30 guineas) was for "the Seal for the Society's letters, after a design of Cipriani." *Medallist.* Died 1776.

Kirk, Thomas. Silver Palette in 1785 for Historical Drawing. *Painter and engraver.* Exhibited at Royal Academy 1785–1796. "An eminent artist," who "passed like a meteor through the region of art" (Dayes, quoted by Redgrave). Died 1797.

Kitchingman, John. Premiums in 1762, 1763, 1764, 1765 and 1766, and Gold Palette in 1770 for Drawings in various classes. *Miniature painter.* Pupil of Shipley. Exhibited at Royal Academy 1770–1781. Died 1781.

Lambert, James. Premium in 1770 for a Landscape. *Landscape painter.* Exhibited at Royal Academy 1774–1778. A well-known scene-painter and a friend of Hogarth. He was the first President of the Incorporated Society of Artists. Died 1779.

Landseer, Charles. Silver Palette in 1815 for a Drawing of the Laocoon. *Subject painter.* R.A. Brother of Sir Edwin Landseer. Died 1879.

Landseer, Edwin. Silver Palette in 1813 for Drawing of Animals from Life; Silver Medal in 1814 for a Drawing of a Horse; Silver Medal in 1815 for a Painting of a Dog; Silver Medal in 1816 for an original Painting, "The Stable Guardian." As he was born in March 1802 he was only eleven when he received his first award. The eminent and popular *Animal painter*, Sir Edwin Landseer, R.A. Died 1873.

Landseer, George. Silver Medal in 1841 for "Water-colour Drawings of Birds and Beasts from Nature"; Silver Palette in 1842 for an "Oil Painting of a Lion from Nature." *Portrait and landscape painter.* Only son of Thomas Landseer, A.R.A. Was in India from about 1844 to 1870. Died 1878.

Landseer, Miss. Silver Palette in 1813 for an Original Landscape. This was probably Jessica, daughter of John Landseer, R.A. (and sister of Edwin), who "used the painter's brush and the etching-needle," and "etched a few designs after her brother Edwin" (Bryan). Exhibited at Royal Academy 1816 and afterwards. Her younger sister Emma (Mrs. Mackenzie) did not begin to exhibit until 1838.

Landseer, Thomas. Silver Palette in 1810 for an "Etching of Sheep and Goats"; Silver Medal in 1813 for an "Etching of Animals"; Silver Medal in 1814 for a Painting of a Horse. *Engraver.* A.R.A. Eldest brother of Sir Edwin Landseer, many of whose pictures he engraved. Died 1880.

Lane, John Bryant. Silver Palette in 1806 and Gold Medal in 1807 for Historical Drawings. *Historical painter.* Exhibited sacred and classical subjects at Royal Academy 1808–1813. Then went to Rome and devoted fourteen years to the production of what he hoped would be a masterpiece, but proved a failure, "The Vision of Joseph." Afterwards he showed some portraits at the Royal Academy 1831–1834.

Lauranson, William. Premiums in 1760, 1761, 1762, 1763, 1764, 1765 and 1766 for Drawings. *Portrait painter.* Exhibited at Royal Academy 1774–1780.

Lawrence, Thomas. Silver Palette gilt and Five Guineas in 1784 for a Copy of the Transfiguration of Raphael. The committee found that the drawing had not been executed within the limit of time specified, and therefore that it was disqualified, and they consequently withheld the Gold Medal offered. Subsequently they decided to make the above-named award, "as a token of the Society's approbation of his abilities." The award, therefore, does not appear in the printed list. The only record of it is in the Society's minutes, and the committee minutes (Committee of Polite Arts, March 9th and 30th, 1784). The candidate was afterwards Sir Thomas Lawrence, P.R.A. He was not fourteen years of age when the award was made, as he was born in May 1769. Died 1830.

Lawrie, Robert. Premium in 1770 for a Drawing; Premiums in 1773, 1775 and 1776 for Ornamental Designs; Silver Palette in 1773 for a Study of Flowers; Bounty of 30 guineas in 1776 for Improvement in Mezzotint Colour Printing. *Engraver.* Died about 1804.

Leake, Henry. Premium in 1760 for a Drawing. *Portrait painter.* Pupil of W. Hoare, R.A.

Legrew, James. Silver Palette in 1822 for a Plaster Model. *Sculptor.* Pupil of Chantrey. Gold Medallist R.A. 1829. Produced many groups of merit. Died 1857.

Le Jeune, Henry. Silver Palette in 1834 for a Copy of a Figure in Indian Ink. *Historical painter.* A.R.A. Gold Medallist R.A. 1841. Died 1904.

Liart, Matthew. Premiums in 1764 and 1765 for Drawings. Premium in 1766 for an Engraving. *Engraver.* Died about 1782.

Lines, Samuel. Silver Medal in 1825 for Pencil Drawing. *Painter and drawing master.* One of the founders of the Birmingham School of Art. Died 1863.

Linwood, Mary, of Leicester. Silver Medal in 1786 "for submitting to the inspection of the Society, as examples of works of art, and of useful and elegant employment, three pieces of needlework, representing a hare, still life, and a head of King Lear." Miss Linwood opened her celebrated exhibition of embroidered pictures at the Hanover Square Rooms in 1798, and afterwards removed to Leicester Square, where her exhibition was considered one of the chief sights of London. Died 1845.

Hosted by Google

Loat, Samuel. Silver Medal in 1825 and Gold Medal in 1827 for Architectural Designs. *Architect.* Gold Medallist R.A. 1827. Exhibited a design in 1831, "after which there are no traces of his art" (Redgrave).

Lochée, John Charles. Premium in 1775 (30 guineas) for a Statue; Premium in 1776 (50 guineas) for a Statue; Silver Medallion in 1790 for a Bust of the Prince of Wales (afterwards George IV.). An engraving of this bust forms the Frontispiece to Vol. X. of the *Transactions*. *Sculptor.* Exhibited at Royal Academy 1776–1790. Some portrait medallions by him were reproduced by Wedgwood and by Tassie.

Long, J. St. John. Silver Medal in 1825 for a Landscape. Brought up as engraver, but did not follow the profession. Not successful as an artist he set up as a quack doctor. Died 1834.

Lucy, Charles. Silver Medal in 1834 for an Oil Painting. *Historical painter.* Exhibited at Royal Academy 1838–1873. Most of his works related to the History of England, and were meritorious but not very successful.

Lupton, Thomas Goff. Gold Medal in 1822 for a Mezzotint on Soft Steel. He introduced the use of soft steel for mezzotint (see his paper, *Transactions*, Vol. XL. p. 41).* He worked both on steel and on copper, and produced many fine plates after Turner. Died 1873.

Malton, Thomas. Premium in 1774 for a Drawing of a Tide-Mill. *Architectural draughtsman.* Gold Medallist R.A. 1782. Published several topographical works and views. Died 1804.

Malton, William. Premiums in 1775 and 1777 for Drawings of Machines. *Architectural draughtsman.* Brother of Thomas Malton.

Manning, Samuel. Silver Medals in 1831, 1832 and 1838 for Busts; Gold Medal in 1833 for a Model of a Figure; Silver Medal in 1840 for a Group. *Sculptor.* Son of Samuel Manning, also a sculptor. There is some confusion in the books between father and son. According to the account in the "Dictionary of National Biography," which seems the most correct, the "Prometheus," for which the 1833 award was made, was shown in marble at the Royal Academy in 1845. Died 1865.

Marchant, Nathaniel. Premiums in 1761, 1762, 1763, 1764 (two) and 1765 for Engraved Gems. *Gem engraver and medallist.* R.A. Pupil of E. Burch, R.A. Engraver to the Mint. Designed some coins and medals. "Chief of English gem engravers of the eighteenth century" (King, quoted by Forrer). Died 1816.

Marsden, Barbara. Premiums in 1755 and 1756 for Drawings; Premiums in 1757 and 1758 for Ornamental Designs. She married Jeremiah Meyer, R.A. (q.v.). The 1758 award was in a class limited to candidates under fourteen, so she cannot have been twelve years old when she took the prize in 1755.

Martin, David. Premiums in 1759, 1760 and 1761 for Chalk Drawings. *Portrait painter and engraver.* Died 1798.

Martin, William. Gold Palette in 1776 for an Historical Drawing; Premium in 1780 for a Landscape. *History painter.* Pupil of Cipriani. Exhibited at Royal Academy 1775–1816. History painter to George III.

Mason, William. Silver Medal in 1776 for a Drawing of a Horse. *Animal painter.*

Masquerier, John James. Silver Palettes in 1794, 1795 and 1796; Silver Medal in 1799, all for Drawings. *Portrait painter.* Born at Chelsea of French parents. Studied in Paris. Pupil of Vernet. Exhibited at Royal Academy 1796–1838. Painted Napoleon's portrait. Died 1855.

Mayor, Barnaby. Premium in 1765 for a Landscape Etching. *Engraver and painter.* Died 1774.

Medland, Thomas. Silver Palettes in 1777, 1779 and 1780 for Drawings. *Engraver.* Illustrated numerous books. Exhibited at Royal Academy 1777–1822.

Metz, Conrad Martin. Gold Palette in 1783 for an Historical Drawing. A German artist who came to London.

Meyer, Jeremiah. Gold Medal in 1761 for Profile Likeness of George III. from memory, intended to be, but not actually, used in cutting a die for the coinage. Miniature Painter to the king. *Miniature painter.* R.A. Enameller to King George III. and Miniature Painter to Queen Charlotte. Married Barbara Marsden (q.v.), who took several of the Society's prizes. Died 1789.

Milbourn, John. Premiums in 1763, 1764 and 1765 for Drawings. *Portrait painter.* Exhibited at Royal Academy 1773 and 1774.

Millais, John Everett. Silver medals in 1839 for Drawing in Chalk from a Bust; in 1840 for an Historical Composition in Pencil; in 1841 for an Historical Composition in Sepia; Gold Medal in 1846 for an Original Historical Painting; Gold Medallion in 1847 for an Original Composition in Oil. *Subject, landscape and portrait painter.* Sir John Everett Millais, Bart., P.R.A. As Sir John Millais was born in 1829, his first award was obtained when he was only ten. Died 1896.

Miller, John. Premiums in 1764 for a Flower Picture; and in 1766 for an Engraving. *Flower painter and Engraver.* Published an illustrated botanical work, 1770–7.

* The credit of having produced the first mezzotint on steel has always been given to William Say, the mezzotint engraver, and it would appear with justice, since there is a mezzotint print by him, after a portrait of Princess Charlotte (daughter of George IV.) by G. Dawe, R.A., in the British Museum. The print was published by Dawe in 1817, and is said to be from a steel plate. The two inventors were probably working independently. There is nothing in Lupton's paper to suggest that his work was not original, and probably it was.

Mills, George. Gold Medals in 1817 and 1818 for Medal Dies, and in 1823 for presenting the Society with a new Die for the Vulcan Medal. *Medallist.* Produced medals of General Moore, Watt, West, George IV., and Sir F. Chantrey. Exhibited at Royal Academy 1816–1823. Died 1824.

Mitchell, Thomas. Premium in 1766 for a Sea-piece. *Marine painter.* Exhibited at Royal Academy 1774–1789. Had appointments in the dockyards, and worked as an amateur.

Moore, Francis John. Premium in 1766 for an Allegorical Bas-relief; Silver Palette in 1769 for a Statue. *Sculptor.* Died 1809.

More, Samuel. Premiums in 1763 and 1764 for two sets of Impressions of Pastes resembling Antique Cameos and Intaglios. Afterwards Secretary of the Society.

Moring, Thomas. Gold Medal in 1845 for "an Engraving on White Cornelian." *Seal engraver.* Practised as a professional seal engraver and medallist. Died 1884.

Mortimer, John Hamilton. Premiums in 1759 (two), 1760, 1761 and 1762; Premium in 1763 (50 guineas) for an Oil Painting of Edward the Confessor taking his Mother's Treasures; Premium in 1764 (100 guineas) for St. Paul Preaching to the Britons. The last picture was placed as an altar-piece in the church of High Wycombe, Bucks, where the painter is buried. *History painter.* A.R.A. Died 1779.

Moser, George Michael. Premium in 1758 for "A Model, chased in gold, of an Honorary Medal proposed by him to the Society . . . afterwards engraved by John Kirk" (Dossie). *Enameller and modeller.* R.A. One of the founders of the Royal Academy, and its first Keeper. "Had high merits as an artist, excelling not only as a chaser, but as a medallist, and he painted in enamel with great beauty and taste" (Redgrave).

Moser, Joseph. Premiums in 1762, 1763 and 1765 for Modelling in Wax. *Enameller.* Nephew of G. M. Moser, R.A. Exhibited at Royal Academy 1774–1787. Afterwards a London Police Magistrate.

Moser, Mary. Premium in 1758 for an Ornamental Design; Premium and Silver Medal in 1759 for a Flower Picture. The Silver Medal was a special and additional award "presented to her as a further Reward for her extraordinary merit." *Flower painter.* R.A. Daughter of G. M. Moser, R.A. Original member of Royal Academy, and one of the two woman Academicians (the other being Angelica Kauffman). Married Captain Hugh Lloyd. Died 1819.

Moses, Henry. Silver Palettes in 1800 and 1801 for Drawings. *Engraver.* Produced plates after Barry, Northcote, Opie, and others. Died 1870.

Mulready, William. Silver Palette in 1801 for a Drawing. *Subject painter.* R.A. Mulready was born in 1786, so he was only fourteen at the date of the award. In 1848 a collection of Mulready's works was exhibited in the Society's house. Died 1863.

Nesbitt, Charlton. Silver Palette in 1798, and Silver Medal in 1802, for Wood Engraving. *Wood engraver.* A pupil of Bewick. Successful illustrator of numerous books. Died 1838.

Netherclift, Joseph. Premium in 1829 for Lithographic Transfer Paper. *Lithographer and printer.* This was the first practical transfer paper, for though the earliest lithographs made were transfers, the difficulties attending the process were so great that the work was all executed direct on the stone until a suitable paper was produced. Died 1863.

Nollekens, Joseph. Premium in 1759, at the age of eighteen, for a Drawing; Premiums in 1759, 1760, 1761 (two) and 1762 for Bas-reliefs. *Sculptor.* R.A. This celebrated sculptor amassed a large fortune by his work. His peculiarities are well known from the Life by Smith, "Nollekens and His Times." Died 1823.

Norton, Christopher. Premium in 1760 for a Drawing. *Engraver.*

Okey, Samuel. Premiums in 1765 and 1767 for Mezzotints. *Engraver.* Engraved after Sir J. Reynolds, Pine, and others.

Pain, George Richard. Gold Medal in 1812 for a Design for a Church; Silver Medal in 1813 for a Design for a Palace. *Architect.* Apprenticed to Nash. Went to Ireland about 1817, and practised there. Died 1838.

Papworth, Edgar George. Silver Medal in 1825 for a Pencil Drawing; Silver Palette in 1827 for a Bas-relief. *Sculptor.* Died 1866.

Papworth, John Woody. Silver Medal in 1838, Gold Medal in 1840, and Gold Medallion in 1845 for Architectural Designs. *Architect and heraldic painter.* Designed for glass, pottery, and textiles. Brother of Wyatt Papworth. Died 1870.

Papworth, Wyatt. Silver Medal in 1836, and Silver Palette in 1838 for Architectural Drawings. *Architect.* Editor of the "Dictionary of Architecture." Curator of Soane Museum. Died 1894.

Parke, Henry. Silver Medals in 1807, 1808, 1810, 1811, 1812; and Gold Medal in 1814 for sea-pieces. *Architect.* Pupil of Sir John Soane. Made many drawings of monuments of Italy and Egypt, and, according to Redgrave, "Some naval drawings of much ability." A collection of his drawings is preserved by the R.I.B.A. Died 1835.

Parker, John. Premiums in 1762 and 1763 (two in each year) for Drawings in different classes. *Landscape painter.* Exhibited at Royal Academy 1770–1778.

Parry, William. Premiums in 1760, 1761, 1762, 1763, 1764 and 1766 for Drawings in various classes. *Portrait painter.* A.R.A. Died 1791.

Pars, Albert. Premiums in 1759, 1764 and 1765 for Modelling in Wax; Premium in 1767 for a Bronze Cast. *Modeller.* Brother of William Pars, A.R.A. "Successful modeller in wax" (Redgrave).

Hosted by Google

Pars, Anne. Premiums in 1764, 1765, and 1766 for Drawings. Sister of William Pars, A.R.A. Exhibited at Royal Academy in 1786.

Pars, William. Thirteen Premiums from 1756 to 1764 in various classes, including Drawings of Landscapes, Animals, Still Life, and Ornamental Design, Wax Modelling, and an Oil Painting. In 1757 he was admitted to the class under fourteen, so he cannot have been thirteen when he took his first award. *Portrait painter.* A.R.A. Produced also Views of Temples in Greece and in Asia Minor, and some Swiss views. Brother of Henry Pars, Shipley's successor as the Master of the Academy in the Strand. Died 1782.

Parsons, William. Premiums in 1757, 1758 and 1760 for Drawings. *Portrait painter (amateur).* Died 1795.

Patmore, Coventry. Silver Palette in 1838 for a Pencil Drawing. The well-known poet. He contributed to the *Germ*, and was a friend of the first pre-Raphaelites, but does not appear to have continued his artistic studies or work. Died 1896.

Patten, George. Silver Palette in 1816 for a Miniature. *Portrait and history painter.* A.R.A. Exhibited at Royal Academy, 1819 to about 1865. Portrait painter in ordinary to Prince Albert. Died 1865.

Pearson, Mrs. C. Silver Palette in 1816; Silver Medal in 1817; Gold Medal in 1819 for Oil Paintings. *Portrait painter.* Exhibited at Royal Academy 1821–1842. Her maiden name was Dutton, and the first two awards were gained before her marriage. Died 1871.

Peart, Charles. Silver Medallion in 1783 for Modelling from the Life. *Sculptor.* Gold Medallist R.A. in 1782. Exhibited at Royal Academy 1778–1797.

Peters, Matthew William. Two Premiums in 1759 for Drawings. *Portrait and history painter.* R.A. Became a clergyman and abandoned painting, except as an amateur. Died 1814.

Pether, William. Premiums in 1756 for a Drawing, and for an Ornamental Design; in 1760 and 1767 for Mezzotints. *Mezzotint engraver.* Exhibited miniatures at Royal Academy 1781 to 1794, but "his true art was mezzotint," in which he "gained great distinction" (Redgrave). Died about 1794.

Physick, Edward Gustavus. Silver Medals in 1823 and 1824; Gold Medal in 1826 for Plaster Models. *Sculptor.* Exhibited at Royal Academy and elsewhere 1822–1868.

Physick, E. J. Silver Medal in 1846 for a Plaster Cast. Silver Medal in 1847 for a modelled figure. *Sculptor.*

Pinches, Thomas R. Silver Medals in 1836 and 1837 for Medal Dies. *Medallist.* One of the well-known family of London die-sinkers and medallists. "Cut many military, academical, and private medals" (Forrer). Amongst them was a memorial medal of the Duke of Wellington 1852.

Pine, Robert Edge. Premium in 1760 (100 guineas) for an Oil Painting, "The Surrender of Calais"; Premium (100 guineas) in 1763 for "Canute Rebuking his Courtiers." *History and portrait painter.* Exhibited at Royal Academy 1760–1784. Went to America. Died at Philadelphia 1790.

Pingo, Benjamin. Premiums in 1765, 1766 and 1769 for Drawings. Youngest son of Thomas Pingo.

Pingo, Henry. Premiums in 1756, 1758, 1759, 1760 and 1761 for Ornamental Designs. Second son of Thomas Pingo. Exhibited flower pictures at Free Society of Artists, 1772 and 1773.

Pingo, John. Premiums in 1759, 1760, 1762, 1763 and 1765 for Die Engraving. *Medallist.* Chief Engraver to the Mint. Eldest son of Thomas Pingo. Died 1830.

Pingo, Lewis. Premiums in 1756 and 1759 for Drawings; Premiums in 1759 and 1760 for Medallions; Premiums in 1757, 1758, 1760 and 1761 for Ornamental Designs; Premiums in 1761, 1763 and 1764 for Die Engraving; Premium in 1763 for Gem Engraving; Gilt Palette in 1770, Gold Palettes in 1771 and 1772 for Medallions. *Medallist.* Third son of Thomas Pingo. Engraver to the Mint. Died 1830.

Pingo, Mary. Premiums in 1758 and 1759 for Ornamental Designs; in 1761 and 1762 for Drawings of Flowers. Daughter of Thomas Pingo.

Pingo, Thomas, Paid 80 guineas in 1758 for making the dies for the Society's First Medal from a design by James Stuart, the Architect "Athenian Stuart." *Medallist.* Engraver to the Mint. Died 1776.

Pitts, William. Gold Medal in 1812 for a Wax Model. *Sculptor.* Exhibited at Royal Academy 1823–1839. Produced much successful work. Died 1840.

Pocock, William Fuller. Silver Medallion in 1807 for an Architectural Design. *Architect.* Exhibited at Royal Academy 1799–1827.

Porter, John Ashwood. Premium in 1755 for a Pen-and-Ink Drawing. He was the last of the five candidates who took the first prizes offered by the Society for young people under fourteen. He was the son of a drawing master in Wapping (Dossie), but nothing more seems to be known about him.

Porter, Robert Ker. Silver Palette in 1793 for an Historical Drawing. *History painter.* Sir Robert Porter, brother of Anne and Jane Porter, the novelists. "He was by turns, during his adventurous career, artist, soldier, author, and diplomatist" (Redgrave). Died 1842.

Poynter, Ambrose. Silver Medallion in 1818 for an Architectural Design. *Architect.* Father of Sir Edward Poynter, P.R.A. Exhibited at Royal

Hosted by Google

Academy 1817-1852. Foundation Member of R.I.B.A., and its Secretary 1840, etc. Took important part in establishment of Schools of Design. "Had considerable practice as an architect" ("Dictionary of National Biography"). Died 1886.

Proctor, Thomas. Gold Palette in 1787 for an Historical Drawing. *Sculptor and History painter.* A brilliant but unfortunate genius. Gold Medallist R.A. 1784. Exhibited at Royal Academy 1785-1794. Died in misery and want 1794.

Pugh, Hubert. Premium in 1765 for a Landscape in Oil. *Landscape painter.* "There is a work of his in the Lock Hospital" (Redgrave). Died after 1788.

Pye, Charles. Silver Palette in 1791 for a Drawing. *Engraver.*

Radclyffe, George Edward. Silver Medal in 1824 for an Etching. Silver Palette in 1826 for an Engraving. *Engraver.* Worked for the Annuals and *Art Journal.* Died 1863.

Raimbach, Abraham. Gold Palette in 1806 for Wood Engraving. *Engraver.* Exhibited miniatures at Royal Academy 1797-1805, but afterwards devoted himself to engraving. Engraved many of Wilkie's pictures. Died 1843.

Ranson, Thomas Frazer. Silver Medal in 1814; Gold Medals in 1821 and 1822 for Engraving. *Engraver.* He was interested in the question of preventing the forgery of bank-notes, and barely escaped conviction for having a forged note in his possession.

Ravenet, Francois Simon. Premiums in 1761, 1762 and 1764 for Engravings. *Engraver.* A.R.A. Native of France. Came to England about 1750. Worked for Hogarth and Boydell. Engraved the "Mariage à la Mode." Died 1774.

Read, Nicholas. Premiums in 1762 (100 guineas) and in 1764 (140 guineas) for Statues. *Sculptor.* Pupil of Roubiliac, and his successor. Some monuments by him are in Westminster Abbey. Died 1787.

Read, Richard. Silver Palette in 1771 for a Drawing. *Engraver.* Worked chiefly in mezzotint.

Reinagle, Philip. Premium in 1767 for a Drawing. *Animal and landscape painter.* R.A. "His hunting pieces, sporting dogs, and dead game were excellent" (Redgrave). Died 1833.

Revel, Richard. Premium in 1755 for a Chalk Drawing of a Horse. This was the fifth prize in the class between fourteen and seventeen in the Society's first competition. Nothing seems to be known of his after career (Dossie).

Richardson, George. Premium in 1765 for an Architectural Drawing. *Architect.* Author of the "New Vitruvius Britannicus" and other works on architecture.

Rigaud, Stephen Francis. Silver Palette in 1794; Gold Palette in 1799 for Drawings. *Water-colour painter.* Exhibited at Royal Academy 1797-1815.

Roberts, James. Premium in 1766 for a Drawing. *Portrait painter.* Exhibited at Royal Academy 1773-1799.

Robertson, George. Premiums in 1760 and 1761 (three) for Drawings. *Landscape painter.* Pupil of Shipley. Went to Jamaica and painted views of the island, which were exhibited in London and engraved. Died 1788.

Rochard, Frederick. Silver medal in 1823 for a Water-colour Portrait. *Miniature painter.* Exhibited at Royal Academy from 1819. Died 1858.

Rogers, Philip Hutchins. Silver Medal in 1808 and Gold Medal in 1811 for Oil Paintings. *Marine and landscape painter.* Occasional Exhibitor at Royal Academy up to 1835. Died 1853.

Rolls, Charles. Silver Medal in 1818 for a Drawing. *Engraver and draughtsman.* Assisted the Findens in their "Gallery of British Art."

Romney, George. Premium in 1763 (20 guineas) for an Oil Painting of the Death of General Wolfe; Premium in 1765 (50 guineas) for Oil Painting of the Death of Edward the First. The celebrated *Portrait painter.* Died 1802.

Romney, John. Silver Palette in 1806 for Outline Drawing. *Engraver and draughtsman.* Engraved some of Smirke's illustrations to Shakespeare, etc. Died 1863.

Rooker, Michael Angelo. Premiums in 1759 for a Drawing (age under fourteen) and in 1760 for a Landscape. *Water-colour painter and engraver.* A.R.A. Died 1801.

Ross, William. Silver Palette in 1807 for a Drawing (at the age of twelve); Silver Medal in 1808 for a Drawing; Silver Palette in 1809 for a Miniature; Silver Medals in 1810 and 1811 for Drawings; Silver Palette in 1813 for a Drawing; Gold Medal in 1816 for a Portrait of the Duke of Norfolk; Gold Medal in 1817 for an Historical Painting. Sir William Ross, R.A., the well-known *Miniature painter.* He was Chairman of the Committee of Fine Arts 1845-6, and a Member of the first Council 1845 and 1846. An exhibition of his works was held by the Society in 1860. Died 1860.

Rossi, Charles. Premium in 1794 (50 guineas) for a Group of Statuary. *Sculptor.* R.A. Sculptor to George IV. and to William IV. Executed several monuments in St. Paul's Cathedral. Died 1839.

Rossi, Henry. Silver Medal in 1815 for copy of Plaster Cast. *Sculptor.* Designed terra-cotta ornaments for interior of St. Pancras Church.

Russell, John. Premiums in 1759 and 1760 for Drawings. *Portrait painter.* R.A. His best work was in crayons, and he published a book on "Painting with Crayons." Died 1806.

Hosted by Google

Ryder, Thomas. Premium in 1766 for a Drawing; Gold Medal in 1803 for a Line Engraving. *Engraver and draughtsman.* "One of the best engravers of his time" (Redgrave). Executed eight plates for Boydell's Shakespeare Gallery. Died 1810.

Ryley, Charles Reuben. Premium in 1770 for a Drawing. *History painter.* Gold Medallist R.A. 1778. Exhibited at Royal Academy 1780–1798. Died 1798.

Samuel, George. Silver Medallion in 1784 for a View of the Front of the Society's House. *Landscape painter.* Exhibited at Royal Academy 1786–1823.

Samuel, Richard. Premium in 1773 for a Tool for Laying Mezzotint Grounds; Gold Palettes in 1777 and 1779 for Drawings. *Portrait Painter.* Exhibited at Royal Academy 1772–1779.

Sass, Henry. Silver Medal in 1807 for an Outline of the Laocoon. *Portrait painter and teacher.* According to Redgrave he was more successful in the latter capacity than in the first. Exhibited at Royal Academy 1808–1838. Died 1844.

Savage, William. Silver Medal in 1825 for "Block Printing in Colours in Imitation of Drawings." *Painter and engraver.* Experimented in printing in colour from wood blocks, and published a book on the subject in 1822.

Say, Frederick Richard. Silver Palette in 1817 for a Drawing; Silver Medal in 1819 for a Chalk Drawing; Silver Medal in 1820 for Crayon Drawings. *Portrait painter.* Exhibited at Royal Academy from 1825. Died probably about 1860.

Scharf, George. Silver Palette in 1835, and Silver Medal in 1836 for Drawings. Sir George Scharf, K.C.B., Keeper of the National Portrait Gallery. Died 1895.

Scheemakers, Thomas. Premiums in 1765 for Modelling in Clay, and in 1766 for a Bas-relief. *Sculptor.* Son of Peter Scheemakers, a Belgian sculptor who settled in London. Exhibited at Royal Academy 1765–1804. Died 1808.

Schiavonetti, Lewis. Silver Medal in 1807 for Engraving of the British Troops in the Bay of Aboukir. *Engraver.* Pupil of Bartolozzi. Died 1810.

Scott, John. Gold Medal in 1811 for two Original Engravings of Fox Hunting. *Engraver.* Successful as an engraver of animals. Died 1828.

Scoular, James. Premium in 1755 for a Drawing (at age of fourteen). *Miniature painter.* Exhibited at Royal Academy 1761–1787.

Scoular, William. Silver Medals in 1816 and 1819; Gold Medal in 1820; all for models. *Sculptor.* Gold Medallist R.A. 1817. Exhibited at Royal Academy 1815–1846.

Scriven, Edward. Gold Medal in 1813 for an Engraving of Gerard Douw; Gold Medal in 1815 for Engravings, after West. *Engraver.* Worked for Dilettanti Society, Shakespeare Gallery, etc., and was much employed by publishers. Died 1841.

Seddon, Thomas. Silver Medal in 1848 for Drawings of an Original Design for an Ornamental Carved Sideboard. He was the son of a cabinet maker. *Landscape painter.* Exhibited at Royal Academy 1852–1856. Died 1856. A collection of his works was shown at the Society in 1857, when an address was delivered by John Ruskin (*Journal*, Vol. V. p. 360).

Senefelder, Aloys. Gold Medal in 1819 for the Invention of Lithography. The process had been perfected in 1798, and lithographs had been published in England in 1801, but in 1818 Senefelder published his book on the subject.

Setchel, Sarah. Silver Palette in 1829 for a Pencil Drawing. *Water-colour painter.* Exhibited at Royal Academy 1831–1867. Gained great popularity by her picture, "The Momentous Question," engravings of which were hung in every print-shop. Died 1894.

Sharp, William. Premium in 1760 for a Drawing; Premiums in 1761, 1763 and 1764 for Designs. *Engraver.* "One of the most celebrated of English line engravers" (Bryan). Engraved West's portrait of Samuel More, the Society's Secretary. Died 1824.

Shelley, Samuel. Silver Palette in 1770 for a Figure Drawing. *Miniature Painter.* Exhibited at Royal Academy 1773–1808. Died 1808.

Shenton, Henry Chawner. Silver Medal in 1844 for a Clay Model of Sabina. *Sculptor.* Son of the engraver of the same name. Died 1846.

Sherlock, William. Premium in 1759 for a Figure Drawing; Premium in 1760 for an Engraving. *Portrait painter and engraver.* Exhibited at Royal Academy 1802–1806. Engraved portrait heads for Smollett's "History of England."

Sherwin, John Keyse. Silver Palette in 1769 for a Drawing; Premium in 1772 (50 guineas) for a Drawing; Premium in 1774 for an Engraving; Premium in 1775 for an Engraving; Gold Medal in 1778 for "Excellence in Engraving." The engraving (reproduced on page 732) for which the 1774 Premium was awarded was used for a vignette on the titlepage of the "Register of Premiums and Bounties" issued in 1778, and was reprinted as a frontispiece to the first volume of the *Transactions.* *Engraver and history painter.* Worked under Bartolozzi. Gold Medallist R.A. 1772 (for a Painting). "It is as an engraver that he will rank high among our artists" (Redgrave). Engraver to George III. Died 1790.

Sievier, Robert William. Silver Medal in 1812 for a Pen-and-Ink Drawing. *Engraver and sculptor.* After practising as an engraver for some years he devoted himself to sculpture. A man of varied accomplishments and of scientific tastes, he became an F.R.S. Died 1865.

Hosted by Google

Simmons, William Henry. Silver Medal in 1833 for an Engraving. *Engraver.* "For many years perhaps the chief of English workers in his own line" (Bryan). Engraved after Landseer, Millais, Faed, Holman Hunt, Frith, Rosa Bonheur, and Hook. Died 1882.

Simpson, Philip. Silver Medal in 1822 for a Copy of a Portrait; Gold Medal in 1823 for a Portrait. *Portrait and subject painter.* Exhibited at the Royal Academy up to 1836.

Skelton, William. Silver Palettes in 1778 and 1779 for Drawings. *Engraver.* Published various works, including series of portraits of the family of George III. Died 1848.

Smart, John. Premiums in 1755 and 1756 (aged twelve) for Drawings; Premium in 1757 for a Portrait in Chalks of Shipley; Premium in 1758 for a Drawing. *Miniaturist.* Exhibited at Royal Academy 1770–1811. Spent some years in India. Died 1811.

Smirke, Robert. Silver Medallion in 1797 for Drawing of the Water-gate at York Buildings. Sir Robert Smirke. *Architect.* R.A. Died 1867.

Smith, Emma. Silver Palette in 1803 for an Historical Drawing. *Water-colour painter.* Exhibited at Royal Academy in 1805. She was a granddaughter of "Smith of Derby."

Smith, George. Premiums in 1760, 1761 and 1763 (50 guineas each) for Landscapes in Oil. *Landscape painter.* Known as "Smith of Chichester." "In his day they [his works] were lauded beyond their merits" (Redgrave), and he acquired considerable reputation and popularity. Died 1776.

Smith, Joachim. Premium in 1758 for a Medallion Model in Wax; Premium in 1761 for a Composition for Modelling Portraits in Miniature. *Modeller.* Dossie says that he practised his invention successfully for some years. Some of his models were reproduced by Wedgwood and by Tassie.

Smith, John. Premiums in 1760 and 1761 (25 guineas each); Premium in 1762 (50 guineas) for Landscapes in Oil. *Landscape painter.* Younger brother of George Smith, and not so good a painter. Died 1764.

Smith, J. Catterson. Silver Medal in 1825 for an Oil Painting. *Portrait painter.* President of the Royal Hibernian Academy. Died 1872.

Smith, Nathaniel. Premiums in 1758, 1761 and 1762 for Modelling Figures in Clay; Premiums in 1859 (two) for Drawings; Premium in 1760 for a Bas-relief. *Modeller.* Pupil of Roubiliac. Assistant to Nollekens.

Smith, Thomas. Premium in 1760 for an Engraved Gem. *Seal engraver.* No record of any later work of his has been found.

Solomon, Abraham. Silver Medal in 1838 for a Chalk Drawing from a Statue. *Subject painter.* Exhibited at Royal Academy 1843–1862. Died 1862.

Spang, Michael Henry. Premium in 1758 (30 guineas) for Modelling the "Seal of the Society used for Letters" designed by Cipriani and engraved by Kirk. *Modeller.* Carved the decorations on the Admiralty Screen, and the figures on the pediment of Spencer House. Died about 1767.

Spicer, Nehemiah. Premiums in 1762, 1763 and 1764; and a Gilt Palette in 1768 for Gem Engraving. No further record of his work has been found.

Spiller, John. Silver Palettes in 1778 and 1780 for Outline Drawings. *Sculptor.* Exhibited at Royal Academy 1778–1792. "The statue of King Charles, which stood in the centre of the piazza of the Royal Exchange, before the fire in 1838, was his work" (Redgrave). Died in 1794.

Spilsbury, John. Premiums in 1761, 1762 and 1763 for Mezzotints. *Mezzotint Engraver.* Engraved some of Reynolds's portraits. Drawing-master at Harrow about 1782.

Stannard, Mrs. Joseph. Gold Medal in 1828 for an Oil Painting. Wife of Joseph Stannard, a well-known landscape and marine painter of Norwich. Some members of the Stannard family designed for the Lowestoft Pottery works.

Staples, Robert. Premiums in 1763, 1764, 1765 and 1766 for Gem Engraving. He was a jeweller in Harp Court, Fleet Street. Nothing more seems to be known of his work.

Stevens, Edward. Premiums in 1762 and 1763 for Architectural Designs. *Architect.*. A.R.A. Pupil of Sir William Chambers. Died 1775.

Strange, Mary Bruce. Premiums in 1764 and 1765 for Drawings. Daughter of Sir Robert Strange, the eminent engraver.

Stubbs, James Henry Phillipson. Silver Medal in 1826 for an Etching; Silver Palette in 1828 for a Pen-and-Ink Drawing. *Engraver.* Pupil of the Findens. Produced book illustrations and some sporting plates. Died 1864.

Swaine, Francis. Premium in 1764 for a Sea-Piece. *Marine painter.* Two small paintings by him are at Hampton Court (Redgrave). Died 1782.

Swaine, John Barak. Silver Palette in 1831 for a Chalk Drawing; Silver Medal in 1833 for an Etching. Redgrave, under John Swaine, the father of J. B. Swaine, says he died in 1828, and Bryan follows him, but this seems to be a mistake. A John Barak Swaine exhibited in 1837 at the B. I.

Tallmache, William. Silver Medal in 1813 for a Bronze Cast. *Sculptor.* Gold Medallist R.A. 1805. "He does not appear to have followed up this success" (Redgrave).

Tassie, James. Premium in 1767 for "Figures, Heads, and Portraits of his composition resembling antique onyx." *Gem engraver.* Exhibited at

Royal Academy 1769-1791. Successful in reproduction of ancient engraved gems, and produced many fine originals. Died 1799.

Taylor, Isaac. Gold Palette (and 25 guineas) in 1791 for an Engraving of Opie's "Death of Rizzio." *Engraver*. Pupil of Bartolozzi. "Known chiefly by his works for Boydell's Shakespeare Gallery" (Redgrave). Died 1829.

Taylor, John. Premiums in 1761 and 1762 (two) for Drawings. *Portrait and subject painter*. Exhibited at Royal Academy 1779-1800. Died 1838.

Taylor, John. Premiums in 1763 and 1764 for Designs for Medals. Jeweller at Bath (Dossie).

Taylor, Simon. Premiums for Drawings in 1756, 1757, 1758 and 1759; Premiums in 1759 and 1761 for Pictures of Flowers; Premium in 1759 for an Etching. *Botanical draughtsman*. Pupil of Shipley. Employed by Lord Bute and by Dr. Fothergill. Died about 1798.

Theed, William. Silver Palette in 1820 and Silver Medal in 1822 for Copies of Statues. *Sculptor*. R.A. Settled in America, where he died 1850. The bust of the Prince Consort in the possession of the Society is the work of his son, also William Theed.

Tomkins, Charles. Silver Palette in 1776 for a View of Millbank. *Painter and engraver*. Son of William Tomkins, A.R.A. Exhibited at Royal Academy 1773-1779.

Tomkins, Peltro William. Silver Palette in 1780 for Landscape Drawing. Gold Medal in 1813 for method of refining ox-gall for artistic purposes. *Engraver*. Son of William Tomkins, A.R.A. Published various works, original and after other artists. Engraver to Queen Charlotte. Died 1840.

Tomkins, William. Premium in 1762 for a Landscape. *Landscape painter*. A.R.A. Also painted some pictures of dead game. Died 1792.

Toussaint, Auguste. Premium in 1766 and Silver Palette in 1768 for Drawings. *Miniature painter*. Exhibited at Royal Academy 1775-1788.

Towne, Francis. Premium in 1759 for a Design. *Landscape painter*. Exhibited at Royal Academy 1775-1810. Died 1816.

Towne, Joseph. Silver Medal in 1826 for a Model of a Skeleton; Gold Medal in 1827 for a Wax Model of the Brain. The skeleton is now in the museum of Guy's Hospital. He was seventeen when he constructed it, and it served as an introduction to Sir Astley Cooper, who at once put Towne in the way of obtaining employment. *Anatomical modeller*. Though self-taught, he was soon "engaged continuously in the practice of the art which he originated and brought to perfection, though it died with him" (D'Arcy Power, in the "Dictionary of National Biography"). He made over a thousand wax models of anatomical preparations, remarkable both for their verisimilitude, and for their artistic qualities. Towne was also a capable sculptor. Died 1879.

Turner, William. Silver Palette in 1793 for a Landscape Drawing. This may have been "Turner of Oxford," who exhibited as a water-colour landscape painter at Royal Academy, etc., for fifty-four years (Bryan), and died 1862.

Turnerelli, Edward. Silver Medal in 1833 for a Drawing. Son of Peter Turnerelli, a sculptor of reputation. Studied at Royal Academy. Achieved notoriety by collecting money for a gold laurel wreath for the Earl of Beaconsfield, which Lord Beaconsfield refused. Died 1890.

Twining, Elizabeth. Silver Medal in 1824 for a Water-colour painting of Flowers. *Amateur painter*. Philanthropist and Botanist. Daughter of Richard Twining. One of the Founders of Bedford College. Died 1889.

Tytler, George. Silver Medal in 1825 for a Lithographic Drawing. *Lithographer*. Published some views of Italian Scenery. Died 1859.

Underwood, Thomas. Silver Palette in 1828 for a Pencil Drawing of a Landscape. *Engraver and Writer on art and archæology*. Lived in Birmingham. Died 1882.

Vacher, Charles. Silver Medal in 1837 for a Lithograph. *Water-colour painter*. Died 1883.

Van Rymsdyk, Andries. Premiums in 1765 (at the age of eleven), 1766 and 1767 for Drawings; Premium in 1767 for a Mezzotint. Son of John van Rymsdyk, History painter.

Vendramini, Caroline. Silver Medal in 1821 for a Drawing. Daughter of Giovanni Vendramini.

Vendramini, Giovanni. Gold Medals in 1819 and 1829 for Engravings. *Engraver*. His reputation rested chiefly on his reproductions of the Old Masters. Died 1839.

Vendramini, R. Silver Palette in 1829; Silver Medals in 1830 and 1833 for Drawings. Daughter of Giovanni Vendramini. It is uncertain to which of the two sisters the 1829 and 1830 awards were made.

Vickers, Alfred Gomersal. Gold Medal in 1828 for a Marine Painting. *Marine, subject and landscape painter*. Exhibited at Royal Academy and elsewhere 1827-1837. Died 1837.

Vivares, Mary. Premiums in 1759 and 1761 for Drawings; Premium in 1763 for an Engraving. Daughter of Francis Vivares, the engraver.

Vivares, Thomas. Premiums in 1758 for an Ornamental Design; in 1760 for an Etching; in 1761 for a Drawing; in 1762 for an Etching; in 1763 for a Landscape; in 1764 and 1765 for Engravings; in 1766 for an Etching. *Engraver*. Son of Francis Vivares, the well-known engraver. Exhibited at Royal Academy 1783-1787.

Vulliamy, Benjamin. Premium in 1758 for a Drawing. He was a son of Justin Vulliamy, and the father of Benjamin (the second) and Lewis Vulliamy. Justin and the two Benjamins were eminent clock-makers. Benjamin the elder was

Hosted by Google

favoured and consulted by George III. in connection with Kew Observatory, which was a hobby of the King. Died about 1820.

Vulliamy, Lewis. Silver Medal in 1813 for an Architectural Design. *Architect.* Gold Medallist, R.A. 1813. Exhibited at Royal Academy 1822–1838. Son of Benjamin Vulliamy the elder. Architect of many public buildings in London, and of numerous mansions, including Dorchester House, Park Lane. Died 1871.

Ward, Edward Matthew. Silver Palette in 1831 for "a copy in Indian ink of figures." *Historical painter.* R.A. From 1839, when he first exhibited at Royal Academy, his work was popular and successful. Painted several of the pictures in the corridor of the House of Commons. Died 1879.

Ward, Francis Swaine. Premium in 1765 for a Sea-piece. *Landscape painter.* Entered the service of the H.E.I.C. and went to Calcutta. Made numerous drawings of Indian temples, etc. Died about 1805.

Ward, John Raphael. Silver Medal in 1823 for a Water-colour Portrait (copy). *Engraver and copyist.* Produced miniature copies of some of Sir Thomas Lawrence's portraits. Son of James Ward, R.A. His daughter married E. M. Ward, R.A. Died 1879.

Ward, William. Silver Palette in 1805 for a Drawing of Ewell Church. *Mezzotint engraver.* A.R.A. Engraved many of the pictures of George Morland, whose sister he married. Died 1826.

Ward, William James. Silver Medals in 1813, 1814 and 1815 for Drawings. *Mezzotint engraver.* Son of William Ward, A.R.A. Engraver to the Duke of Clarence, afterwards William IV. Died 1840.

Waring, John B. Silver Medal in 1843 for an Architectural Design. *Architect.* Superintendent at 1862 Exhibition. Author of the three volumes on the Industrial Art and Sculpture of the Exhibition, and of other works on Art. Died 1875.

Warner, William. Gold Medal in 1827 for an Intaglio. *Seal engraver.* Started a business in London, which is still carried on by his son. Engraved seals for Queen Victoria. Died 1872.

Warren, Charles. Gold Medal in 1823 for Improvements in the Art of Engraving on Steel. *Engraver.* He had been employed in engraving for calico printing. Came to London in 1802 and was successful in book illustration. Chairman of Committee of Polite Arts, 1822. Died 1823.

Watson, John Burgess. Gold Medal in 1824 for a Design for a House; Silver Medal same year for a Drawing of a Crane. *Architect.* Died 1847.

Webber, Henry. Silver Palette in 1783 for an Historical Drawing. Gold Medallist R.A. in 1779 for a Group. As his address was "Etruria," he was presumably employed by Wedgwood.

Westall, William. Silver Palettes in 1798 for a Drawing; and in 1800 for a landscape. *Landscape painter.* He was draughtsman to Captain Flinders's voyage of Australian discovery, was wrecked, and had many adventures. Died 1850.

Wheatley, Francis. Premiums in 1762 and 1763 for Drawings; and in 1767 for a Landscape. *Landscape and subject painter.* R.A. Pupil of Shipley. Died 1801.

Wickstead, Philip. Premiums in 1763, 1764 and 1765 for Drawings. *Portrait painter.* Pupil of Zoffany. Went to Jamaica. Died before 1790.

Wilkins, Robert. Premiums in 1765 and 1766 for Sea-pieces. *Marine painter.* Exhibited at Royal Academy 1772–1779. Died about 1790.

Williams, Penry. Silver Medal in 1820 for a Landscape in Water-colour; Silver Medal in 1821 for a Chalk Drawing. *Landscape painter.* Exhibited at Royal Academy 1827–1869. Died 1885.

Williams, William. Premium in 1758 for a Drawing. *Subject and portrait painter.* Exhibited at Royal Academy 1770–1792.

Wilson, Andrew. Gold Medal in 1810 for Stereotype Printing. Some examples of his work are given in Vol. XXVIII. of the *Transactions*, p. 317.

Winkles, H. Silver Medal in 1820 for Pen-and-Ink Drawing of St. Mary's Abbey, York. *Architect.* Joint author (with B. Winkles) of works on the English and French Cathedrals.

Woollett, William. Premium in 1759 for a Drawing. *Engraver.* His "were the first English engravings that gained notice on the Continent." "His works gave a high character to the English school" (Redgrave). Died 1785.

Woolner, Thomas. Silver Medal in 1845 for "original modelled design, entitled 'Affection.'" *Sculptor.* R.A. Died 1892.

Wright, Richard. Premiums in 1766 and 1768 for Sea-pieces. *Marine painter.* His best-known work is his "British Fishery," engraved by Woollett. Died about 1775.

Wyatt, Henry. Silver Medal in 1812, and Silver Palette in 1813 for Drawings. *Portrait and subject painter.* Exhibited at Royal Academy after 1825. Died 1840.

Wyon, Anne. Silver Medal in 1821 for Modelling Wax Flowers. She was the wife of Thomas Wyon the elder, and the mother of Benjamin.

Wyon, Benjamin. Gold Medals in 1819 and 1821 for Medal Dies. *Seal engraver.* Chief engraver of seals. Son of Thomas Wyon the elder. Died 1858.

Wyon, James. Silver Medal in 1820 for a "Head in Miniature." *Die engraver.* Engraver at the Mint. Son of George Wyon, brother of Thomas Wyon the elder.

Wyon, Thomas, Junr. Gold Medals in 1810 and 1811 for Die Engraving. The award in 1810 was for a head of Isis, adopted for the Society's Isis Medal. *Medallist.* Son of Thomas Wyon the elder. Chief engraver to the Royal Mint. Died 1817.

Hosted by Google

Wyon, William. Gold Medals in 1813, 1814 and 1820 for Medal Dies. *Medallist.* R.A. Chief engraver to the Mint. Nephew of Thomas Wyon the elder. The Medal in 1813 was for engraving the head of Ceres for the Society's Medal; that of 1820 was for designing and executing the dies for the "new large Medal of the Society," which he presented (see *Transactions*, Vol. XXXVIII. p. xxxiii.). Died 1851.

THE EXHIBITION OF BRITISH SILKS.

The Exhibition of British silken materials now being held at Prince's Skating Rink, Knightsbridge, which was opened by Her Royal Highness Princess Christian on June 5th, and visited by Her Majesty the Queen on the following day, is a most interesting and instructive one. It is the third exhibition held under the auspices of the Silk Association of Great Britain and Ireland, the first being in 1890, and the second four years later.

If judged only from the press notices of the Exhibition it might be supposed that the silk industry in this country had become extinct, but had recently been revived owing to the patriotic efforts of a few prominent advertising retail firms who deal in silks, and the work of subordinate branches of the Arts and Crafts and the Home Industries Associations. This is far from being the case, for the greatest portion of the exhibits have been made by firms which have been in the silk manufacturing trade for a century or more, and have been developing their businesses and improving the quality of their productions continuously in spite of the keen competition of foreign manufacturers, and the discouragements which often result from modern methods of trading and changes in political and social arrangements.

There can be little doubt that the chief reason why the firms which manufacture such goods as are shown at this Exhibition have been able to hold their own, and even improve their position, during the undeniably hard times which the trade has experienced, is because they have spared no efforts to improve the technical excellence, and the beauty and purity of their productions. It is quite probable that if the British silk manufacturers at the time of crisis, in the middle of the last century, had all adopted this policy in competing with their foreign rivals, there would have been, at any rate, less disaster attending the fiscal changes which enabled foreign manufacturers to flood the British market, as they did, with goods of better appearance but less intrinsic value than those of native manufacture.

This Exhibition therefore demonstrates, not the *revival* of the British silk industry, but its *survival*, improvement, and vitality.

The Exhibition, if studied in detail, provides an excellent object lesson of the evolution of the silken web from its source—the silk-producing moth—to its completion and final use by the dressmaker and furnisher. No better account, therefore, of this interesting show could be given than that afforded by noticing the exhibits which clearly show the salient points of this development.

At Stand No. 40 A, is an exhibit by Messrs. J. T. Brocklehurst & Sons, Ltd., of Macclesfield. This firm was founded in 1745, and now employs more than fifteen hundred workpeople in spinning, throwing, dyeing, winding and weaving silk. Their exhibit is a beautifully arranged collection of silk-moths, worms and cocoons, which have been bred and prepared by Mr. John Ball and his father, employees of the firm. Mr. Ball worthily keeps up the tradition of the operative silk weavers, many of whom were noted for their love of scientific recreations. The collection consists of specimens of a great many varieties of silk-producing moths, some being very large and gorgeous in colour. The most valuable, however, although the most inconspicuous in appearance, is the Bombyx Mori, the mulberry-feeding caterpillar of which genus is the Chinese silkworm. From this modest little domestic silkworm, the great bulk of silk, of incalculable value, used not only in China but wherever it has been used at all for thousands of years, has been obtained.

At Stand No. 1 A, Messrs. Durant, Bevan & Co., of London, show cocoons and reeled and thrown silk from China, Japan, Italy and India. A beautiful bundle of silk from the latter country should specially be noticed. India, if its silk industry were judiciously fostered, might become the successful rival of China as a silk producer. Messrs. G. H. Heath & Co., Macclesfield, Stand 42 B, also display skeins of thrown silk.

At Stand No. 7, Messrs. T. Clayton & Co., silk spinners of Halifax, show undyed samples of yarns of various sizes and twists, and at Stand No. 4, Messrs. Pearsall & Co., of London, exhibit silk yarns of all kinds, dyed in a great variety of beautiful colours, for which they have so great a reputation.

Undyed and undischarged, or grey, piece goods are also shown by Messrs. Clayton & Co. (Stand No. 7), and at Stand No. 2 (Mr. Webb), and Stand No. 6 (Mr. Chas. Hammond), may be seen dyed and cleaned, and re-dyed silk fabrics of all kinds.

Silk as used for embroidery is to be seen on several stands. Perhaps the most notable specimen is the cope worked by Miss Beatrice Cameron, of London (Stand 42 A), on the foundation of a gorgeous multi-coloured woven brocade.

The chief interest of the Exhibition centres, of course, in the hitherto unequalled display of woven silk fabrics. Of these, naturally those intended for furnishing purposes are the most numerous and attractive. The actual manufacturers exhibiting finished silk webs number eighteen, and the dealers, decorators, furnishers, drapers, dressmakers, etc., who have tastefully arranged exhibits showing silk fabrics in use, number thirty-three.

Messrs. Warner & Sons, of Newgate Street,

Hosted by Google

London, and Braintree, Essex (Stands No. 38, 39, 40 and 70), undoubtedly show a collection of handwoven furniture and dress silks such as could not anywhere be surpassed, if indeed they could be equalled, for perfection of technique, beauty of colour and excellence and variety of design. This firm have also erected (Stand No. 25) one of their large Jacquard mounted hand-looms, on which a sturdy typical British weaver is making a wide damask web of green silk, shot with silver thread. This loom shows the highest perfection to which the loom for weaving rich silk fabrics has attained, and is a direct descendant of the ancient Chinese draw-loom. The system of interlacing threads on it, by means of which the web is constructed, is exactly similar to that invented and practised in ancient China, as well as in the East generally and in Europe since its introduction in mediæval times.

Messrs. Morris & Co., of London (Stand No. 13), have also a fine show of silk damasks and brocades woven at their Merton Abbey works, from designs by the distinguished founder of the firm who always aimed at and almost attained perfection in all that he undertook.

A small but scarcely less noteworthy collection of handwoven furniture silks is shown by the Gainsborough Silk Weaving Co., of Sudbury, Suffolk (Stand No. 60). The collection consists of figured velvets, damasks, brocades, brocatells, etc. These for the most part are close reproductions of ancient examples in design and texture.

Prominent amongst the numerous exhibitors of silk dress-goods are Messrs. Richard Atkinson & Co. (Stand No. 23). They are weavers of original Irish poplins, both plain and figured. These are made on hand-looms by a very large number of weavers at their factories in Dublin. Messrs. Pim Brothers & Co. (Stand No. 61), in addition to an excellent exhibit of poplin webs, show a model hand-loom, fitted up for weaving plain poplins, and also materials used in the manufacture of their goods in Ireland.

Messrs. Bailey, Fox & Co., of London, Plaistow in Essex, and Sudbury, Suffolk (Stand No. 29), have a good display of hand and power-loom woven silks and velvets. Some of their goods are still made on the hand-looms of Bethnal Green.

Other firms show silk dress-goods in great variety, made entirely on power-looms, but the space at disposal for this notice forbids reference to them in detail, as it does also of the many excellent and tasteful exhibits of the firms who buy and retail, or use silken fabrics for furnishing or dressmaking.

In conclusion, it may well be pointed out that the best way to encourage the silk weaving, as well as most other British industries, is to inquire for, and insist on having, goods which are not only beautiful in appearance but are well made, of honest unadulterated materials. Such a demand, if general, would undoubtedly be more effectual than the merely sentimental demand for British goods simply because they are British.

LUTHER HOOPER.

CORRESPONDENCE.

THE MANUFACTURE OF NITRATES FROM THE ATMOSPHERE.

The following figures and remarks on the general nitrogen situation, in amplification of some statistics given by Mr. Kilburn Scott, may be of interest:—

ADDITION TO TABLE I. ON PAGE 646 OF THE *Journal* (completing the record from 1906 to 1912).

Production of Sulphate of Ammonia in the United Kingdom.	1911.	1908.	1907.
Gasworks	169,500	165,000	165,000
Ironworks	20,000	18,000	21,000
Shaleworks	60,000	53,500	51,000
Coke ovens and producer-gas plants	129,000	85,000	75,500
Total . .	378,500	321,500	312,500

It should be noted that the above figures only apply to the production in the United Kingdom, and that in 1906 some 69 per cent. of the output of these islands was exported, while the ratio of export has gradually increased to 78 per cent. in 1911; so that the home consumption, which was in 1906 about 89,700 tons, was only some 83,250 tons in 1911—that is, had actually decreased in the period by over 7 per cent.

The figures of the home output and consumption, however, furnish no idea of the world's production, which for certain years I am able to estimate as follows. It should be noticed that, as each year's output is pretty well consumed, the stocks held in the various countries do not count:—

WORLD'S OUTPUT OF SULPHATE OF AMMONIA.

1860	10,000 tons
1902	545,000 ,,
1907	845,000 ,,
1909	1,000,000 ,,
1911	1,210,000 ,,

The table given on page 757, which shows the consumption of nitrate of soda in the principal countries of the world for comparison with Table II. of Mr. Scott's lecture, will be of interest. The data are derived from the "Engrais."

Comparing the consumption of Chili nitrate in the United Kingdom with the consumption of sulphate of ammonia, we find that whereas in the latter the consumption has fallen off some 7 per cent., the former has from 1906 to 1911 increased some 20 per cent.

Even a cursory glance at the tables of the world's production, and the consumption in various countries of nitrogenous fertilisers, shows that the production of sulphate of ammonia in the United Kingdom is increasing at a much lower ratio than it is elsewhere, and that the consumption is either stationary or decreasing; while the consumption of nitrate of soda, though increasing on an average 4 per cent. per annum, is not nearly so active as

Italy	46,620	41,940	45,000	52,390	43,370	51,780
Austria-Hungary	6,880	6,120	7,620	12,180	5,590	5,100
Spain	4,670	5,820	6,950	15,990	10,490	8,670
Sweden	5,320	5,370	2,000	—	2,400	2,290
Denmark	—	2,360	—	—	—	3,320
Egypt	—	—	—	—	—	25,680
United States	355,000	355,000	310,000	410,000	502,000	551,000
Other Extra European States	38,000	43,000	46,000	56,000	83,000	77,000
Unsold Stocks held at end of year	2,580	23,300	137,530	190,880	68,280	180,150
Total Exports from Chili	1,640,000	1,672,000	1,970,000	2,108,600	2,308,200	2,420,400

either in Germany, France, or the United States, where the average rate of increase per cent. per annum has amounted to 5·6, 9·3 and 11·6, respectively, in the period between 1906 and 1912. Probably to a considerable extent the comparatively slower rate of increase in the agricultural demand for nitrogenous fertilisers in this country, is due to having started the use of artificials at a relatively higher stage of manuring than the three other countries. Owing to the countryside here being more plentifully provided with stock than was the case there, it does not require nearly as much artificial manure. Some of the discrepancy may also, no doubt, be accounted for by the fact that relatively more of the nitrogenous material is used up in manufactures there than in the United Kingdom.

There can be no doubt, however, that it would be better for British agriculture if increasingly larger amounts of artificials were used, or in other words if more intensive cultivation were practised, as more advantage would be taken of our natural advantages of soil and climate, than our farmers at present see their way to.

Here is an opportunity for the new manures, "nitrolim" (calcium cyanamide) and nitrate of lime, to establish themselves, which they could not hope for were the field more efficiently occupied by older competitors. The farmer must progress at a much higher rate of acceleration in the use of nitrogenous fertilisers, if he is to hold his own against the competition of the foreign-grown produce with which we are increasingly flooded year by year. Also the chemical manufacturer, who is in an analogous position, must gird his loins and become a far greater consumer of the raw material with a nitrogen basis than he has been in the past, if he means to hold his own in the world of chemical products. Patriotism should have something to say in the matter also, as Sir William Ramsay and your lecturer both very pertinently pointed out.

Henry E. P. Cottrell.

I beg to thank you for forwarding me the *Journal* of the Society of May 17th. I think the following points may perhaps be of interest to your readers.

With reference to the comparison of the Schönherr furnace with the Eyde-Birkeland furnace, the impression is conveyed by the paper that the Schönherr furnace is more expensive than the other. This is, in my opinion, not the case; and, moreover, in any comparison of the two processes, the important fact must be borne in mind that the Schönherr furnace delivers the gases richer in nitrogen oxides, than does the Eyde-Birkeland furnace. Consequently, for the same output of lime-saltpetre, a smaller absorption plant is necessary when using Schönherr furnaces than when using the Eyde-Birkeland furnace.

The pictures given on page 653 of the *Journal* are, in a way, misleading; some mistake has occurred. The first print, given quite correctly, shows one of the eight rows of twelve Schönherr

Hosted by Google

furnaces as they are set up at Rjukan; the lower one, Fig. 7, is entitled "Rjukan Saltpetre Factory, View of Furnace Room showing twelve Eyde-Birkeland Furnaces." This is a mistake; the print is from a photograph of the Notodden factory, and the twelve furnaces shown are the small type of the Eyde-Birkeland furnace, not the large type utilising 3,000 kilowatts, of which there are not twelve set up at Rjukan. Eighty per cent. of the energy developed at the Rjukan factory is employed in Schönherr furnaces, and 20 per cent. in the Eyde-Birkeland furnaces.

I should like to be permitted to deal with two points raised by the Chairman, Sir William Ramsay, at the discussion. He refers there to a patent of Professor Guye, taken out "about 1898," and expresses the view that the Schönherr furnace is simply a modification of Professor Guye's invention, and that he had difficulty in understanding how patents came to be granted to Schönherr, unless, indeed, they were merely for improvements or modifications of Professor Guye's invention.

I am quite at a loss to understand these comments. No patent at all of Professor Guye that bears any resemblance whatever to the Schönherr patents is known to me, and the date "about 1898," mentioned by Sir William Ramsay, gives no assistance in finding any such patent. Again, in none of the countries in the world where patent applications are subjected to examination before they are granted, has any patent of Professor Guye's been cited against the Schönherr patents for the long stable electric arc. These latter contain the statement that this long stable electric arc is an entirely new phenomenon hitherto unknown either in nature or in the arts; this statement has already stood the test of litigation, in some cases its truth has been admitted; in one, where it was contested, the decision was in favour of the Schönherr patent on that point and every other.

Further, Professor Guye delivered an exhaustive lecture on "La Fixation Industrielle de l'Azote," before the Société chimique de France, on May 24th, 1909. He dealt with his own work, and with the furnaces of Schönherr and others, and made no such claim as that put forward by Sir William.

Sir William Ramsay is also represented as saying that the nitrate of calcium originally manufactured could not be handled, as it turned wet when exposed to the air. Dr. Messel suggested making a basic calcium nitrate, and made a free gift of this suggestion to the Norwegian company; without such aid the product would have been totally unworkable, as it absorbed moisture as quickly as chloride of calcium does.

I recollect that about four years ago Dr. Messel, in the discussion of a paper by Mr. Eyde, did suggest the manufacture of basic nitrate of lime instead of neutral nitrate. I do not know if this is the suggestion to which Sir William Ramsay referred, but in any case there is great confusion as to the facts. The product manufactured to-day is not the basic nitrate of lime, but the neutral nitrate, just as it was long before the suggestion of Dr. Messel that I refer to. The commercial product was originally neutral nitrate of lime, and is so to this day. Experiments have of course been made with basic nitrate, but they have been, so far, unsuccessful.

Thanking you again for your courtesy in giving me the opportunity of taking part in this discussion.

ERNEST F. EHRHARDT.

Ludwigshafen a/Rh.

Je vous remercie de l'aimable communication de l'article de M. Ern. Kilburn Scott, contenue dans votre numéro du 17 mai, 1912; j'en ai pris connaissance avec grand intérêt.

Il est difficile pour une personne qui n'a pas pris part à une discussion d'y intervenir après coup; néanmoins, je me permettrai de vous donner les quelques indications suivantes:

Nos premiers brevets, sur lesquels Sir William Ramsay a attiré l'attention, datent du 15 juillet 1895 (D.R.P.), et non pas de 1898 ainsi que cela a été imprimé par erreur; ces brevets résultent de travaux que j'ai effectués avec la collaboration du Professeur C. E. Guye et de M. Aloys Naville et dont on trouvera l'historique dans un rapport récent de la Société d'Encouragement ("Bulletin de la Société d'Encouragement pour l'Industrie Nationale," Paris, février 1911). C'est dans nos brevets de 1895–96 que sont formulés les principes suivants appliqués depuis par la plupart des constructeurs:

"Pour obtenir le meilleur rendement possible en oxyde d'azote par rapport à l'énergie électrique consommée, il est indispensable, toutes choses égales d'ailleurs: 1°) de soustraire rapidement les gaz à l'action des décharges électriques avant d'atteindre la teneur limite en oxydes d'azote; 2°) de renouveler constamment et rapidement les gaz soumis à l'action de ces décharges; 3°) de donner à la chambre d'oxydation une forme aussi rétrécie que possible par rapport à l'espace où se produit les décharges électriques, de façon à soumettre la masse totale du gaz à l'action des hautes températures produites par ces décharges."

Dès l'année 1903 nous obtenions à Genève, à la suite d'une véritable marche industrielle de 6,000 heures de jour et de nuit, une demi-tonne environ d'acide nitrique aqueux à 40% NO_3H; les appareils présentant une sécurité de marche assez grande pour ne demander aucune surveillance pendant leur fonctionnement de nuit.

Des échantillons de l'acide brut ainsi obtenu et des échantillons d'acide redistillé furent envoyés à quelques fabriques; voici à titre de curiosité le résultat de l'analyse qui en fut faite à Ludwigshafen, en 1903, dans les laboratoires de la Badische Anilin & Soda Fabrik, sur les ordres de M. le Dr. G. Brunck, à l'obligeance duquel je dois les chiffres suivants:

Le produit brut, recueilli dans les appareils en grès, contenait 39·6% HNO_3, 0·2% HNO_2 et un peu

Hosted by Google

d'acide chlorhydrique et d'acide sulfurique, ces deux derniers provenant du matériel en grès et des joints au sulfate de baryte et au silicate de sodium. Le produit distillé contenait 46·7% HNO_3, 0·02 HNO_2, des traces de HCl et pas de H_2SO_4.

Pour tous les détails techniques relatifs à nos procédés qui ont été mis en œuvre à Genève au moyen de fours de 200 et 400 kw., je me borne à citer ici les conférences détaillées que j'ai données sur ce sujet, en 1906, devant la "Society of Chemical Industry" à Londres, en 1909, devant la "Société chimique de France," à Paris, et en 1910 devant la "Société d'Encouragement pour l'Industrie Nationale," à Paris. La seule particularité nouvelle sur laquelle il me paraisse utile d'attirer ici l'attention, concerne un procédé, étudié avec la collaboration de MM. les Drs. Darier et van Vloten, qui permet de transformer directement le chlorure de sodium en nitrate de sodium, sans perte d'acide nitrique.

En ce qui concerne l'avenir économique des procédés industriels pour la fixation de l'azote, il est certain que ceux-ci sont appelés à se développer en Europe, ainsi qu'on peut d'ailleurs le constater par les statistiques intéressantes publiées par M. Scott. Je crois néanmoins que les usines électrochimiques susceptibles de produire les quantités colossales d'engrais azotés qui seront indispensables dans l'avenir pour l'agriculture (la consommation mondiale du nitrate du Chili et de sulfate d'ammoniaque dépasse déjà trois millions de tonnes par an, et augmente chaque année d'environ de 10% sur la consommation de l'année précédente) s'établiront nécessairement dans les régions des grands fleuves: Amérique du Sud, Indes, Afrique. En particulier, il convient de porter son attention sur les grands fleuves du plateau africain, qui parviennent presque tous à la mer par des rapides présentant souvent, sur des distances relativement courtes, des différences d'altitude de 3 à 4 cents mètres. Ces conditions, jointes au débit d'eau énorme de ces cours d'eau, sont éminemment favorables à l'établissement d'installations hydro-électriques très avantageuses, en ce sens que par la captation d'une seule chute, il est aisé d'obtenir une puissance d'un demi-million de HP, tandis qu'en Europe la captation d'une seule chute donne rarement plus de 20,000 HP.

Les pays qui possèdent, comme la Grande Bretagne, de pareilles richesses naturelles, ont ainsi une occasion exceptionnelle de les mettre en valeur; les opérations de ce genre paraissent d'autant moins hasardeuses que les quantités d'azote fertilisant réclamées chaque année par l'agriculture sont si considérables que pour suffire seulement à l'augmentation actuelle de la consommation mondiale en nitrate de soude, soit environ 200,000 tonnes par an, il faudrait équiper chaque année des forces motrices représentant une puissance totale de 400,000 HP. environ. C'est une entreprise que peuvent seuls faire les pays qui disposent de capitaux considérables, car en comptant 500 francs par HP.-équipé, le capital nécessaire pour installer les usines hydro-électriques et les installations électrochimiques nécessaires pour la fixation de l'azote, on voit qu'il faudrait immobiliser chaque année une somme de francs 200,000,000 — soit £8,000,000.

Veuillez agréer, cher Monsieur, l'assurance de ma considération très distinguée.

Genève. PH. A. GUYE.

I do not know the date of Schönherr's patents, not having studied them, but I do know that in 1905 or 1906 I saw at Geneva high tubes, fitted with a perfectly stable arc, bearing, so far as I remember, a very close resemblance to the diagram of Schönherr's apparatus given by Mr. Kilburn Scott.

Professor Guye has dealt with the subject of the original patents, so that I need not allude to them. WILLIAM RAMSAY.

GENERAL NOTES.

THE OPTICAL CONVENTION.—In connection with the sitting of the Optical Convention, which opens on the 19th inst., an exhibition of optical and allied instruments will be held in the eastern portion of the Southern Galleries of the Science Galleries of the Science Museum at South Kensington. The Exhibition will be distributed into three departments: (1) The Trade Exhibition.—In this collection British optical manufactures will be found to be very fully represented. The exhibiting section of the trade will include nearly all the leading manufacturers of optical instruments and apparatus in the United Kingdom; (2) the Loan Collection.—The loan collection will comprise some extremely interesting instruments from the historical point of view, and also a considerable number of instruments of special scientific interest. In addition to these, a temporary library will be formed by a collection of volumes bearing upon optics, lent by the leading publishers and scientific societies. In connection with the library, it may be mentioned that members will find the admirably-appointed science library accessible in an adjacent part of the Science Museum, and the equally well-equipped art library of the Victoria and Albert Museum on the other side of Exhibition Road. In connection with the loan collection, it is appropriate to say that the Science Museum collection of optical instruments will be easily accessible to members attending the Convention, since it is contained in the adjacent West Galleries of the Science Museum; (3) Demonstrations.—The large room beyond the reception room in the members' annexe, will be devoted to diagrams and apparatus to be used in illustration of the papers to be read. In addition to this, there will be a public demonstration room on the first floor, in which from time to time the exhibitors of instruments and apparatus of special interest will give public demonstrations. These demonstrations will often be arranged at short notice, and by private communication, so that visitors to the Exhibition interested in the particular examination of any special instrument may make arrangements

Hosted by Google

with the exhibitors for such demonstrations at mutually convenient times. A third form of demonstration, which will be arranged in connection with the Exhibition, consists in the reproduction of certain historical experiments, which have contributed notably to the development of the science of optics. A room, to be called the "Isaac Newton" room, will be fitted up with apparatus constructed in accordance with the description given by Newton in his "Opticks," of the apparatus which he himself used in some of the principal experiments described in that work. This apparatus will be so fitted up that the experiments described by Newton may be repeated with this *facsimile* apparatus; and, with a powerful arc lamp to replace the sun, it will be possible to repeat Newton's demonstrations at all times of the day, and under all conditions of weather. The preparation and care of this exhibit have been taken in hand by Professor Silvanus P. Thompson. Further particulars of the papers to be read, etc., will be found below, under the heading "Meetings for the Ensuing Week."

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY.—The fourth annual report of the governing body of the Imperial College of Science and Technology shows that the total number of students during the year 1910–12 was 887, as compared with 788 for the previous session. The number of students attending post-graduates has been steadily increasing from 30 in 1907–08 to 136 last year. A statement recently prepared shows that 24 per cent. of the students were born in London, 45 per cent. in England (other than London), 7 per cent. in Scotland, Ireland and Wales, 13 per cent. in the British Colonies and Dependencies, and 11 per cent. in foreign countries. The report also contains some account of the research work which is being conducted in the various departments of the College.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 17...Victoria Institute, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Sir Andrew Wingate, "Modern Unrest and the Bible."

Chemical Industry (London Section), at the Chemical Society's Rooms, Burlington House, Piccadilly, 8 p.m. 1. Mr. W. H. Perkin, "The Production and Polymerisation of Isoprene and its Homologues." 2. Mr. W. J. Dibdin, "A Hand Photometer." 3. Messrs. J. Newton Friend and W. J. Davison, "The Oxidation of the Drying Oils."

TUESDAY, JUNE 18...Statistical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Mr. A. L. Bowley, "The Measurement of Employment—an Experiment."

Society of Painters in Tempera, Crosby Hall, Cheyne-walk, Chelsea, S.W., 8.15 p.m. Professor Selwyn Image, "The Future of Mural Decoration."

WEDNESDAY, JUNE 19...Optical Convention, Imperial College of Science, South Kensington, S.W., 8 p.m. 1. Presidential Address. 2. Conversazione.

Geological, Burlington House, W., 8 p.m.

Microscopical, 20, Hanover-square, 8 p.m. 1. Lord Avebury, "Notes on Pollen." 2. Dr. J. F. Gaskell, "Demonstration of a Method of obtaining Frozen Sections after embedding in Gelatin." 3. Messrs. Heron-Allen and Mr. A. Earland, "On some new Astrorhizidae and their Structure."

Meteorological Society, 70, Victoria-street, S.W., 4.30 p.m. 1. Mr. W. W. Bryant, "The Adoption of a Climatological Day." 2. Mr. A. P. Jenkin, "A Three-Year Period in Rainfall."

THURSDAY, JUNE 20—Optical Convention, Imperial College of Science, South Kensington, S.W., 10 a.m. 1. Mr. J. Rheinberg, "The Micro-Spectra Method of Natural Colour Photography." 2. Mr. C. F. Lan Davis, "Sector Shutters." 3. Mr. R. W. Cheshire "The Transmission of Visible Light through Photographic Lenses." 4. Mr. P. Everitt, "On the Principal Surfaces of a Lens." 5. Paper by Mr. T. Smith.

8 p.m. Public Lecture by Professor Stirling, "Some Optical Illusions."

Antiquaries, Burlington House, W., 8.30 p.m.

Linnean, Burlington House, W., 8 p.m. 1. Señor Ignacio Bolivar, "Les Euorthoptères des Seychelles." 2. Mr. C. G. Lamb, "Diptera: Loncheidæ, etc., of the Seychelles." 3. Mr. Hugh Scott, "The Coleoptera of the Seychelles." 4. The late Dr. G. Budde-Lund, "Terrestrial Isopoda, particularly considered in relation to the Distribution of the Southern Indo-Pacific Species." (These four papers form part of the reports of the Percy Sladen Expedition.) 5. Mr. H. Stuart Thompson, "Selection of coloured drawings of Alpine Flowers by Mr. George Flemwell." 6. Miss Nellie Bancroft, "On some Indian Jurassic Gymnosperms." 7. Mr. Carl Christensen, "The Ferns of the Seychelles and Aldabra."

Chemical, Burlington House, W., 8.30 p.m. 1. Sir William Ramsay, "The Formation of Neon as a Product of Radioactive Change." 2. Mr. S. U. Pickering, "The Colour Intensity of Copper Salts." 3. Messrs. P. C. Ray, N. Dhar, and T. De, "Nitrites of the Mercurialkyl- and Mercurialkylaryl-ammonium Series." (Part II.) 4. Mr. I. Masson and Sir William Ramsay, "An Analysis of the Waters of the Thermal Springs of Bath." 5. Messrs. H. J. H. Fenton and W. A. R. Wilks, "Studies on certain Aliphatic Hydroxy-acids." 6. Mr. J. Kenner, "Formation of Seven- and Eight-membered Rings from 2 : 2¹-ditolyl." 7. Messrs. W. H. Glover and T. M. Lowry, "Studies of Dynamic Isomerism. Part XIII.—Camphocarboxamide and Camphocarboxypiperidide. An illustration of Barlow and Pope's Hypothesis." 8. Messrs. T. M. Lowry and W. H. Glover, "Studies of Dynamic Isomerism. Part XIV.—Successive Isomeric Changes in Camphocarboxamide and Camphocarboxypiperidide." 9. Messrs. G. G. Henderson and W. Caw, "Contributions to the Chemistry of the Terpenes. Part XIII.—The Preparation of Pure Bornylene."

Historical, 7, South-square, Gray's Inn, W.C., 5 p.m. Mr. B. K. Henderson, "The History of the Commonwealth Charters to the Towns."

FRIDAY, JUNE 21...Optical Convention, Imperial College of Science, South Kensington, S.W., 10 a.m. Joint Meeting with the Physical Society. 1. Dr. G. F. C. Searle, "Demonstration of Apparatus for the Teaching of Optics." 2. Mr. J. W. Gordon, "Diffraction Patterns." 3. Mr. E. H. Rayner, "The Shape of Scales required for Reflecting Instruments with Concave Mirrors." 4. Messrs. C. C. Patterson and B. P. Dudding, "The Visibility of Distant Lights." 5. Dr. T. M. Lowry, "Some Points in the Use and Design of Refractometers." 6. Messrs. J. S. Dow and V. H. Mackinney, "Recent Advances in the Measurement of Light and Illumination."

8 p.m. 1. Professor S. P. Thompson, "The Trend of Geometrical Optics." 2. Messrs. A. C. Jolley and A. J. Bull, "The Measurement of Colour." 3. Dr. J. A. Harker, "Optical Pyrometry."

NOTICES.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Fifty-Eighth Annual General Meeting, for the purpose of receiving the Council's report and the Treasurers' Statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new members, will be held, in accordance with the By-laws, on Wednesday, June 26th, at 4 p.m.

(By order of the Council),

HENRY TRUEMAN WOOD, *Secretary.*

NORTH LONDON EXHIBITION TRUST.

In 1865 the Committee of the North London Working-classes and Industrial Exhibition (1864) presented to the Society of Arts a sum of £157, the balance of the surplus from that Exhibition, with a view to the annual award of prizes for the best specimens of skilled workmanship exhibited at the Art Workmanship Competitions of the Society of Arts. The Art Workmanship Competitions were discontinued after 1870, but since that date various prizes have been awarded under this Trust. Prizes were offered to the students of the Artistic Crafts Department of the Northampton Institute, Clerkenwell, in 1903, and have been continued annually to the present time. These have been awarded, for the present year, as follows:—

Senior Section—First Prize of £3 and a Certificate to Ernest Creedy for a Bound Book.

Junior Section—Prize of £1 10*s*. and a Certificate to Oscar John Mekelburg for a Pendant.

Prize of £1 10*s*. and a Certificate to Thomas Chilcott for a Bound Book.

A Certificate only to William Alfred Tresadern for a Bound Book.

The awards have been made on the recommendation of Mr. Alan S. Cole, C.B.

EXAMINATIONS.

The results of the Advanced Examinations (Stage III.) were published on the 15th inst. The results of the Intermediate Examinations (Stage II.) will be published about the middle of July, and those of the Elementary (Stage I.) in August.

THE ROYAL SOCIETY OF ARTS.*

By Sir Henry Trueman Wood, M.A.,
Secretary of the Society.

VIII.—The Society and the Fine Arts. (1755–1851.)

(Concluded.)

Besides the prizes given to artists as encouragement for technical skill or in appreciation of genius, there were also a certain number for inventions and improvements connected with the Arts. A good many of these are trivial, but there are others of interest and some of importance in the history of the technics of Art.

A few prizes were at various times offered and awarded for artists' instruments and materials. In 1764 a premium of thirty guineas was given to Thomas Keyse for a method of fixing crayon drawings. Keyse was a still-life painter of some repute. He was also the keeper of Bermondsey Spa, where he had a gallery of his own works. The masterpiece was the interior of a butcher's shop, and over it certain of the wits of the time made merry.

In 1772 twenty guineas were given to Joseph Pache for preparing crayons, and "establishing a manufactory thereof in England." In 1781 the greater silver Palette was awarded to Thomas and William Reeves for improved water-colours. In 1794 the Palette and twenty guineas were awarded to George Blackman for his method of making oil-colour cakes. These were reported on favourably by Cosway and by Stothard, and the method of their preparation is described in the *Transactions*.† In 1803 a silver medal and ten guineas were given to James Harris for a syringe for preserving oil-colours. The syringe was of the ordinary sort, when it was filled with colour the piston was inserted and secured by screwing on the head. It was certainly an improvement on the then existing method of supplying artists' oil-colours in bladders, and received the approval of Sir Thomas Lawrence, P.R.A.

An award to William Brockedon in 1823 for a rest for painters engaged in minute work, may be noticed on account of the inventor's personality, rather than because of its intrinsic importance. Brockedon was a versatile genius, an excellent painter, a man of science (he was an F.R.S.), and an ingenious inventor. He was Chairman of the Committee of Polite Arts 1824–1831.

Besides these there were rewards for various drawing instruments and appliances, sculptors' instruments, etching fluids, drawing tablets, pencils, paper for copper-plate printing, etc.

Reference to some of these has been made in a previous article (*Journal*, January 26th), which also records the award to Senefelder for the invention of lithography.

One of the most popular things the Society ever did was its offer of a medal for a shilling colour-box, and mention may be made of it here, though we are anticipating by some half a century at least the proper course of the Society's history. This offer was made in 1851, and in the following year the medal was awarded to J. Rogers, of 133, Bunhill Row, E.C. The box has long since been obsolete, or rather has been superseded by better appliances of the same sort; but it was a very great advance on anything which existed at the time, and its enormous popularity was sufficient evidence of its value.

The proposal was put forward by Henry Cole, and was carried out with the promptitude that characterised all that remarkable man's ideas. The offer was advertised in September, 1851. The competing boxes were received on December 1st, and the award was published on January 14th, 1852. The medal was presented at the distribution of awards held by Prince Albert in 1853. According to a statement made by Sir Henry Cole,* the maker reported to him in 1870 that eleven millions of these boxes had then been sold.

At the same time a medal was offered for a cheap set of drawing instruments, to contain a pair of compasses, a drawing square, and a graduated ruler. This was awarded to J. and H. Cronmire, of Cottage Lane, Commercial Road, for two sets of instruments, one to be sold at 2*s.* 6*d.*, and one of a superior character at 6*s.* A good many of these were sold, but the drawing instruments never attained the popularity of the shilling colour-box.

* The previous articles of the series appeared in the *Journals* of June 9th and 16th, September 22nd and 29th, and November 3rd, 1911, January 12th, 19th and 26th, April 5th, and June 14th, 1912.

Two prizes awarded in 1822 and 1823 mark an important though temporary modification in the technique of the engraver, the substitution of steel for copper plates. Although steel had been employed for etched plates by Albert Dürer in 1510, it had never really come into use, and until the middle of the nineteenth century copper was in practice always used by engravers. It had the advantage of being easily worked upon, and the disadvantage of only giving a small number of impressions. The precise date of the invention of the modern steel-plate seems uncertain, and the name of the inventor (if any single person can claim the credit) is also doubtful. S. T. Davenport * attributes the invention to Jacob Perkins, whose "siderographic" process for printing banknotes was mentioned in a previous article.† In the volume of the *Transactions* for 1820, in which the process is fully described, Perkins states that his method had been "in successful operation many years in America," and it certainly involved the use of engraved steel plates, but he makes no claim to having been the first to engrave on steel. He merely refers to such plates as if they were in ordinary use.‡ In the specification of his patent, taken out in October, 1819, Perkins describes a method of "decarbonating" and "reconverting" steel plates for engraving, and refers to the use of steel plates as a thing commonly known.

Early in the century Abraham Raimbach, the engraver, made some unsuccessful experiments with steel, but it seems to have been considered that the difficulties of engraving on the metal, even in a soft state, and of afterwards hardening it, were practically insuperable.

Raimbach, in his "Memoirs,"§ does not refer to his experiments, and he only alludes to steel-plate engraving as a cause of the deterioration of the art from the numbers of plates produced to comply with the popular demand, and the consequent inferiority of the work.

In 1822 T. G. Lupton was awarded a gold medal for introducing the use of soft steel for mezzotint. In a communication on the subject,‖ he says that the method of working is precisely the same as for copper plates, except that greater strength has to be used in laying the ground, and the plate has to be gone over with the tool a greater number of times.

The medal was evidently given to Lupton under the idea that he was the first to employ steel, at all events for mezzotint, and in his paper he appears to claim this credit for himself. As a matter of fact, however, he seems to have been anticipated by William Say, since there is in the collection of the British Museum a mezzotint by the latter engraver, which is dated 1817, and this is said to have been printed from a steel plate. It is from a portrait by G. Dawe, R.A., of the Princess Charlotte, the daughter of George IV., who died in 1817. This has always been believed to be the first mezzotint on steel, and inasmuch as Lupton's plate, submitted to the Society in 1822, appears from his paper to have been his first success, there is no reason to question Say's claim to priority.

In 1823 a gold medal was given to Charles Warren for "Improvements in the art of engraving on steel." These improvements consisted in substituting a plate of soft steel for the ordinary copper-plate. His process is described in the *Transactions*,* and it appears that he was led to experiment in the use of steel from early training in engraving for calico printers, and from observation of methods used in ornamenting articles of cast-steel. He began by decarbonising steel plates, and, after engraving on the softened steel (or iron), re-hardening it, but he found that plates of sufficient thinness for the purpose were apt to warp in the hardening, while there were other difficulties in using thicker plates. He was then led to try printing from the plates in their soft state, and found no difficulty in producing large numbers of impressions. The details of the method of softening the plates were improved, and it was found that editions of 4,000 and 5,000 prints could be produced without the plates showing signs of deterioration. Warren died suddenly, after the award of the medal, and before its presentation, so the account of his process in the *Transactions* is contained in a report by the committee, not in a communication from himself. So far as can be judged, the method is principally intended for etching, though available also for line engraving.

Probably the truth about the invention of steel-plate engraving is that many engravers tried to employ steel. Perkins was successful with the small plates that served his purpose, and probably those who tried to use larger plates found difficulties in the processes of

* "Engraving and other Reproductive Art Processes," *Journal*, Vol. XIII. p. 134.

† *Journal*, Jan. 26th, p. 270.

‡ E. Turrell, in a communication (*Transactions*, Vol. XLII. p. 43), says that Perkins first used steel plates "in his banknote manufactory in the United States."

§ "Memoirs of Abraham Raimbach," 1843.

Hosted by Google

softening and hardening the steel. Very likely, therefore, it was not till Say (possibly) and Lupton and Warren (certainly) found that steel plates could be employed without the necessity for hardening them, that such plates came into extensive use. That they did come into such use, and very rapidly, is, of course, well known. The facilities they afforded for printing large editions enabled publishers to produce the flood of "Annuals" which were popular in the thirties and forties of the last century, and served to popularise Art, if they did little to elevate it.

The copper-plate came to its own again when it was found possible to deposit upon its surface a thin film of steel, or rather iron, and thus to give it a hard "face" which would stand the wear of printing. The process was termed "acierage," and was, as all the evidence goes to show, the invention, about 1858 or a little earlier, of Henry Garnier, a Paris engraver, with whom F. Joubert, also an engraver, coöperated. Joubert brought the process over to London, and ten years later, in November, 1858, he read a very full description of it before a meeting of the Society.* The process was patented in England, March 29th, 1858, by E. A. Jacquin, as a "communication" from Henry Garnier. The process, which was merely a method of electro-deposition, came rapidly into use, and for a time was associated with Joubert's name. It proved to be of the utmost value, and has ever since been extensively applied to copper-plates of every description, including those produced by photographic methods.†

When steel was first used for etching, a difficulty was found in discovering a suitable etching fluid. Nitric acid acted too violently, and Warren recommended a solution of copper nitrate, acidified with nitric acid. In the following year (1824) Edmund Turrell‡ received a gold medal for his etching fluid, composed of pyroligneous acid, nitric acid and alcohol, and this fluid, with some modifications and the omission of the spirit, seems to have been largely used for some years for etching steel.

A few other awards in connection with plate-printing may be mentioned. In 1773, Richard Samuel received fifteen guineas for a tool for laying mezzotint grounds. Samuel was a portrait painter of no great merit, according to Redgrave. In 1776 Robert Lawrie (or Laurie), an engraver, who took several of the Society's prizes, received a "Bounty" of thirty guineas for an invention which facilitated the printing of mezzotint plates in colours.

* *Journal*, Vol. VI. p. 15.

† S. T. Davenport, in his paper above mentioned, quotes a letter from Joubert, in which it is stated that the process was patented in 1848 by M. Jacquin; but this is merely an unfortunate misprint.

‡ See his paper in Vol. XLII. of the *Transactions* above referred to.

In 1810 a silver medal and thirty guineas were given to John Hassell for improvements in the aquatint process.* His invention consisted in drawing direct on the plate with a specially prepared ink, which, when removed from the varnished plate, left the lines clear for etching. Such devices were at a later date known to and employed by aquatint workers, but the method may have been new at the date of the award.

The idea of producing prints from wood blocks in various colours is very old, and the method of colour printing for which William Savage obtained a silver medal and fifteen guineas in 1825 really involved no novel principle. He used different blocks for the different colours, and employed various devices for ensuring accurate register. Savage produced some excellent work, and devoted much attention to the subject, on which he wrote a book.†

The work done by the Society in encouraging the art of die-sinking during the latter part of the eighteenth century deserves special note. In the 1758 prize list is an announcement that "The Medallic Art being capable of great Improvement in this Nation," a prize of twenty guineas will be given for a copper medal, "after a model first produced by the candidate, and approved by the Society," the competition being limited to persons under the age of twenty-five. The offer was continued for several years, the terms being slightly varied. The age limit was raised to forty, and a second prize was offered for younger candidates.

The effort to improve the character of British medals was successful, for the result was that a number of admirable medals were produced. In some cases the candidates were allowed to choose their own subjects, in others the subjects were specified by the Society. Most of the selected subjects were British victories, of which there were, fortunately, about that time a sufficient number to provide ample choice. Several of the prizes were taken by members of the Pingo family, and, according to a statement by Dossie,‡ the designs from which the dies were cut were prepared by their father, Thomas Pingo, the engraver to the Mint.

* *Transactions*, Vol. XXVIII. p. 97.

† "Practical Thoughts on Decorative Printing," 1822.

‡ "Memoirs of Agriculture," Vol. III. p. 428.

Hosted by Google

Thomas Pingo himself did not enter for any of the competitions, but he was paid eighty guineas for cutting the dies for the Society's first medal. His two sons, John and Lewis, carried off a number of the awards for medals, and his other children, Benjamin, Henry and Mary, took numerous prizes in other classes. Thomas Pingo was an Italian who came to England, and was appointed Engraver to the Mint, an office afterwards filled in succession by his sons, John and Lewis. In October, 1758, John Pingo produced a model for a medal with a head of Britannia, and the inscription, "O fair Britannia, hail!" On the reverse was the figure of Victory standing on the prow of a ship, with the inscription, "Louisburg taken, MDCCLVIII." This referred to the taking of Louisburg and Cape Breton by the English, under Amherst and Boscawen, in July, 1758. The model was accepted, but before the year was out, the small island of Goree, on the western coast of Africa, was captured from the French by Admiral Keppel, and the glory of this achievement was supposed to eclipse that of the taking of Louisburg. Pingo was therefore directed to make a new die for the reverse of his medal, and to cause the words "Goree taken" to replace "Louisburg taken."

In connection with the conquest of Canada four other medals were produced besides the one transferred from Canada to Africa—the first by John Pingo (1759) with the inscription "Quebec taken"; a second by Lewis Pingo (1761), "Canada subdued"; a third by Lewis Pingo (1760), commemorating the capture of Louisburg in 1758, and a fourth by John Kirk (1763), "Conquest of Canada completed." In 1762 a prize was given to John Kirk for a medal in commemoration of the brilliant exploit of Admiral Hawke off Belleisle, on November 20th, 1759. Kirk had been a pupil of J. A. Dassier, who had been engraver to the Mint about 1750. He died young in 1776. In 1763 John Pingo received a prize for a medal, the subject of which was the Battle of Minden, fought in August, 1759, and in 1765 one for a medal commemorating the Battle of Plassy, June 23rd, 1759.

Lewis Pingo also received, in 1764, 1771, and 1772, three other premiums for medals commemorating victories, the capture of Guadaloupe in 1759; the naval victory at Lagos in 1759; the capture of Havana in 1762.*

Besides these, John Pingo received an award in 1762 for an allegorical group of the Arts—"Painting, Sculpture, and Architecture"; and Lewis Pingo two awards, one in 1759 for a medal representing the granting of Magna Charta, and a second for a portrait medal of King George III. John Kirk also received a premium in 1762 for engraving a seal for the Society from a design by Cipriani, modelled by Spang, and Spang was rewarded for his model. This seal was used for many years, and when the Society was incorporated it was adopted as the Corporate seal until it was abandoned for the vastly inferior design now employed. It also

served at one time for the heading of a book-plate for the books purchased under the bequest left in 1797 by W. B. Earle.

There were also a few other awards for medals about this time. One to G. M. Moser (the first Keeper of the Royal Academy) for a medal for the Society, which does not seem to have ever been adopted; two to his nephew, Joseph Moser, in 1762 and 1763; and two to John Taylor, afterwards a jeweller at Bath, for allegorical designs.

After the date when these prizes were awarded, the subject of die-engraving dropped out of the Society's lists. Indeed, the last offer of a prize for medals appears in the list for 1765; though prizes for wax models for medallions were continued to 1770. It was one of these that Lewis Pingo obtained in 1772, and it was many years before attention was again given to the art of the medallist. Indeed, it is not until 1807 that an offer of a premium for medal die-engraving again appears, and then it does not seem to have attracted much attention. In 1817 George Mills, a medallist of repute at the time, received a gold medal for a medal die, and he followed up this success by obtaining similar awards in 1818 and in 1828, the last prize being for a new die for the Society's Vulcan medal. From 1813 to 1820 a number of gold medals were taken by members of the Wyon family, several of them for medals for the Society. Details of all of these will be found in the list

* The four medals for Belleisle, Minden, Guadaloupe, and Plassy, are in the possession of the Society.

Hosted by Google

published in the last number of the *Journal*.* The name of Pinches appears in the list for the years 1836 and 1837, when silver medals were awarded to T. R. Pinches for medal dies, and Scipio Clint, the son of George Clint, A.R.A., the engraver, received gold medals for dies in 1824 and 1825.

It seems not unreasonable to assume that the revival of gem-engraving, which occurred in the latter part of the eighteenth century, was due, to a large extent, and perhaps entirely, to the Society of Arts. In 1759 a prize of ten guineas was offered for an intaglio on red cornelian, and it is stated that the prize was offered because, although "the Art of Engraving in Gems is a ~~very~~ ~~ancient,~~ ~~useful~~ and curious Art, and has always been esteemed, yet [it] is but little practised in this nation." The age of the candidates was limited to twenty-six. The prize was taken in 1760 by Thomas Smith, jun., for an engraving of the Meleager. In the following year the age of the candidates was reduced to twenty-four, and the prize was taken (1761) by Nathaniel Marchant, then a young man of twenty-one.

In the list of prizes issued in 1761 the age was again raised to twenty-six. This prize was taken by Edward Burch. Both Marchant and Burch became Royal Academicians, and were undoubtedly the finest gem-engravers of their day. Mr. Cecil Thomas, a most competent authority, expresses a preference for the work of the younger artist. "Marchant was easily the foremost, many of his figure-subjects being admirable and delicate examples of intaglio engraving." †

The offer of prizes was continued down to about 1770, the conditions being varied from time to time, and separate prizes being added for cameo-cutting. In the 1762 list there is no age limit. During the ten years or so for which prizes were offered Marchant took six, Burch three, Nehemiah Spicer four, Robert Staples four, John Fruin two, and Lewis Pingo one.

Cordial testimony to the value of the help given by the Society to the encouragement of gem-engraving is borne by Burch himself, who says in his catalogue of engraved gems :—

"The first step of lifting the arts from obscurity may justly be ascribed to that truly laudable and patriotic Society for the Promotion and Encouragement of Arts, Manufactures and Commerce; the Duke of Richmond's Gallery; with a valuable collection of gesses from the most admired figures and busts of the antique; and the Artists' Subscription Academy for studying after Nature. If we take these collectively, we shall there find an ample field for encouragement and improvement. First, the above honorable society who gave (with a liberal hand) premiums for history paintings, large and small models for sculpture likewise, and engravings on gems; and it is with thankfulness that I acknowledge the share I had in these honours and emoluments. Premiums were also given for engravings on copper-plate, drawings in various branches; in short, what was most for the fame and opulence of their native country was generously undertaken by them, and carried on with a spirit which must do honour to any institution."*

In the same year (1759) in which the prize for gem-engraving was first offered, a prize was also proposed for "casts or impressions in glass, commonly called pastes," "nearest in excellence to antique pastes, as well cameos as intaglios." The offer was continued in successive lists up to 1764, and after this occasionally prizes were offered for cameos and intaglios. It did not produce very much result. Two awards of twenty guineas each were made to Samuel More, afterwards Secretary to the Society and then a member, in 1763 and 1764 for two collections of such impressions, and in 1765 premiums of ten and five guineas were given to Edward Carter, a jeweller, and to Robert Fruin, a gem-engraver. No information about these imitation cameos seems to be available. Of more interest and importance is the award of ten guineas in 1767 to James Tassie for "Figures, head and portraits of his composition resembling antique onyx." Tassie soon acquired a considerable reputation, both for his copies of ancient gems and for portrait cameos modelled by himself. The paste was, according to an analysis by Professor Crum-Brown, "a very easily fusible glass, essentially a lead potash glass," and as it was reduced by a very moderate heat to a pasty consistency, it was admirably suited for taking casts from moulds of plaster or other material.† Tassie was not only a competent chemist, but a skilful modeller, and he eventually established a considerable business, which, after his death in 1799, was carried on by his nephew William. His portrait medallions and reproductions were highly appreciated, and Mr. Gray, in his memoir, quotes a letter from Shelley to Thomas Love Peacock, in 1822, asking Peacock "to get me two pounds' worth of Tassie's gems, in Leicester Square, the prettiest, according to your taste." At the

present time his works are of value. There is a collection of them in the possession of the Edinburgh Board of Manufacturers. Miss Catherine Andras, who received a silver palette in 1801 for her portrait-models in wax of the Princess Charlotte and Lord Nelson, is thought by Mr. Gray to have been connected with the Tassies, as some of her models were cast in their paste by them.

For a long period the subject of gem-engraving was quite neglected by the Society, so far as the offer of prizes was concerned. The subject reappears in the premium list for 1823, and from that date on prizes were occasionally given. In 1828 a gold medal was presented to C. Durham for an intaglio, and a silver medal to J. S. Phillips for a cameo. F. F. Cuisset took silver medals for intaglio in 1830 and 1832. Nothing more has been discovered about these artists' work, and their names do not appear in Forrer's Dictionary.

A gold medal was awarded in 1827 to William Warner for an intaglio of a group (Mare and Foal) which has been preserved, and is a nice piece of work. He was a seal engraver established in London, who afterwards cut some seals for Queen Victoria and the Prince Consort, as well as some medallion portraits of Napoleon III. and the Duke of Wellington. The last award which requires mention is a gold medal in 1845 to T. Moring, for an engraving on white cornelian. This is still in existence, and the writer has an impression of it.

A very important service rendered by the Society to the promotion of the Fine Arts in England, was the establishment of periodical exhibitions of the works of contemporary artists, since it was directly as a consequence of those exhibitions that the Royal Academy was founded. The Society, therefore, may legitimately claim to have been not only the precursor of the Academy, but the original source from which that great institution was developed.

That English artists should never before have adopted this method of making their works known to the public is the more extraordinary, because it had long been well known and popular in Paris. Exhibitions of contemporary pictures had been held regularly in France a century before the idea was started in this country. As a French writer on the subject says: "C'est à la France que revient l'honneur d'avoir institué les expositions périodiques des artists vivants." On the advice of Colbert, Louis XIV. suggested to his Academy of Painting and Sculpture that its members should hold an annual exhibition of their works. The proposal was accepted in 1663, though it was not till 1667 that the first Salon des Beaux Arts was opened. By the advice of Colbert the exhibition was made biennial instead of annual, and from that time it has been continued, with certain short intervals and occasional irregularities, at first biennially and afterwards annually, down to the present day. There is no need to follow the history of these exhibitions. Those who wish to do so will find an excellent account, succinct, but with full detail, in Larousse's well-known Dictionary,* from which source the above particulars are taken. Mention may, however, be made of Diderot's studies on the Salons from 1759 to 1781, collected and published in 1796, and afterwards included in a more complete form in the edition of Diderot's works, edited by Mons. Assèzat.† It does not look as if many English artists contributed to any of these Salons. The only English name mentioned by Diderot is that of Strange, the engraver.

There seems reason to believe that the idea of holding an exhibition of pictures in London was suggested by the popularity obtained by the collection of pictures at the Foundling Hospital. This collection was formed by the liberality of various artists, who contributed pictures for the decoration of the walls of the new building of the hospital, Hogarth being a principal donor, and the most eminent among the contributors. According to the statement in Austin Dobson's "Life of Hogarth," which is corroborated by information in Brownlow's account of the Foundling, the collection was formed about 1746. It soon became a popular resort, and the artists who had given the pictures found a good deal of benefit from the advertisement, though there was no actual profit, as nothing was charged for admission.

The very moderate publicity thus given to the pictures of a few artists seems to have suggested the idea that an exhibition on a larger scale would be highly profitable, by attracting the attention of the public and giving artists generally an opportunity of making their works known. At any rate, it is certain that, whether in consequence of the Foundling collection or not, a committee of artists was formed, in 1759 or 1760, at the "St. Martin's Lane Academy"—the well-known painting school previously referred to in these notes—with the object of promoting the formation of a regular exhibition

of paintings. Of this committee, Mr. Francis Hayman, an active member of the Society of Arts, and afterwards an original Royal Academician, was chairman.

The Society had moved into its new premises opposite Beaufort Buildings in 1759,* and one of the reasons for its move was the acquisition of a "Great Room," in which could be exhibited the pictures and other works of Art to which its premiums had been awarded. It had, therefore, facilities for holding an exhibition on a large scale (the Great Room was 80 ft. by 40 ft.), and had already held exhibitions of a less important character. Hayman, therefore, very naturally appealed to the Society for its aid.

This he did by making a formal application, since it appears from the minutes of the Society of Arts that on February 27th, 1760, "A letter from Mr. Francis Hayman, Chairman of the Committee of Artists, was read, desiring the use of the Society's room for exhibiting paintings, etc." The letter was referred to a large and important committee, including among its members, Israel Wilkes, R. E. Pine, Sir George Savile, Lord Ward, P. Carteret Webb, Mr. Chambers, Lord Middleton, Sir Thomas Robinson, Thomas Hollis, Dr. Knight, and Henry Baker. The committee reported on March 5th that "they are of opinion that the Society may allow a Public Exhibition of Productions in the Polite Arts for one fortnight this year under such regulations and restrictions as the Society shall hereafter prescribe."†

Regulations were accordingly prepared, under which all pictures sent in by the committee of artists were to be accepted, all other pictures being selected by a committee of the Society. The Society's committee was to be the hanging committee, and to "appoint the places where all the productions may be hung or exhibited, in case any dispute shall arise among the artists about placing them." No charge was to be made for admission.

It is quite clear that, although the Society accepted the proposition of the artists for an exhibition, they took care to reserve to themselves all the arrangements—so that it was, in fact, the Society's exhibition. All the costs and charges were borne by the Society, and it appears from the account books that though they paid all the expenses, they received nothing whatever in return. More than this, the Society's committee were responsible for all the details of the arrangements, the printing of the tickets, the preparation of the catalogue, etc. Pictures sent in by the committee of artists were accepted, but that was all they had to do with the management of the exhibition.

In the exhibition there were 130 pictures by sixty-nine painters. The best artists were well represented. Reynolds had four portraits, Richard Wilson three landscapes, Hayman his well-known picture of Garrick as Richard III., and Cosway the portrait of Shipley. Among other important exhibitors may be mentioned Highmore, Morland, Pine, Sandby, Carlini, Moser, Pingo, Roubiliac, Wilton, MacArdell, Gwynn, Rooker, Strange, and Woollett. The title of the catalogue, which was sold for sixpence, was "A Catalogue of the Pictures, Sculptures, Models, Drawings, Prints, &c., of the present Artists, exhibited at the Great Room of the Society for the Encouragement of Arts, Manufactures, and Commerce, on the 21 of April, 1760."

The exhibition was a success, but, unfortunately, a success which led to disaster, for a disagreement arose among the exhibitors as to the use to be made of the money received at the door in exchange for catalogues. This amounted to one hundred pounds, and the money was, apparently, left to the disposal of the contributors. The Society certainly never had or asked for any of it. It appears to have been invested, and was probably added to the fund devoted, as is mentioned later, to charitable purposes. In consequence of the dispute there were two rival exhibitions in 1761. The chief artists seceded, and formed themselves into the Society of Artists of Great Britain, which exhibited in Spring Gardens, and the Society of Arts continued its patronage to the others, who subsequently styled themselves the Free Society of Artists. Each body took credit for the exhibition of 1760, and counted its own exhibition of 1761 as the second.

The Society's exhibitions were continued for four more years—1761 to 1764—and they were principally supported by those artists who eventually became the Free Society of Artists. These exhibitions all seem to have been well supported. But the artists who contributed, although distinguished, were neither so numerous nor so important as those who had seceded, and who contributed to the rival exhibition of the Society of Artists of Great Britain.

It was definitely decided, and notices were

* See *Journal*, September 22nd, 1911.

† This account of the Society's early exhibitions of pictures has been somewhat condensed from the article by Mr. H. B. Wheatley in the *Journal*, September 6th, 1895. The rather fuller details contained in that article are very interesting, and it will well repay perusal.

Hosted by Google

printed on the catalogues, that the money arising from the sale of the catalogues, which formed the only profits of the exhibition, was to be given "by the artists immediately after the exhibition to some public charity." There seems to have been a certain amount of trouble in consequence of the numbers who came in, as no admission fee was charged, and it was found necessary to employ a number of constables to control the crowd.

After 1764 the Society decided to discontinue the exhibitions, but the artists held exhibitions in 1765 and 1766, in "Mr. Moreing's Great Room in Maiden Lane, Covent Garden." In 1767 the Free Society of Artists was definitely formed, and they held annual exhibitions up to 1783—first in "the two new Great Exhibition Rooms in the Pall Mall, near the bottom of Hay Market," then in "Mr. Christie's new Great Room, next Cumberland House, Pall Mall,"* and after this, in rooms in or near the Haymarket.

The "Society of Artists of Great Britain," on leaving the Society of Arts, went to "the Great Room in Spring Garden, Charing Cross." It is not quite certain where this room was situated, but it is supposed to be now incorporated in the offices of the London County Council. As previously stated, the chief cause of the split among the artists was a dispute as to the use to be made of the money obtained from the sale of the catalogues; but it is evident that the ruling of the Society of Arts, that no charge should be made for admission, had much to do with the decision of the chief artists to go elsewhere, for in the preface of the catalogue of the Society of Artists for 1762, which was written by Dr. Johnson, we read:—

"Of the price put upon this exhibition some account may be demanded. Whosoever sets his work to be shewn naturally desires a multitude of spectators, but his desire defeats its own end when spectators assemble in such numbers as to obstruct one another. Though we are far from wishing to diminish the pleasures or depreciate the sentiments of any class of the community, we know, however, what every one knows, that all cannot be judges or purchasers of works of art, yet we have already found by experience that all are desirous to see an exhibition. When the terms of admission were low, our room was throng'd with such multitudes as made access dangerous, and frightened away those whose approbation was most desired."

These remarks form a curious commentary on the precautions found necessary by the Society of Arts, which have been previously alluded to. They also show how highly popular these newly established exhibitions became.

The exhibition of the Society of Artists of Great Britain for 1761 is styled on the catalogue "the second year," but no explanation of the secession from the exhibition of the Society of Arts is made. This catalogue contains a frontispiece by Hogarth, representing Britannia as watering the roots of three trees, labelled respectively painting, sculpture, and architecture, from a fountain surmounted by a bust of George III. Hogarth himself exhibited no less than seven pictures, among which were his celebrated "Sigismunda," the "Gate of Calais," "Picquet, or Virtue in Danger," and "The Election." Gainsborough sent a portrait, Reynolds five portraits, Richard Wilson six landscapes, and Francis Hayman a picture of "Sir John Falstaff." The receipts from this exhibition were £650.

The Society of Artists of Great Britain obtained a Charter and a coat of arms in 1765, and became known as the Incorporated Society of Artists. George Lambert was appointed the first president, Francis Hayman the first vice-president, and F. M. Newton the first secretary. The Incorporated Society seemed to be on the high road to prosperity, but, in spite of complaints, it did nothing for teaching, and formed no school, so that many of the leading artists became disgusted, and again there was a secession. The seceders applied for a charter for an academy, which was granted, and the Royal Academy was founded in 1768. From that date the Incorporated Society steadily declined, although, for a time, some of the Royal Academicians continued to send to its exhibitions.

The exhibitions of the Incorporated Society continued to be held in Spring Gardens until 1771. In the following year the Society removed to their "new room near Exeter Exchange," which was on the site of what is now the Lyceum Theatre. In 1777 the Society went to Piccadilly, near Air Street; in 1780 to Spring Gardens, and in 1783 to Exeter Exchange again. No exhibition was held between 1783 and 1790, when a final exhibition was held, and after this the Incorporated Society came to an end.

For at least fourteen years previously various proposals had been made in different quarters for the formation of an Academy of Arts. Soon after the Society of Arts had been established, a suggestion was considered that the Society itself should apply for a charter for an Academy of Painting, Sculpture, etc. The principal advocate

* Cumberland House was afterwards part of the War Office, and was pulled down when the Automobile Club was built in 1910.

Hosted by Google

of the scheme was Henry Cheere (afterwards Sir Henry Cheere), and he was warmly supported by Dr. Madden. The full text of his proposal, with the draft of a charter for a Royal Academy, is preserved in Dr. Templeman's MS. volume of *Transactions* previously referred to. The proposal, however, was not approved, and the Society even refused to offer one of its prizes for a scheme for such an Academy.

Even before the establishment of the Society a definite proposal for an Academy of Fine Arts had been put forward. In 1753, a number of artists, under the chairmanship of Francis Hayman, actually held a meeting to discuss the project. The official notification of the meeting, held on November 13th, is as follows :—

"There is a scheme on foot for creating a public Academy for the improvement of painting, sculpture, and architecture, and it is thought necessary to have a certain number of professors with proper authority in order to making regulations, taking subscriptions, etc., erecting a building, instructing the students, and concerting all such measures as shall be afterwards thought necessary. Your company is desired at the Turk's Head, in Gerard Street, Soho, on the 13th November, at five in the evening, to proceed to the election of thirteen painters, three sculptors, one chaser, two engravers, and two architects, in all twenty-four, for the purpose aforesaid (*signed*), Francis Milner Newton, *Secretary*." *

No agreement was come to at the meeting, and the projectors were satirised by their fellow artists, and became the objects of several caricatures.

The reason why these proposals all failed, and why the Royal Academy succeeded, was, as has been pointed out by Messrs. Hodgson and Eaton in their "History of the Royal Academy," that its projectors had realised that there was a source of revenue in the holding of exhibitions of pictures. The hundred pounds taken at the Society's first exhibition proved that, and further confirmation was provided by the larger receipts at those exhibitions when a charge was made for admission. The founders of the Royal Academy made good use of their experience, and from their day to our own the Academy has earned much money by its exhibitions, and has applied that money wisely and well to the education of artists.

It is interesting to note that while the constitution of the Academy, as defined in the "Instrument" or charter, granted by George III., is entirely different from that proposed in the scheme for an Academy of Painting submitted to the Society in 1755 by Sir Henry Cheere, its objects, and the methods of attaining them, are identical with those set forth in the original proposal. Those who drafted the older scheme evidently had in their minds the establishment of an institution similar to the Royal Society. Their Academy was to consist of an unlimited number of Fellows with a president and a council, whereas the founders of the Royal Academy took for their model the French Academy of Louis XIV. with its forty members, the governing body being a council of eight, on which all Academicians served in rotation. When, however, they came to details, they practically adopted the scheme set out in Cheere's draft charter, which proposed an annual exhibition, the appointment of professors (anatomy, geometry, perspective, architecture, antiquity, and "other studies"), and a drawing-master, the establishment of a school with models, the provision of medals, etc. Practically the same establishment is provided in the "Instrument," which, though obsolete in some particulars and modified in others, is still the fundamental charter of the Academy.

Had the original proposal been carried out, there can be little doubt that the Society would have been merged in the Academy, which would almost certainly have developed on its present lines. It is, therefore, probable that much of the useful work carried out by the Society in the first half century of its existence would never have been accomplished, and it is highly unlikely that any improvement would have been effected in the methods of the Academy. Probably the net result would have been that Art would not have benefited, while agriculture, invention, industry and commerce would, for a time at least, have suffered. So while the Society of Arts may take a legitimate pride in the share it had in preparing the way for the establishment of the Royal Academy, it may also congratulate itself on the fact that the attempt to concentrate in the hands of a single institution the work of supervising and promoting all the arts and industries of the country did not succeed.

* Rimbault's "Soho" (1895), pp. 194, 195, quoted by Mr. H. B. Wheatley.

MEXICAN FIBRE-PRODUCING PLANTS.

A great variety of fibre-producing plants, which could be utilised in the manufacture of cordage and kindred industries, are to be found growing wild in the State of Tabasco, Mexico, but their proper classification, and the numerous uses to which they can be applied, have been ignored,

Hosted by Google

In the municipalities of Cardenas, Comalcalco, Paraiso, and Nacajuca, extensive tracts of land are covered with an exuberant growth of the pita plant. Possibly, with the exception of ramie, the pita produces the finest fibre of all textile plants. It is said that, although its weight is one-fourth that of hemp, its tensile strength is fully three to four times greater, and its qualities are not impaired by exposure to the severest weather or immersion in water. Its fibre is glossy white with a silken sheen, and it could no doubt be utilised in the manufacture of linen cloth. Paper manufactured from this fibre has a beautiful white, smooth surface, and is of greater strength and lasting qualities than linen paper. The pita leaves are eight to twelve feet long and about two to three inches broad, gradually tapering to a switch-like point. It is stated that about ninety leaves will produce two pounds of fibre, and that the leaves from each plant can be removed at least three times during the year, each plant producing two to three pounds of fibre annually. In rich soil the pita plant will reach full development in two years. It thrives best in low, wet lands under dense shade, where water is constantly evaporated instead of becoming stagnant. The American Consul at Frontera says that, at present, this fibre can be obtained only in small quantities, owing to primitive processes employed by the Indians in its extraction. They place the long slender leaves on a smooth board in a slanting position, and with the thin edge of a rib of a horse or cow, which they select as nearly semi-circular as possible, remove the pulp from both surfaces of the leaf. The fibre is then dried in the sun, and after a short exposure becomes beautifully white and glossy. The Indians dwelling on the border of the States of Tabasco and Chiapas manufacture hats and reticules with this fibre, which are exceedingly fine. The women occasionally manufacture handkerchiefs equal in appearance to the finest linen. During an inspection of the woodlands in the immediate vicinity of Frontera about two years ago, for the purpose of obtaining data relative to the textile plants of the State, a fibre-producing plant was found, the exact name of which could not be ascertained. A small plant was transplanted in the garden of the American Consul at Frontera, and has developed into a vigorous plant, the leaves now being four feet long and three to four inches wide. Their formation is quite similar to the sisal leaves of the Yucatan and zapupe of Tuxpam, State of Vera Cruz, having, like these leaves, a sharp, needle-like spike at their tips; but, unlike zapupe or sisal, they have no spines along either edge, which is a great advantage, as it takes a long time to remove them. Natives state that this plant is known as an agave. The fibre of this plant is superior to zapupe or sisal, and, while not as fine as the pita, it possesses, to a certain extent, many of its qualities. If properly cultivated, it would, it is said, undoubtedly produce a valuable fibre for commercial purposes, and could be produced in enormous quantities on the rich lands of the State of Tabasco. Numerous other textile plants are found in the forests of Tabasco, such as the ramie, chimbombo, various species of the agave, and jolocin, which forms the inside tissue that is attached to the wood proper and outside bark of the jolocin tree. It is employed by the Indians in making bagging and ropes, and when roughly twisted in several strands is used by them as traces for their carts or as girths for saddles.

OBITUARY.

Shadworth Hollway Hodgson, LL.D., F.B.A. —Mr. Shadworth H. Hodgson died at his rooms in Conduit Street on the 13th inst., at the age of seventy-nine. He was educated at Rugby and Corpus Christi College, Oxford, of which, at the time of his death, he was an Honorary Fellow. Being left a widower in 1858, after only three years of married life, he devoted himself, with increasing zeal, to the study of philosophy. His first work of importance was "Time and Space, a Metaphysical Essay," published in 1865; and this was followed by "Principles of Reform in the Suffrage" (1866), "The Theory of Practice" (1870), "The Philosophy of Reflection" (1878), "Outcast Essays and Verse Translations" (1881), and "The Metaphysic of Experience," his *magnum opus*, which was completed in four volumes in 1898.

Though Mr. Hodgson's writings naturally did not appeal much to the general public, they were eagerly appreciated by all serious students of philosophy. He was a man of immense learning, with a first-hand knowledge of practically every philosophical work, ancient and modern. The first president of the Aristotelian Society, he continued to frequent its meetings until a few months before his death. He received the honorary degree of LL.D. from the University of Edinburgh, and he was a corresponding member of the French Academy of Moral Science, and a Fellow of the British Academy. He joined the Royal Society of Arts in 1871.

John Godfree Single, M.Inst.C.E.—Information has been received of the death of Mr. John Godfree Single, which took place at his residence in his native town, Plymouth, on April 17th. Mr. Single was born in 1846. He went out to India in 1869, and served as executive engineer in H.M. Public Works Department, his duties being to a large extent concerned with the banks of the Indus. He took great interest in military matters, and at one time was Captain Commanding the Sukkur Detachment of the Sind Rifle Corps (Volunteers). Since his retirement, some twenty years ago, he resided in Plymouth. He became a member of the Royal Society of Arts in 1881.

GENERAL NOTES.

COTTON IN INDIA.—The report on the progress of agriculture in India for 1910-11 contains an interesting section on the cotton crop. Owing to the steady spread of the cotton-boll weevil in America, and the general increase in the demand for cotton, the importance of India as a grower for the world's markets has been brought into great prominence. Systematic efforts are therefore being made by the Agricultural Department to improve both the quality and the quantity of the staple. In Madras the improvements have taken two lines: one, the separation and selection of the best indigenous variety, resulting in the spread of the improved local species called *Karungani;* the other, the introduction of *Cambodia,* which ranks in quality with the best American cotton, and is suitable for the Liverpool market. Its yield per acre is four to five times as great as that of the indigenous cottons; it is expected that it will soon be found in every part of the country, and that it will revolutionise the Indian cotton industry. The crop last year was 33,000 bales, valued at Rs. 60,00,000. Most of this out-turn has been taken over at full prices by mills in Madras which are weaving with it a quality of cloth never before woven by machinery in India; while one firm alone last year shipped 10,000 bales direct to Liverpool. Good progress in the improvement of cotton has also been made in the Central Provinces. There are now 100 cotton-seed farms in Berar alone, covering an area of some 4,000 acres, and capable of producing 1,000,000 lbs. of pure seed per annum for distribution to growers. These farms do not belong to Government, though the work is controlled and supervised by officers of the department. They are owned by land-holders who have been induced by the authorities to grow pure seed of improved varieties for supply to cultivators.

THE NEW SCIENCE MUSEUM.—The report just issued by the Departmental Committee on the Science Museum and the Geological Museum, shows that considerable progress has been made in connection with the plans of the new building. The site lies between the Natural History Museum in Cromwell Road and the Imperial College of Science and Technology in Imperial Institute Road, its length from east to west being 1,150 feet. It will have a frontage of some 190 feet in Exhibition Road, and another of some 170 feet in Queen's Gate. At the two ends it is proposed to build large halls with surrounding galleries, which will make full use of the space, and form suitable accommodation for exhibiting the collections effectively. The central portion "may well be occupied by lofty buildings, such as would be required to enclose a hall worthy of its place in the centre of the Museum"; and this central hall will be connected with the east and west halls by comparatively low side-lit galleries. The complete scheme of the building for the Science Museum provides 377,000 square feet of floor space. The building for the Geological Museum, which will occupy a site east of the Natural History Museum, and between it and Exhibition Road, will provide about 80,000 square feet of floor space.

EXHIBITION OF IRRIGATION AT VERCELLI.—It is announced that an exhibition of irrigation and rice culture will be held at Vercelli next autumn, from October 10th to November 10th. This exhibition will embrace all subjects connected with the cultivation of rice and its preparation for the market. The irrigation department will include the following nine subdivisions, viz.: Head works and intakes, dams, artesian wells, mechanical appliances for irrigation, methods and appliances for the measurement of water, appliances for raising water, reservoirs and storage of water, co-operative societies for irrigation, monographs on irrigation. Situated half-way between Turin and Milan—the classical land of Italian irrigation—the town of Vercelli is most favourably placed for visiting many important works of the kind, including the Cavour Canal opened in 1866, by means of which the fertilising waters from the river Po are brought to the land.

COMMERCE OF THE ISLAND OF RHODES.—No time has been lost since the occupation of Rhodes by the Italians in promoting and encouraging the trade between the island and Italy. Much information on the subject has been collected by the Civil authorities, and, for the guidance of manufacturers and merchants at home, a list of the names of the principal trades and the chief articles in demand has just been published by a leading commercial journal, *Il Sole,* of Milan. From this it appears that, whilst some of the most important island firms send their orders direct to Italy or other European countries, the majority obtain their goods through agents established at Constantinople or in other commercial cities in Turkey. A few of the principal firms in Rhodes supply the retail dealers in the other islands of the Archipelago, as well as in some of the principal towns in Anatolia. The list contains the names of about twenty retail traders in Rhodes who are supplied by the local wholesale firms as well as by other firms in Turkey. Amongst the principal goods which find a ready market at Rhodes may be mentioned:—cotton and woollen manufactured goods, rope and cordage, yarn, glass, crockery and earthenware, mirrors, furniture, caps, haberdashery, sewing cotton, enamelled ware, hardware, ironmongery, drugs, sulphur, matches, etc., preserved food in tins, coffee, sugar, butter, cheese, flour, beer, soap, candles, paint, varnish, etc. An import duty of 11 per cent. *ad valorem* is levied by the Government on all goods introduced into the island. Amongst the principal exports may be mentioned dried figs, sesame, almonds, and carobs.

Journal of the Royal Society of Arts.

No. 3,110. VOL. LX.

FRIDAY, JUNE 28, 1912.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C.

PROCEEDINGS OF THE SOCIETY.

ANNUAL GENERAL MEETING.

The one hundred and fifty-eighth Annual General Meeting for receiving the Report of the Council, and the Treasurers' Statement of Receipts and Payments during the past year, and also for the Election of Officers and New Members, was held in accordance with the By-laws on Wednesday last, June 26th, at 4 p.m., LORD SANDERSON, G.C.B., K.C.M.G., Chairman of the Council, in the chair.

The SECRETARY read the notice convening the meeting, and the Minutes of the last Annual Meeting.

The following candidates were proposed, balloted for, and duly elected members of the Society:—

Abraham, Edward A. V., America-street, Georgetown, Demerara, British Guiana.

Ahmad, Maulavi Sayyid Makbûl, M.R.A.S., Fatehgarh, United Provinces, India.

Banks, Alexander, A.M.I.Mech.E., Manganese Bronze and Brass Company, St. George's Wharf, Deptford, S.E.

Brigstocke, Arthur Montagu, I.C.S., Lahore, Punjab, India.

Carter, Leslie, Warren Cottage, near Ashington, Sussex; and 26, Steele's-road, Haverstock-hill, N.W.

Chipperfield, Walter, Roneo Works, Romford, Essex.

Clench, Edward Claude Shakespeare, The Aster Engineering Company, Wembley, Middlesex.

Evans, William Steward, P.O. Box 274, Bloemfontein, Orange River Colony, South Africa.

Exley, J. R. G., A.R.C.A., A.R.E., Lugano, Hills-road, Cambridge.

Hatton, James, A.M.I.Mech.E., 49, Jesmond Dene-road, Jesmond, Newcastle-on-Tyne.

Hill, Harold, 322, Blackburn-road, Bolton.

Howard, John, 43, Garden Reach, Calcutta, India.

Khan, Khan Bahadur Habibur Rahman, Indian Telegraph Department, Quetta, Baluchistan, India.

Kwegyir-Aggrey, Professor J. E., M.A., Livingstone College, Salisbury, North Carolina, U.S.A.

MacDonald, Miss Eleanor, The Fort, Fort Qu'Appelle, Saskatchewan, Canada.

Mills, Sidney Carton, 24, Hillside-road, Stamford-hill, N.

Osgood, Mrs. Irene, Guilsborough Hall, Northampton.

Pooley, Ernest Henry, M.A., LL.B., Drapers' Hall, Throgmorton-street, E.C.

Prashad, Rai Bahadur Ashtabhuja, Bansi Ditt, Basti, United Provinces, India.

Priestley, Neville, Roadside, 102, West-hill, East Putney, S.W.

Pulford, William Henry, 132, Clement's-road, East Ham, E.

Raymond, Professor George Lansing, 24, St. James'-park, Los Angeles, California, U.S.A.

Reindorf, Christian J., Accra, Gold Coast Colony, West Africa.

Riviere, Donald Osmund, Chambers, Roseau, Dominica, British West Indies.

Rosanoff, M. A., Sc.D., Clark University, Worcester, Massachusetts, U.S.A.

Smallbones, Robert Townsend, Loanda, Portuguese West Africa.

Smith, Henry, 24, Haymarket, S.W.

Speaker, Gustave Robert, 28, Mark-lane, E.C., and 71, Cadogan-place, S.W.

Stevens, George Nevill, Tapah, Perak, Federated Malay States.

Szymanowski, Konrad, A.M.I.Mech.E., 4, Wosnessenski-prospect, St. Petersburg, Russia.

Visram, A. Allidina, Mombasa, British East Africa.

Williams, Samuel Beckerleg, Penelvan, Roskear, Camborne, Cornwall.

The CHAIRMAN appointed Mr. Byron Brenan, C.M.G., and Mr. John Armstrong scrutineers, and declared the ballot open.

Hosted by Google

The SECRETARY then read the following—

REPORT OF COUNCIL.

I.—ORDINARY MEETINGS.

The subject which Lord Sanderson selected for the address with which, as Chairman of the Council, he commenced the session last November was "The Development of International Intercourse." He sketched very briefly this development, beginning with Egyptian and Babylonian records, and drew attention to the immensely accelerated progress which had taken place in the last century. Finally, he enforced the conclusions at which he arrived by a valuable table, showing the comparative growth of foreign trade during the past fifty years.

Among the papers which have been read at the Ordinary Meetings, the Society has been fortunate in securing even more than the usual number of papers dealing with recent applications of scientific investigation. The first of such papers was the one read by Mr. A. E. Berriman on Aeroplane Efficiency, in which the various questions relating to the development of the aeroplane were ably dealt with. The problems with which future constructors of aeroplanes have to deal are difficult and complicated, and it is certain that a vast amount of experimental investigation is yet necessary. Mr. Berriman's communication to the Society was a valuable contribution to the theory on which such experimental investigation will have to be based.

The next paper which may be treated as belonging to the same category was that read by Professor G. W. Osborn Howe on "Recent Progress in Radio-Telegraphy." Here, again, we had a valuable paper dealing with the theory of an extremely difficult subject, though Professor Howe treated his material in a less technical fashion than Mr. Berriman, and succeeded in explaining satisfactorily to a non-specialised audience the principles of wireless telegraphy.

In their joint paper on "The Influence of Ozone in Ventilation," Dr. Leonard Hill and Mr. Martin Flack, who have been working on the subject in conjunction, succeeded in starting many novel ideas concerning a well-worn subject on which the Society has had many papers in previous sessions. Ozone is now being experimented with on a very large scale for ventilating purposes, and there seems every reason to expect that its application will be of considerable value. It is certain that it must be used with judgment, because its use in excessive quantities has a very great irritative effect on the human lungs and the whole respiratory tract.

The problem of illumination was dealt with a few years ago in an able course of Cantor lectures by Mr. Leon Gaster. In his paper on the subject Mr. Thorne Baker discussed the most recent sources of artificial illumination, and considered not only the question of the production of a light most nearly approaching daylight, but also the effect of the different artificial lights used, both in their technical applications and in their effect on human vision.

The last paper coming under this classification was the able communication by Mr. Ernest Kilburn Scott on "The Manufacture of Nitrates from the Atmosphere," which was read at the last meeting of the session. Mr. Scott was able to put forward an independent view of the two rival methods of producing artificial nitrates —the one now being conducted on a large scale in Norway, mainly as the result of the investigations of Professor Birkeland, and the methods for the production of cyanamide, which are for the most part at the present time carried on in Italy. Besides describing the methods of manufacture, and the already extensive applications of the products for the manufacture of artificial manures, Mr. Scott drew attention to their other uses, especially for the production of explosives. He pointed out that, whereas sodium nitrate is the most important ingredient in most modern explosives, gun-cotton, dynamite, and smokeless powders, there is at present no factory for its production in Great Britain, whilst there are factories on the Continent the whole of whose products are employed for the manufacture of explosives, and are taken over entirely by the Government of the country in which the material is produced.

The papers which came under the category of Applied Art were also of a very high class. Mr. Cyril Davenport, to whom the Society has been indebted in past years for many valuable communications, read an extremely interesting paper on Illuminated Manuscripts. As on previous occasions, the paper was illustrated with a very beautiful collection of lantern-slides painted by Mr. Davenport himself.

Mr. Cecil Thomas, in his paper, dealt with a subject in which the Society has always been deeply interested—that of Gem Engraving. The first prize for gem engraving was awarded by the Society in 1760, and for many years after this the prizes awarded did a good deal to encourage the progress in England of this very beautiful art. Mr. Thomas gave a

Hosted by Google

slight but sufficient sketch of the history of the subject, and this led up to an account of the present condition of the art, which, thanks to Mr. Thomas and a few other English artists, is now in an improving condition in this country; and it is to be hoped that the present revival of a very ancient and beautiful art will continue to progress.

The third paper dealing with matters of Art was the one read by Professor Ernest Gardner on Greek Sculpture. This admirable discourse was of purely archæological and artistic interest, and did not profess to have any application to modern industry, though the suggestions made in the paper, and the discussion as to the experimental reproduction of the most celebrated examples of chrys-elephantine statuary, may possibly produce practical results.

Mr. William Burton's paper on "Ancient Egyptian Ceramics" might not unreasonably be classed amongst those devoted to Industrial Art; but it is certainly more properly placed amongst those dealing with industry. It had an important archæological application, for, if his theory is correct, the specimens of pottery which have always been considered Egyptian are, according to his analysis, specimens of an art anterior to that of the potter, viz., that of glazing carved sandstone figures. His paper may throw light on the history of the origin itself.

Mr. Frank Warner, in his paper on the British Silk Industry, dealt with matters of a very different date, and so far from discussing questions of pre-historic art and manufacture, it was devoted entirely to the development of the industry during the past nine or ten years. It is satisfactory to be able to say that, in the opinion of so competent an authority, the silk industry of this country at the present time is, in spite of a good many difficulties, flourishing and prosperous.

Yet another industry, once a flourishing one and now revived, was dealt with by Mr. Theodore Salvesen in his paper on "The Whaling Industry of To-day." From the middle of the eighteenth to the middle of the nineteenth century the whale fishery was one of the important industries of the country, and one which the Society of Arts did not a little to assist by its encouragement of the gun-harpoon as a substitute for the hand-weapon. The whalers of Great Britain and the United States, however, followed their pursuit with such energy that the "Right Whale," which for long was esteemed the only one worth seeking, became so much diminished in numbers that it hardly paid to fit out vessels for its capture. Although whaling was continued mainly for the capture of the Cachalot, it had, at all events in this country, almost died out until it was recently resuscitated here and in Norway by an entire revolution of the methods adopted and a change in the animals sought for. The modern whaler, instead of starting for long voyages and remaining at sea until he has filled his hold with the products of his pursuit, now works from a station on land. He employs a small vessel, and tows his captured prey to the shore, where it is treated in such fashion that almost every part of the animal is rendered valuable for some product or another. He also, instead of pursuing the whale in boats with a hand-weapon, uses a gun of the same character as that rewarded years ago by the Society, but of a very different construction, and mounted on his steamer, with the result that the industry has been revived, and is now an extremely prosperous one, though how long it will be before it follows the fate of its predecessor is not very easy to foretell.

Mr. Martin Duncan's paper on the Marine Biological Association ought to be mentioned in succession to Mr. Salvesen's, because the work which the Association has done has had such an important bearing on British Fisheries, one of the greatest and most important of our industries.

Another paper may be classed as an industrial one, not because it dealt with any special industry, but because it gave an account of a process likely to be applicable to a good many industries—namely, the paper read by Mr. W. J. Gee, on his process for the Separation and Grading of Solids. If we may judge from the attention attracted to Mr. Gee's paper, and the correspondence which it involved, the process is likely to come into extensive application, and to prove of very great use.

Perhaps Mr. Yorath Lewis's paper, on what he terms "Continuous Passenger Transportation," may be classified with those dealing with industrial matters, because the question of the transportation of both passengers and goods is becoming one of pressing interest, almost it might be said of emergency, in relation to industry. Mr. Lewis described a scheme under which transportation in thickly-populated cities would be effected by means of underground or tube railways, on which trains would run continuously without actually stopping, but, while passing through the stations, slackening the speed sufficiently to allow the passengers to enter and leave the cars. The whole scheme has been thoroughly worked out by Mr. Lewis, and

Hosted by Google

the paper contains full information of all the necessary engineering details.

During the session three papers on educational subjects were read. The first of these was by Mr. H. A. Roberts, Secretary of the Cambridge University Appointments Board, which has been of such valuable service in assisting young graduates to find suitable opportunities for earning their living. Mr. Roberts's subject was "Education in Science as a Preparation for Industrial Work," and this precisely describes the scope of his paper, which was an excellent and forcible appeal on behalf of the educated graduate to those who are at the head of great industrial concerns. Mr. Roberts showed how much had already been done in utilising the services of young men with a sound scientific training, and pointed out how much there was yet left to be accomplished in this direction.

Another branch of the same subject was treated by Mr. J. H. Coste, in his paper entitled "Municipal Chemistry," for this, to a very large extent, dealt with the necessity for the employment of competent and qualified chemists in the great variety of work which is now coming into the hands of municipal corporations.

The other paper on Education was an excellent address by Mr. George Fletcher, Assistant Secretary of the Department of Agriculture and Technical Instruction for Ireland, on "Technical Education in Ireland." Mr. Fletcher gave a very full account of all that has been done in this direction, and indicated how much might be hoped with regard to the future prosperity of Ireland, if the work could be continued and developed on the same lines and to a greater extent.

Two papers, both read in the early part of the session, may be classed together as of a historical nature—Mr. James Douglas's account of "The Industrial Progress of the United States of America," and Mr. J. A. J. de Villiers's paper on "British Guiana and its Founder." Of the two Mr. de Villiers's was of purely archæological interest, while Mr. Douglas's dealt with the recent industrial progress of the States.

Only one more paper remains to be noted, and that was the attractive and brilliant account of British rule in Nigeria, which was given by Mr. E. D. Morel. Mr. Morel's articles in the *Times*, since republished as a book, gave a great deal of information, which, if not new to experts, was certainly not familiar even to the well-informed public, about the ancient negro and Arab civilisation which existed in the country now known as Northern Nigeria, and the French districts to the north of it, and also about the effect of modern colonisation and modern civilised influence, which has lately been brought into contact with the relics of the ancient civilisation which still existed in Kano and Timbuctu.

II.—Indian Section.

The story of the North-Eastern Frontier of India was told by Sir Thomas H. Holdich at one of the earlier meetings of the Section. After vividly describing the physical features of this remote corner of our Indian Empire, he referred to the proposed land connection with China and Burma. It is, he thinks, impossible to look to a long future without the conviction that India will eventually be linked by a railway "which will render a complete command of all contiguous tribes a political necessity." Of the three possible ways of entering Burma from India, he expressed a preference for that *via* the Hukong Valley, the great commercial possibilities of which were emphasised by Sir Eric Swayne, under whose direction this route was surveyed sixteen years ago. Sir George Scott (Shway Yoe), among others, took part in the discussion on Sir Thomas Holdich's singularly interesting paper.

The first-fruits of the Indian Census of last year were given to the Section by Mr. E. A. Gait, I.C.S., C.I.E., whose valuable paper, written in India, was read in the author's absence by Mr. J. D. Anderson. When, by desire of the Society, the Census Commissioner kindly prepared the paper, barely twelve months had elapsed since the census was taken. A portion of the final tables was still incomplete, and none of the provincial reports had been sent in. Consequently it was impossible for Mr. Gait to deal, as the writers of some of the Society's previous papers on Indian censuses have done, with certain branches of the subject, such as migration, caste, and occupation. Mr. Gait, therefore, confined himself in this preliminary survey to a presentation of the main features of the statistics and to a consideration of the broad conclusions to be drawn from them. The efficiency of his plans for taking the census was shown by the remarkable speed with which the provisional totals were got in. The results for the whole of India with its teeming population were received complete at headquarters within nine days and issued in print next morning, with full details not only for Provinces and "Agencies," but also for Districts and States and the principal towns. This, as Mr. Gait pointed out, constitutes a record. The Registrar-General (Mr.

Hosted by Google

Bernard Mallet, C.B.) took part in the discussion on the paper, and as the authority responsible for the recent census in England and Wales paid a tribute to Mr. Gait for the "splendid success of his vast undertaking." Sir Chichele Plowden, Census Commissioner in India in 1881, and Sir Athelstane Baines, who occupied the same position in 1891, also took part in the proceedings.

The tenth of the series of papers on the Provinces of India was read by Sir John O. Miller. His theme was the Central Provinces, of which he was Chief Commissioner a few years ago. He claimed that what was formerly sometimes called the "Cinderella of the Indian Provinces," has passed the stage at which it can be called backward, and that its people are preparing themselves to play their part in the industrial evolution of India. One of the most eminent of Sir John Miller's predecessors in the Central Provinces—Lord MacDonnell—presided, and the newly-appointed Chief Commissioner, Sir Benjamin Robertson, was one of the speakers. The *Pioneer*, in a recent leading article says:— "The Royal Society of Arts follow the useful practice of bringing the several Provinces of India under periodical review by means of papers contributed by distinguished Indian public servants, who can speak with knowledge and authority . . . We are gradually realising that the study of India as a whole is confusing and profitless, as the study of Europe as a whole would be. A country and not a continent is the preferable unit. There is much more to be learnt from placing one Province under the student's microscope, especially when the Province happens, as in the present case, to contain the contrasts and diversities which characterise India as a whole. Sir John Miller's paper would serve as an admirable introduction to the study of the aims and results of British administration in India."

Mr. Neville Priestley, in an important paper, gave a lucid history of the necessarily varied policy followed by the Government of India in regard to the financing of railways since their inception, and ably discussed the reasons why the opening of the country by means of new lines is at present "practically at a standstill." Owing to many pressing demands on the public purse, the supreme authorities are reduced in the current year to a "Construction Programme" of only fourteen miles (apart from extensions already in hand), and to another sixty or seventy miles from funds furnished by outside agencies, whereas, in Mr. Priestley's opinion, an expansion at the rate of a thousand miles a year is required. One of the remedies suggested in the paper is the making of lines of a less expensive character, a suggestion endorsed by the chairman of the meeting (the Right Hon. Sir Edgar Speyer), who, in the course of a weighty speech, pointed out that in the United States, where railway construction has proceeded in a very remarkable way during the last fifty years, the rule generally has been to build railways lightly, to trust to the development of the country, and later to use the surplus for the completion of the lines. He seemed to think that it might be an inducement to British capitalists, who hitherto have been inclined to ignore India as a field for investment, if, as an experiment, one of the existing lines could be taken over by a private company at a fair valuation and run entirely as a private concern. Everyone present, he added, appreciated the great importance of the subject, and, after listening to the paper, he felt tempted to give the matter more attention than he had done in the past. A most useful discussion followed.

In the autumn of 1908, Dr. Travis Jenkins, a well-known expert, went out to Calcutta to advise the Government of Bengal on fishery matters, and the excellent paper he read before the Section embodies the main results of the investigations conducted by him, at sea and inland, during his stay in India, lasting a year and a half. His experience has convinced him that India urgently needs a Fishery Board, to consist of five members representing the various maritime Provinces. It must, he says, be obvious even to anyone who has lived a very short time in India that its fisheries are neglected, and that it is the duty of the Government to encourage in every way in its power the development of a natural source of food supply, the potentialities of which are enormous.

The remaining paper was contributed by the Rev. Walter K. Firminger, the subject being "The Old District Records of Bengal." For the past five years Mr. Firminger has been engaged in a careful and disinterested study of these records, many of which are in a state of almost final decay. The late Sir W. W. Hunter drew attention to their importance as materials for history, but until recently scarcely any attempt seems to have been made to save the records from ruin. Mr. Firminger's description of what, through the liberality of the local Government, has been done with the records of Sylhet and Rangpur will, it is hoped, stimulate other

Hosted by Google

Provincial administrations to adopt similar measures.

III.—Colonial Section.

The series of papers on "The Manufactures of Greater Britain" having proved successful, it was decided at the time to institute another series of a similar character on the principal natural products of the oversea dominions and possessions. In 1909, Mr. A. E. Humphries dealt with wheat; in 1910, the Hon. Sir John McCall (Agent-General for Tasmania) with fruit generally; in 1911, Mr. F. Douglas Osborne with tin; and in the session just concluded Mr. Alan H. Burgoyne, M.P., with viticulture, which, it is believed, will become "one of the most noteworthy and striking industries under the British flag." Mr. Burgoyne's clever paper evoked a spirited discussion, in which some of his conclusions respecting South Africa were challenged by the Chairman (the Right Hon. Sir Walter F. Hely-Hutchinson) and the Trade Commissioner for the Union (Mr. C. du Plessis Chiappini). The interesting fact was mentioned that out of every dozen bottles of wine drunk in this country one bottle comes from Australia. The South African grower, on the other hand, caters more for the local market, apparently finding this more profitable than endeavouring to create an export trade.

Another question of importance to the Union of South Africa, namely, Irrigation, was discussed by Mr. W. A. Legg, M.Inst.C.E., at the meeting held on January 30th, under the presidency of the High Commissioner (the Hon. Sir Richard Solomon). How largely the agricultural future of South Africa must depend upon an adequate extension of its irrigation works is shown by the fact that the country, notwithstanding its extent, greater than the British Isles, France and Italy combined, is still obliged to import immense quantities of foodstuffs, amounting in value to millions of pounds annually. As Mr. Legg showed, the growing of crops with the rainfall alone without artificial watering can only be attempted in some of the more favoured portions of the Union, and these collectively do not form a large proportion of the whole. Much, however, is expected from the Irrigation Bill to be introduced by Mr. Botha's Government during the present session of the Union Parliament, and outlined by the High Commissioner in a forcible speech. Indeed, Sir Richard Solomon expressed the opinion that we may confidently look forward to the time when the Union will not only produce all the foodstuffs necessary for its own population, but will become one of the principal exporters of those articles to the European markets.

One of the merits of the paper read by the Hon. John Greeley Jenkins, on May 21st, is that it enables certain interesting comparisons to be made between railway expansion in the Commonwealth, and the somewhat disappointing state of things in India described by Mr. Neville Priestley a few days earlier. Railways were begun in both countries about the same time, but while Australia, with a population of four and a half millions, now possesses 17,000 miles of lines, India, with a population of 300 millions, has barely double that amount. Another noteworthy feature of the Australian railway system, and one that India is asked to copy as far as possible, is the cheapness of construction. In many States the cost has been less than £2,000 a mile; in West Australia one or two lines are believed to have been made for about £1,000 a mile, the average for the entire country being £9,000 a mile. Like India, Australia suffers from non-uniformity of gauge—there are three different gauges in the Commonwealth—but Mr. Jenkins and the Agent-General for Queensland (Sir Thomas Robinson) both declared that the disadvantages are not so great as is supposed by those unacquainted with the local circumstances. The Under-Secretary of State for the Colonies (Lord Emmott) expressed what seemed to be the general opinion of the meeting that while State-ownership of railways may not be feasible for the United Kingdom, at least within the next few years, Australia has fully justified her adoption of that principle.

An encouraging account of the condition and prospects of British North Borneo was given by Mr. Leonard Lovegrove, one of the officials of the Chartered Company who are administering with so much sagacity that distant Imperial possession. Earl Brassey, who presided, said that although North Borneo cannot be compared with the largest of Great Britain's tropical possessions, it is thoroughly typical of what our brethren are doing elsewhere beyond the sea. A pleasant feature of this meeting was the strikingly effective kinematographic pictures of scenes in Borneo shown by Mr. Cherry Kearton, who visited the island a year ago.

IV.—Cantor Lectures.

There have been five courses of Cantor lectures during the past session, and the subjects have been as varied as usual. The first course was by Professor Vivian Lewes on "The Carbonisation of Coal." In a course of four lectures,

Hosted by Google

Professor Lewes gave the whole history of the subject, and described the various methods which have been employed for obtaining from coal the largest amounts of the various products which can be obtained from it, while at the same time utilising, as far as possible, the energy available for the production of motive power. The earlier methods employed in the destructive distillation of coal were, of course, of a more or less crude nature. First of all, the idea was merely to obtain the largest amount of illuminating gas, but gradually the by-products, which it was found were valuable, became a very important consideration, and at the same time the question had to be considered of obtaining the resulting coke in such a form as to render it most useful. Professor Lewes's treatment of the subject was exhaustive, and brought the information down to the latest available point. It is satisfactory to know that the lectures attracted a great deal of attention amongst those interested in the gas industry. They were well attended by a large and attentive audience, and there has been a considerable demand for the reprint of the report of the lectures which appeared in the *Journal*.

The second course was by Dr. Vaughan Cornish, on the subject of Waves. It is to be remembered that the question is one not merely of scientific interest, but that the action of waves has a very practical engineering bearing in relation to such questions as harbour construction, the maintenance of river navigation, and coast erosion, to say nothing of the further question of the construction of embankments for railways and canals. Dr. Vaughan Cornish has given great attention to the theoretical side of the whole subject, and it may be hoped that the lectures which he has given here and elsewhere may be of practical value to the engineer and naval architect.

The third course, by Mr. Loudon Douglas, was devoted to the Meat Industry. The subject was treated in a very full and practical manner, and the three lectures were devoted respectively to the bullock, the sheep, and the pig, with the products obtainable from each.

The fourth course, by Mr. Luther Hooper, was devoted to the subject of Spinning and Weaving, the title being "The Loom and Spindle: Past, Present, and Future." The greater part of the course was devoted to the hand-loom, a machine which is by no means as obsolete as many may think, since it is still in extensive use, not only for domestic application, but for the manufacture of fabrics of a class and character which cannot be manufactured by machinery. The third and final lecture of the course was, however, devoted in large part to the power-loom, and concluded with a very interesting description of a new and modern type of loom, embodying entirely fresh principles, and differing entirely from the ordinary type, which, however much it has been modified and improved, is still of the same essential character as the oldest form of loom known to mankind.

The final course of lectures was by Mr. Noel Heaton, and was devoted to a description of "The Materials and Methods of Decorative Painting." The treatment was of necessity mainly historical, but Mr. Heaton included in the course a consideration of the most recent modifications of fresco, oil painting, tempera, etc.

V.—Howard Lectures.

In addition to the courses of Cantor lectures a course was given under the bequest of Thomas Howard. The lecturer was Captain H. Riall Sankey, and the subject, "Heavy Oil Engines." The lectures, in the main, dealt with the most recent form of internal-combustion engine—the Diesel heavy oil engine. The subject was treated in a very complete manner, the character and construction of the engine in its various types was fully described, and considerable stress was laid upon the important fact that the Diesel engine can employ oil of any character. The lecturer claimed that in its capacity for utilising almost any sort of oil, the Diesel engine had very great advantages over the earlier forms of the internal-combustion engine, which was very sensitive to the class of oil supplied to it. Many other important points were brought out, and on the whole the lectures gave a very clear and exhaustive account of what may be taken as the latest, though not necessarily the best, type of internal-combustion motor.

As not much is now remembered of the founder of the Trust, it may be well to mention that Thomas Howard was born in 1796. After being trained for the business of a manufacturing chemist, he devoted his attention more particularly to the chemistry of steam, with special regard to its employment in the steam engine. His first invention, in 1825, was a vapour engine, the object of which was to dispense with the then cumbrous boilers by injecting water upon a heated surface. In 1840 he joined the King and Queen Iron Works, of which he was senior partner at the time of his death in 1872. During

Hosted by Google

his connection with the works he introduced many improvements in the details of the machinery, and conducted many valuable experiments upon wrought iron.

Under his will the Society holds a sum of £500 for the purpose of providing prizes or medals for treatises on steam and other sources of motive power, or of rewarding inventors.

In 1884, the Council came to the conclusion that the best way of carrying into effect the wishes of the testator would be to arrange for the delivery under this trust of series of lectures on some subject dealing with motive power, which might, after their delivery, form a text-book on the subject. They have, therefore, from time to time, as the accumulated funds permitted, arranged for courses of Howard Lectures, dealing with subjects which seemed to be comprised within the terms of the bequest. Six such courses have already been delivered, and it is hoped that in future years these may be followed by others of equal value.

VI.—Juvenile Lectures.

A good many years ago Mr. Charles Vernon Boys delivered before the Royal Institution a course of lectures on Soap Bubbles, on which was founded his well-known book on the subject. Since the date of those lectures, Mr. Boys has been continually working at the same subject, and the lectures which he gave before this Society during the last Christmas holidays, while partly covering the same ground as the older series, introduced a great deal of fresh material which the lecturer has since accumulated—material which has involved the production of a new edition of "Soap Bubbles." There is no need to follow Mr. Boys through his course of two lectures, or to say how fully they were illustrated, and how greatly the experimental illustrations were appreciated by the audience.

VII.—Albert Medal.

The Albert Medal for the current session has been conferred, with the approval of H.R.H. the Duke of Connaught, President of the Society, upon the Right Hon. Lord Strathcona and Mount Royal, G.C.M.G., G.C.V.O., LL.D., D.C.L., F.R.S., "For his services in improving the railway communications, developing the resources, and promoting the commerce and industry of Canada and other parts of the British Empire."

In making this award the Council have desired to mark what they believe to be the national appreciation of the public services which Lord Strathcona has rendered, not only to the Dominion of Canada, but also to the whole Empire, public services which have now extended over a life of more than ninety years.

It is as the founder of the Canadian Pacific Railway that Lord Strathcona is best known to his contemporaries, and will be best remembered by posterity, for it was his energy and financial skill which enabled the project to be carried through at a time when there seemed little prospect of a successful result. The record of the services, social, political, and philanthropic, rendered by him to the country which he entered as a lad in the employment of the Hudson's Bay Company, is a very long one. He has been a munificent benefactor of such institutions as the McGill University and the Victoria Hospital at Montreal, erected by him in commemoration of Queen Victoria's Jubilee, and he has always been ready to provide for the needs alike of Canada and of the Empire, from the time when, during the Red River outbreak, he supplemented the forces of the Dominion with a troop of horse raised at his own cost, down to that of the Boer War, when he provided the entire cost of the corps of 600 mounted men, known as Strathcona's Horse, which was raised in Canada and transported to South Africa without any cost to the Imperial Government.

VIII.—Medals.

The Council have awarded the Society's Silver Medal to the following readers of papers during the Session 1911–12.

At the Ordinary Meetings :—

Algernon E. Berriman, "The Efficiency of the Aeroplane."

Professor G. W. Osborn Howe, M.Sc., M.I.E.E., "Recent Progress in Radio-Telegraphy."

Cecil Thomas, "Gem-Engraving."

H. A. Roberts, M.A., "Education in Science as a Preparation for Industrial Work."

F. Martin Duncan, "The Marine Biological Association, and some account of the Work it has accomplished."

Theodore E. Salvesen, "The Whaling Industry of To-day."

George Fletcher, "Technical Education in Ireland."

E. D. Morel, "British Rule in Nigeria."

Ernest Kilburn Scott, Assoc.M.Inst.C.E., M.I.E.E., "The Manufacture of Nitrates from the Atmosphere."

In the Indian Section :—

J. Travis Jenkins, D.Sc., Ph.D., Superintendent of Lancashire and Western Sea Fisheries, "Fisheries of Bengal."

Hosted by Google

E. A. Gait, I.C.S., C.S.I., C.I.E., Census Commissioner for India, "The Indian Census of 1911."

Sir John O. Miller, K.C.S.I., "The Central Provinces."

Neville Priestley, Managing Director, South Indian Railway, "Indian Railways."

In the Colonial Section:—

W. A. Legg, M.Inst.C.E., "Irrigation in South Africa."

Alan H. Burgoyne, M.P., "Colonial Vine Culture."

Of recent years it has been the practice that no medals should be awarded to readers of papers who had previously received medals from the Society. Acting on this rule the Council were precluded from considering the following papers:—

At the Ordinary Meetings:—

James Douglas, LL.D., "The Industrial Progress of the United States of America"; Cyril Davenport, F.S.A., "Illuminated MSS."; Leonard Hill, M.B., F.R.S., "The Influence of Ozone in Ventilation"; Frank Warner, "The British Silk Industry and its Development since 1903"; T. Thorne Baker, "Some Modern Problems of Illumination—the Measurement and Comparison of Light Sources"; William Burton, M.A., F.C.S., "Ancient Egyptian Ceramics."

In the Indian Section:—

Colonel Sir Thomas H. Holdich, K.C.M.G., K.C.I.E., C.B., D.Sc., "The North-East Frontier of India." Sir Thomas Holdich was also disqualified by the fact that he is a member of Council.

In the Colonial Section:—

The Hon. John G. Jenkins, "Australian Railways."

The Council, however, desire to express their high appreciation of these papers.

IX.—Owen Jones Prizes.

After the death, in 1874, of Owen Jones, the well-known decorator and writer on decoration, a committee was formed to collect subscriptions for the purpose of founding a memorial, and the balance (a sum of £400) was presented to the Council of the Society of Arts upon condition of their expending the interest thereof in prizes to "Students of the Schools of Art who, in actual competition, produce the best designs for Household Furniture, Carpets, Wall-papers and Hangings, Damask, Chintzes, etc., regulated by the principles laid down by Owen Jones." The prizes have now been awarded annually since the year 1878 on the results of the annual competition of the Science and Art Department, and its successor, the Board of Education.

Six prizes were awarded last session (1910–11), each prize consisting, in accordance with the regulations prescribed for the administration of the Trust, of a bound copy of Owen Jones's "Principles of Design," and a bronze medal.

The list of the successful candidates has already appeared in the *Journal.**

The examiners who judged the works submitted for competition report as follows:—

"587 works were sent in for this competition, showing an increase of 146 on last year, and the general level of merit is higher than then.

"The best examples are the Woven, Printed, and Stencilled Fabrics. There is a fairly good representation of the useful class of Damasks, as well as some good Carpets and Embroidery.

"The Examiners regret to find that no examples of Designs for Furniture have been submitted."

As already announced, the next award will be made in the current year. Six prizes have already been offered for competition.

X.—North London Exhibition Trust.

For some years past the interest on the sum of £157, the surplus of the North London Exhibition held in 1864, has been devoted to the award of prizes to students of the Artistic Crafts Department in the Northampton Polytechnic Institute, Clerkenwell. At present an annual sum of £5 is placed at the disposal of the Governors of the Institute. Of this amount £4 only was expended last year, so that a sum of £6 was available for the present year.

The names of the successful candidates were published in last week's *Journal.* The awards have been made on the recommendation of Mr. Alan S. Cole, C.B.

XI.—Examinations.

In the paragraph dealing with the examinations of 1911 in last year's report, it was stated that the Council were considering very carefully what steps they could take to ensure the absolute integrity of the Society's examinations, and to prevent a repetition of that most unfortunate occurrence of last year, when certain teachers were successfully prosecuted for fraudulently obtaining the Society's medals. The Council are glad that they are now able to report that so far at all events as London is concerned, they believe that this object has been attained by their good fortune in securing the valuable aid of the London County

* See *Journal*, September 29th, 1911.

Council Education Committee in the superintendence of the examinations.

As the members are aware, the Society's examinations for the past fifty years have been conducted through the agency of voluntary committees, and it was always felt that these committees could be relied upon for the strict supervision of the examinations. But, to quote a paragraph from last year's report, "the development and competition between the various proprietary institutions which have sprung up of late years, and which it may be added are doing very efficient service in the cause of education, has produced a source of temptation amongst those interested in such institutions, who are anxious to obtain all possible credit for their own schools, and may occasionally be led away to attempt to obtain such credit by illegitimate means." Small as are the temptations to such an illegitimate course, it is yet certain that the stress of competition has occasionally led to fraudulent proceedings. A few such in previous years have been detected and suppressed. Last year it was found necessary to take public action, and this action had the satisfactory result at all events of vindicating the Society's good faith. But so long as the whole supervision of the examinations is in the hands of unofficial committees, who are of necessity associated with the institutions where the examinations are held, it cannot be denied that even though, as is certainly the case, nearly all such committees are far above suspicion, the public cannot be expected to place the same implicit reliance in the results of the examinations as if they were conducted under the supervision of some independent authority.

Negotiations were for some time carried on with the London County Council Education Committee, which is the education authority for the County of London, but it was not until after a good deal of inquiry and considerable discussion that the Committee saw its way to agree with the Society's request. Eventually they did so, and with most satisfactory results. The final conclusion was not reached until a very short time before the date of the examinations, and consequently the arrangements were made under a certain amount of pressure. Nevertheless they worked with perfect smoothness, and it may be said that they gave entire satisfaction to all concerned. This, of course, is not to say that there were not a few complaints of individual hardship; but these were merely infrequent exceptions to the general satisfaction.

The actual changes in the administration were really not considerable, and in no way affected the candidates themselves. The various local committees were asked to send their applications to the L.C.C. Education Office, instead of to the office of the Society. The places where the candidates were to sit for examination were then allotted by the Committee. All the larger centres took their own candidates. The smaller centres were amalgamated, and a certain amount of administrative work was thus saved. The most important change really was that the superintendents for the examinations were appointed by the Committee, and were responsible to it, so that the examinations were for the first time in London conducted under the superintendence of independent officers unconnected with the institutions where the examinations were held. The necessary additional cost was this year borne by the Society's funds; but notice was given that for future years it would have to be provided by a small fee to be paid by the local committees. It is difficult to see that any objection can be raised to this, because the local committees were this year relieved from the cost of providing and paying their own superintendents.

The Council desire to express their appreciation of the assistance which they have received from the London County Council, and their belief that its co-operation will add considerably to the value of the examinations, and to the public appreciation of the certificates awarded to the candidates. A similar co-operation has, of recent years, been arranged between the Society and a large proportion of the educational authorities throughout the country, who have established centres of their own, and have in many cases absorbed previously existing local committees. It is the earnest hope of the Council that this system, which has been steadily increasing during the past few years, may still further develop, and that, especially in the great provincial cities, the educational authorities will fall into line with the London County Council, so that, before long, the Council may be able to report that the whole of the Society's examinations are conducted under official and independent authority.

The large number of candidates entering for the Society's examinations, and the consequent extension of time before the results can be published, have for some years past rendered it necessary to postpone till a later date any detailed report on the examinations of the year. A few figures may be given. The total number

Hosted by Google

of papers worked was 34,006, the number last year being 34,242, a decrease of 236. These were divided among the various stages as follows:—Stage I., 14,936; Stage II., 13,583; Stage III., 5,487. The corresponding figures for 1911 were:—Stage I., 14,286; Stage II., 14,025; Stage III., 5,931.

As usual, further information will be provided in a general report on the examinations which will be published as soon as convenient after all the results have been made public. These results, so far as concerns Stage III. (Advanced) have just been published. The results of Stage II. (Intermediate) will be issued in July, and those of Stage I. (Elementary) in August.

XII.—Practical Examinations in Music, 1911.

The Practical Examinations in Music were not concluded last year until July 10th, 1911, too late for the results to be included in the Report of the Council. They lasted for seven days.

The examinations were conducted by Dr. Ernest Walker, M.A., and Mr. Burnham Horner.

The system of examination was the same as that for recent years. For instrumental music certain standards are given, and candidates are asked to select for themselves which of these standards they choose to be examined in. The standards range from easy to very difficult music. For each standard a list of music is given for study, and from this list candidates select the pieces they will sing or play. Candidates are expected to play or sing the pieces which they have prepared, to play or sing a piece, or portion of a piece, at sight, and to play certain scales.

In all, 289 candidates entered, and of these 283 were examined, a decrease of 56 as compared with 1910. There were 214 passes and 69 failures.

The following were the subjects taken up:—Piano, singing, violin and violoncello. 239 entered for the piano, 182 of whom passed; 37 entered for the violin, of whom 28 passed; 4 entered for the violoncello, 3 of whom passed; 3 entered for singing, of whom only 1 passed. One medal was awarded.

The quality of the competitors was, on the whole, much the same as usual.

XIII.—Practical Examinations in Music, 1912.

The Practical Examinations for the present year commenced on the 22nd inst., and will be finished on July 3rd, after which a summary of the results will be given in the *Journal*. The work of the examination is being carried out by the same examiners as in the last nine years; 300 candidates have entered for the present examinations, an increase on last year of 11.

XIV.—Viva Voce Examinations in Modern Languages.

Up to the present date twenty-four examinations have been held this year in London, Liverpool, and Manchester. Arrangements have also been made for holding examinations at several other centres.

At these examinations 545 candidates presented themselves, of whom 451 passed (182 with distinction) and 94 failed. The languages taken up were French, German, Italian, and Spanish.

The results of previous years are as follows:—

Year.	Number Examined.	Passed.	Failed.
1902	280	202	78
1903	456	324	132
1904	540	375	165
1905	681	502	179
1906	644	469	175
1907	629	476	153
1908	615	467	148
1909	656	506	150
1910	642	495	147
1911	583	463	120

It is satisfactory to note that, if the numbers of candidates do not increase, the standard shows a steady improvement, as the proportion of failures regularly diminishes.

These examinations are held at any of the Society's centres where the necessary arrangements can be made, at any date convenient to the local committee. The examination includes dictation, reading, and conversation, and is so arranged as to test efficiency in a colloquial knowledge of the language, without laying too much stress on minute grammatical accuracy. Candidates who are reported upon as highly qualified by the examiners receive a certificate of having passed with distinction.

The examiners are Mr. S. Barlet and Mr. B. M. Nevill Perkins for French, Professor H. G. Atkins and Professor A. Johannson for German, Mr. J. M. Villasante and Mr. W. F. Bletcher for Spanish, and Mr. Luigi Ricci for Italian.

XV.—The Society's Medal.

It was mentioned in the last Council Report that H.M. King George V., on becoming Patron of the Society, had graciously consented that his head should be engraved on the medal, and had expressed the wish that the work should be carried out by Mr. Bertram Mackennal, A.R.A.

Hosted by Google

The die was prepared from Mr. Mackennal's model by Mr. Allan Wyon, and the new medal is a fine example of artistic workmanship, and also an admirable likeness of the King. The first medal struck was presented to his Majesty, who intimated his warm approval of it.*

During the first century of the Society's existence many medals were used. Perhaps the most beautiful of these was the one designed by Flaxman in execution of the idea suggested by James Barry that the Society's principal medal should have on it the heads of Minerva and Mercury. This medal was executed in 1807, and in that year the first example of it was presented to the designer.

In 1849 the idea was suggested that the medal should bear the head of the President, and permission having been obtained from H.R.H. Prince Albert, who was then President of the Society, a die for the purpose was made by W. Wyon. This medal was employed up to 1861. After the election of King Edward VII., then H.R.H. the Prince of Wales, to the Presidentship in 1863, his head was placed upon the obverse of the medal, the die being also made by W. Wyon. In 1900, the old die being worn, a new die was engraved at his Majesty's desire by Mr. Emil Fuchs. In 1901, when King Edward succeeded to the throne, and became Patron of the Society, he acceded to the request of the Council that his head should still appear on the Society's medal, and this was done, the necessary alteration being made in the inscription. This medal was used until King Edward's death in 1910.

XVI.—Soane Museum.

Under the Act by which the affairs of the Soane Museum are regulated, the Royal Society of Arts have to nominate one of the trustees. The office is held for five years, and the last election having been in 1907, it is necessary that the Society should exercise its power during the present year. The Council recommend for election Sir George Birdwood, who has acted for the last fifteen years, having been first elected in 1897.

In 1833 Sir John Soane presented to the nation the house which he had built in Lincoln's Inn Fields, and in which he had placed his very valuable collection of pictures and objects of antiquarian interest, together with his extensive library. At the same time he obtained an Act of Parliament by which the property was vested in trustees—four appointed by himself, and five by the Corporation of London, the Royal Academy, the Royal Society, the Society of Antiquaries, and the Society of Arts—the four original nominated trustees having the power to fill up by election vacancies in their number as they occurred. The authority of all the trustees is the same, but the property is vested in the life trustees, and they only have the power of signing cheques. Sir John Soane also provided the funds necessary for the maintenance of the house as a Museum. He died on January 20th, 1837, and shortly afterwards the Museum was placed under the authority of the trustees.

The following is a list of the trustees appointed by the Society—

1837 to 1843—H.R.H. the Duke of Sussex, President of the Society.
1844 to 1857—H.R.H. the Prince Consort, President of the Society.
1857 to 1864—Sir Charles Wentworth Dilke, Bart.
1865 to 1876—Samuel Redgrave.
1876 to 1882—Alan S. Cole, C.B.
1882 to 1896—Sir Benjamin Ward Richardson, M.D., F.R.S.
1897 to 1912—Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D.

XVII.—Conversazione.

The Council decided to abandon the holding of the Conversazione this year, and to hold it in future every other year instead of annually. The attendance of late has been much smaller than in former years, when meetings of this sort were less common, and in practice it was found that only a small proportion of the members availed themselves of the privilege. The Council trust, therefore, that their action has met with the approval of the members generally.

XVIII.—History of the Society.

The series of articles on the Society's history, which were commenced by the Secretary in the last volume of the *Journal*, have been continued. In all, eleven articles have now appeared, and they bring the history down to the time when the Society obtained a Charter of Incorporation —1847. It is expected that the series may before long be completed, and it is intended to republish them in the form of a book, which it is hoped may supply the need of a complete history of the Society, since its foundation more than a century and a half ago.

XIX.—New Council.

In accordance with the by-laws regulating the election of the Council, four vice-presidents and four ordinary members of Council retire annually. The four retiring vice-presidents, all

* An illustration of the medal was given in the *Journal* for October 20th, 1911.

Hosted by Google

of whom go out by seniority, are the Earl of Cromer, Sir William Preece, Sir Boverton Redwood, and Sir William White. The four retiring members of Council, partly in consequence of seniority and partly by infrequency of attendance, are Sir George Askwith, Sir Thomas Holdich, Mr. James Swinburne, and Sir Philip Watts.

One retiring member of Council is eligible for election as a vice-president, and the Council have therefore nominated Sir Thomas Holdich to serve in that capacity. The other new vice-presidents submitted for the consideration of the members are Sir William Abney, who has served in previous years, and was Chairman of the Council in 1903–5, and also Lord Cowdray and Sir Henry Mortimer Durand, neither of whom has held office on the Council before.

The new members of Council proposed are Major Percy MacMahon, Sir Philip Magnus, Mr. Alan Campbell Swinton, and Professor Unwin. Sir Philip Magnus is the only one who has previously served on the Council. Major MacMahon is Deputy Warden of the Standards at the Board of Trade, Mr. Campbell Swinton is a well-known electrician and man of science, and Professor Unwin is the eminent engineer, who at the present time fills the office of president of the Institution of Civil Engineers.

As Professor J. M. Thomson has served for five years as a treasurer, the time of his office has expired. In his place the Council put forward the name of Sir William White, one of the retiring vice-presidents.

XX.—Obituary.

The list of losses which the Society has suffered by death is much shorter than usual, and contains less than the usual proportion of distinguished names. One member of the Council died during the session, Dr. Henry Taylor Bovey, who, after a distinguished educational career at McGill University, Montreal, returned to this country in 1909 to take up the post of Rector of the Imperial College of Science and Technology, a duty which the breakdown in his health prevented his discharging for more than a few months. Mr. James S. Neville served on the Council from 1896 to 1898, and on the Indian Section Committee from 1896 to 1901. His name was originally White, and he was a brother-in-law of the late Dr. Mann, who was for many years Secretary of the African Section of the Society. The Earl of Onslow, who had been a member since 1903, had on two previous occasions presided at meetings of the Colonial Section. Sir Francis Powell, a distinguished Conservative Member of Parliament and Churchman, was amongst the oldest members of the Society, which he joined in 1854. Sir John Grinlinton, long associated with Ceylon, for which island he was Commissioner at the Chicago Exhibition in 1893, was a member of the Society's Colonial Section Committee, but of recent years his great age prevented his taking any active part in its work. Sir Charles Bennet Lawes-Wittewronge, son of Sir John Bennet Lawes the famous agriculturist, was well known to Cambridge men of his time as a celebrated athlete, and later acquired considerable reputation as a sculptor. The Maharaja of Cooch-Behar died during his visit to England for the King's Coronation. He was an admirable representative of the ruling chiefs of India, and a constant visitor to England. Sir William Crossley, who with his brother founded the great engineering firm of Crossley Brothers, became a member of the Society in 1884. The work the firm did in the manufacture and introduction of the gas engine was recognised by the award of one of the medals offered by the Society at the International Inventions Exhibition in 1885. Sir James Buckingham, long resident in Assam, was recognised as a high authority on all matters affecting the tea industry. Sir Julius Wernher, the well-known South African millionaire, who devoted so much of his wealth to the advancement of education, joined the Society in 1899. Sir William Zeal, an eminent Victorian politician and at one time Postmaster-General for the State, had been a member of the Society since 1897. Mr. Thomas Colby was at the time of his death the oldest member of the Society, which he joined in 1850. Mr. Henry Oppenheim, for many years a banker and afterwards well-known as a collector of objects of art, was an old member of the Society, which he joined in 1875. Mr. Julius Weinberg was of still longer standing, as he was elected in 1861.

Amongst other names which should be mentioned are Mr. James Aitchison, the well-known optician; Mr. George Wedlake, for long a regular contributor to the *Journal*; Mr. Albert Chancellor, at one time Master of the Coachmakers' Company and Mayor of Richmond; and Mr. G. E. Pritchett, who was at one time a very constant attendant at the Society's meetings.

Notices of the above-named, and of other members of the Society who have died during

Hosted by Google

the past year, will be found in the columns of the *Journal.*

XXI.—FINANCE.

The annual statement of receipts and expenditure was published—in accordance with the usual practice—in the *Journal* last week. It shows the revenue and expenditure for the financial year ending May 31st last, the assets and liabilities of the Society, its investments and the trusts standing in its name.

THE CHAIRMAN (Lord Sanderson, G.C.B.), in moving the adoption of the Report, said it was satisfactory to know that the Society was in a good financial position. It was, however, by no means opulent, and they were not in a position to award the large money premiums which it was the practice to grant in the past. As regards the papers and lectures during the past session, he felt sure that they were quite as interesting and as wide in their scope as in any previous year. They had dealt with most of the questions interesting the public at the present time, including radio-telegraphy, aviation, ventilation, coal supplies, oil engines, meat and textile industries, and also with a question of vital importance to great cities—that of passenger transportation. Besides these, they had had two papers dealing with technical education, and it was satisfactory to note, as evidence of our progress in this respect, that at the present time there were schools in this country to which Continental students came to be instructed. The papers dealing with art subjects had been illustrated with lantern-slides of the greatest beauty, whilst the paper on "The Industrial Progress of the United States" was very remarkable and suggestive. The papers read in the Indian and Colonial Sections extended over a very wide field: one on "The North-East Frontier of India" dealt with a new phase of policy—the question of our relations with China on the Indian frontier. The Juvenile lectures by Mr. Vernon Boys on "Soap Bubbles" would be remembered with vivid pleasure by all who had attended them. He thought the members of the Society were indebted to Sir George Birdwood, too, for his contribution to the *Journal* on the subject of that mystic emblem of pre-historic times—the Svastika. Referring to the examinations of the Society, he said it was quite clear that the value of the medals and certificates awarded by the Society depended a great deal upon the public being assured of the integrity of the examinations, and he thought the Society was to be congratulated on having secured the co-operation of the Education Committee of the London County Council in the superintendence of the examinations held in the County of London. At certain large provincial centres also the examinations were under the supervision of the local educational authorities, and he hoped, before long, that their example would be followed throughout the United Kingdom. He felt sure that any slight increase in expenditure necessary to carry out the work was quite worth while. The increase in the number of candidates taking up foreign languages showed that the British public were realising how essential it was to have a knowledge of Continental languages. He thought their thanks were due to the Secretary for the valuable articles he had contributed to the *Journal* on the Society's early history. They had been extremely interesting, and had brought to light a point known to very few people—that not only had the Society done a great deal to promote all forms of art and industry, but it had also helped in the formation of other societies, who had taken up special branches of work. It would be noted, for instance, that the Society was the first to establish exhibitions of contemporary pictures, and that it also was instrumental in the foundation of the Royal Academy. There was, however, a large field of work still left to the Society to deal with.

LORD BLYTH, in seconding the adoption of the Report, felt sure that the members would agree with him in saying how much they were indebted to the Chairman of Council, as well as to the Secretary, for the services they had rendered the Society during the past year. He thought there was no institution that had done so much work for the good of the Empire as the Society of Arts has done since its foundation a century and a half ago. The Society could not be engaged in better work, and it was their duty at the present time to keep the country well to the front. He had been reminded that members would be doing a real and lasting service by asking their friends to remember the Society when drawing up their wills. It would greatly help the Society to carry on and extend the scope of its work, and he was confident that their bequests could not be put to a better purpose. He had the greatest pleasure in seconding the adoption of the Report.

SIR ARUNDEL T. ARUNDEL, K.C.S.I., asked whether it would be possible for the articles on the "History of the Society" to be reprinted, as this, he thought, would add greatly to their interest.

THE CHAIRMAN said as soon as the series was complete it was proposed to publish the articles in book form. Such a volume would be useful in many ways, and he was sure the members would endorse the action of the Council in promising that any assistance necessary should be given towards the production of the History.

The adoption of the Report was then agreed to.

THE CHAIRMAN proposed a cordial vote of thanks to Sir Henry Trueman Wood (the Secretary), Mr. G. K. Menzies (the Assistant Secretary), Mr. S. Digby (the Secretary of the Indian and Colonial Sections), Mr. George Davenport (the Chief Clerk), and Mr. J. H. Buchanan (Accountant), and to the other officers of the Society for their services.

Hosted by Google

Mr. Robert Kaye Gray said it gave him very great pleasure to second the resolution, which was carried unanimously.

The Secretary returned thanks for this expression of confidence in himself and in the other officers of the Society. He also returned thanks for the kind references which had been made to his work in connection with the Society's early history. He hoped when the articles came to be published in book form that they would be useful in spreading information about many matters connected with the Society which were not generally known to the public.

The ballot having remained open for half an hour, and the scrutineers having reported, the Chairman declared that the following had been elected to fill the several offices. [The names in *italics* are those of members who have not, during the past year, filled the office to which they have been elected.]

President.

H.R.H. The Duke of Connaught and Strathearn, K.G.

Vice-Presidents.

Duke of Abercorn, K.G., C.B.
Sir William Abney, K.C.B., D.Sc., D.C.L., F.R.S.
The Lord Chief Justice of England, G.C.M.G., F.R.S.
Sir Steuart Colvin Bayley, G.C.S.I., C.I.E.
Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D.
Lord Blyth.
Lord Cowdray.
Sir Henry Hardinge Cunynghame, K.C.B.
Right Hon. Sir Henry Mortimer Durand, G.C.M.G., K.C.S.I., K.C.I.E.
Hon. Sir Charles W. Fremantle, K.C.B.
Colonel Sir Thomas H. Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc.
Earl Curzon of Kedleston, G.C.S.I., G.C.I.E.
Sir John Cameron Lamb, C.B., C.M.G.
Sir William Lee-Warner, G.C.S.I., LL.D.
Hon. Richard Clere Parsons, M.A.
Sir Westby B. Perceval, K.C.M.G.
Sir Owen Roberts, M.A., D.C.L.
Earl of Rosebery, K.G., K.T., D.C.L., F.R.S.
Lord Sanderson, G.C.B., K.C.M.G.
Alexander Siemens.
Hon. Sir Richard Solomon, K.C.B., K.C.M.G., K.C.V.O., K.C.

Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D.

On the motion of the Chairman a vote of thanks to the scrutineers was carried unanimously.

Sir Steuart Colvin Bayley, G.C.S.I., C.I.E., proposed a hearty vote of thanks to Lord Sanderson, not only for presiding on the present occasion, but for his conduct in the chair during the past year. He thought the Society were very fortunate in securing Lord Sanderson as their Chairman. They could not have had a more fully informed or more successful Chairman, and considering the demand for Lord Sanderson's services, they ought to congratulate themselves on having his lordship to preside over the Society.

The motion was seconded by the Hon. Richard Clere Parsons, who wished to add his testimony to the interest Lord Sanderson had taken in the affairs of the Society. The duties of Chairman of Council were by no means easy, but the attention his lordship had paid to all matters connected with the Society was remarkable.

The Chairman acknowledged the vote of thanks.

The meeting then adjourned.

THE EXHIBITION OF DESIGNS FOR MURAL PAINTING AT CROSBY HALL.

An exhibition of this kind is bound to be more or less unsatisfactory by the very nature of things, for designs intended for the decoration of a building if properly suited to their purpose cannot show to advantage when exhibited after the manner of pictures, apart from their proper surroundings, and care must be exercised, in judging the merits

Hosted by Google

of a design, to make allowance for the problem that has to be solved in its actual execution. The inherent danger of an exhibition of such work is, in fact, that of focussing too much attention on the actual details of the design as an independent work, whereas it is a truism that its proper function is to form part of the scheme of the building in which it is placed.

One might almost say that the chief value of this exhibition lies in the fact that it brings into prominence how far modern art has departed from this ideal, as a consequence of the prevailing tendency to work for exhibition and the concentration of art teaching on the technique of oil painting. With only too few exceptions the works exhibited may be described as Academy pictures adapted as mural paintings, and it is clearly evident that there is no live tradition of mural decoration in the highest sense of the term.

The exhibition contains two classes of exhibits—a loan collection of designs for works actually executed at various times, and designs submitted in competition for the various commissions offered under the scheme promoted by the Mural Exhibition Committee.

Of the former, many are well-known examples of modern mural paintings, by Walter Crane, Henry Holiday, Frederick Shields, Ford Maddox Brown, and other modern artists. It is interesting to compare these exhibits with the few examples of the work of an earlier generation, such as the sketch for mosaic work by J. C. Hook, R.A., and to note the progress that has already been made in our own times towards the revival of the true principles of mural decoration. It is still more interesting to study the reproduction of English mural paintings of the thirteenth century exhibited by Mr. W. Tristam, and to notice the charming results produced by simple treatment and in despite of limitations in the way of drawing.

The special feature of the exhibition is the collection of competition designs by students. Briefly outlined, the scheme under which these have been produced, and of which the exhibition is an outcome, has the dual object of encouraging students to study the principles of mural painting and of providing them with the necessary opportunities for the execution of such work.

A large and influential committee was formed for the purpose, with Mr. Charles Aitken and Mr. Wilfred Walter as secretaries, and as a result of their work various sites were offered for decoration and funds provided for the execution of approved designs. The work submitted in competition for these commissions is the work of students and must be judged as such, but, as already remarked, the prevailing impression one gathers from their examination is that there is a general lack of appreciation of the problems that have to be faced. There is a tendency to elaboration of detail and concentration on perspective and light and shade, and an absence of the broad and simple treatment essential for the design to harmonise with the building in which it is placed and stand the test of being viewed in all lights and from all distances. This is a tendency one would expect to find as the result of modern training, which is largely based on painting for exhibition, but it is a tendency which must be overcome if really satisfactory mural painting is to be produced in the future.

One can find less excuse for those who exhibit designs which rush to the opposite extreme, and mistake crudeness of drawing and ill-considered execution for simplicity and breadth of treatment. Above all things what is wanted in mural decoration is common-sense, and the introduction of the bizarre and extravagant cannot be too strongly deprecated. The exhibitors we have in mind at the moment seem to have been under the impression that to be simple one must copy the archaic. One has only to compare the designs produced with the reproductions of early work alluded to above to see the fallacy of such reasoning. They have copied the letter and more particularly the faults of mediæval work, but failed to catch the spirit under which it was produced.

One can, of course, only refer to the matter in general terms in this note—it must not be imagined from this general criticism that, taken in detail, there are not many signs of promise. This exhibition is the first of its kind; it will inevitably direct attention to the needs of mural painting and one hopes that considerable progress may result. Some of the results of the competitions have been announced. Three commissions of £100 each were offered for approved designs for the New Gallery of Modern Art at Dublin, the selection to be made by the donor. The designs selected are by Mr. Walter Bayes (No. 28, "Irish Linen"), Mr. Cayley Robinson (No. 23, "The Coming of St. Patrick"), and Mr. James Mark Willcox.

The grant of £100 offered by Mr. Davis for the decoration of the vestibule of the Middlesex Hospital has not been awarded, but £50 has been granted to Mr. Maclaren for his design. The competition offered by the London County Council for the decoration of the school halls at Cable Street and Commercial Street has been won by Miss Jacobs (No. 84, "Prince John Granting the Commune"), and Mr. S. H. North (No. 34, "St. George and the Dragon").

On Tuesday evening, the 18th inst., a meeting was held at the Exhibition under the auspices of the Society of Mural Decorators and Painters in Tempera (which has been recently reorganised with the avowed object of studying the materials and methods of mural decoration and the improvement of the arts of painting in tempera and painting in fresco), when Sir Charles Holroyd presided over a large audience.

Professor Selwyn Image spoke on "The Future of Mural Decoration" pointing out the various problems that had to be solved and difficulties that had to be faced by the movement to ensure its success.

Mr. Walter Crane pleaded for more courage and

Hosted by Google

enthusiasm in grappling with the difficulties and finding the right path, and Mr. Southall, Mr. A. S. Penty, Mr. J. D. Crace, Mr. Halsey Ricardo, Mr. Hallward, and Mr. Noel Heaton contributed to the discussion.

Owing to the interest that has been aroused in this exhibition it has been decided to continue it until the 29th inst. instead of closing on the 22nd inst., as originally arranged.

LORD KITCHENER ON EGYPT AND THE SUDAN.

Lord Kitchener's return to Egypt, after an absence of eleven years, has been now marked by the issue of a report whose general interest is enhanced not only by the attention which he draws to the more important developments effected in the interval, but also by the special part that Egypt plays in the present political position. Almost simultaneously with the British Agent's arrival in the country, the whole situation in the Mediterranean and Northern Africa was rudely disturbed by the Italian invasion of Tripoli and Cyrenaica, which naturally produced much excitement among the Mohammedans. Formerly the more intelligent of these inhabitants constituted a fairly homogeneous body based on fixed social laws, but nowadays, Lord Kitchener remarks, the collective community is split up and divided into parties and factions of a political character, which, in contrast with the party systems of Western life, are inapplicable to Eastern traditions, and do nothing to elevate or develop the intelligent character of an Oriental race.

The future progress of the Egyptians depends on improved methods of agriculture, combined with general education, and this end is powerfully furthered by the newly-formed Agricultural Department of Government, who impart instruction and advice to cultivators, and are establishing experimental farms throughout the country. The fellah remains the same as he has always been, one of the best and most hard-working types of humanity, though somewhat conservative and hardly realising the changes taking place around him. It is difficult for a people who have through many ages always striven for more water, to realise that too much of a good thing may be detrimental. Hence among the more urgent needs of the day are drainage works, to reclaim water-logged areas, increase of cattle, which have decreased through disease to the extent of a quarter of a million animals during the last seven years, a more careful selection of cotton-seed, and new types to replace the old, which have deteriorated. To provide the latter wants, cotton-breeding has been energetically taken up, and Government now supplies the fellah with better seed for planting. With damp, undrained soil, and the indiscriminate destruction of bird life in recent years, the cotton pests have increased enormously and commit frightful ravages on the crops. A commission is sitting under the presidency of Prince Hussein Pasha, and experimenting to discover some practical means of destroying these insects. The monumental work of the Assuan dam is now practically completed, and the immense benefits accruing by the increased irrigation of the country will repay the expenditure many times over.

The indebtedness of the fellah has always been a source of grave economic anxiety, and it is hoped that the spread of elementary education and the extension of savings banks to the villages may eventually enable the cultivator to clear himself of debt. The establishment of cotton markets throughout the country, and the posting of the daily prices of cotton, will conduce to the fellah deriving a better remuneration for his labour.

In 1910 the important experiment was put in hand of transferring the business of education to the provincial councils, funds being provided by a percentage on the land taxes. The councils have taken up the work with enthusiasm, and the result is that a great impulse has been given to education. Formerly, when the conditions of life were still simple, illiteracy was not perhaps felt as a serious drawback, but modern changes have brought the agriculturist, trader, and workman increasingly into contact with the more highly educated sections of the people, and placed them where illiteracy is an ever-growing disability. The Government have shown their confidence in this new system of local education by a grant of £E100,000 to assist the councils in their work of building and equipping schools, which will probably help to make the widespread illiteracy of the fellah a thing of the past.

Two other interesting developments in the educational policy of the country consist (1) in the commencement of a system of commercial education, which will throw open to Egyptians many honourable and lucrative positions in civil life hitherto closed to them, and (2) in the institution of a proper system of civil service examinations for entrance into the Government service, a step which will both raise the intellectual standard of the officials and remove any suspicion of favouritism which, however unjustly, may have existed.

The clog to progress formed by the Capitulations has been often dwelt upon by Lord Kitchener's predecessors, and is only referred to generally in the present report. As to the mixed tribunals, there is no doubt that they are no longer adequate to cope with the large volume of civil and commercial business coming before them. The remedy, in Lord Kitchener's opinion; would appear to lie to a great extent in the reduction of the number of judges necessary to form a chamber, but owing to the difficulty in getting the Powers to agree to reforms nothing can, unfortunately, be done in this direction. With reference to the native tribunals, considerable progress has been made during the last few years, and justice is generally administered by the natives with efficiency and despatch, foreigners often assigning their claims to natives in order to get them dealt with rapidly in the native courts.

With regard to the affairs of the Sudan, the visit of the King and Queen to Port Sudan in January, though not actually falling within the events of 1911, naturally calls for notice, largely in consequence of the excellent effect which the visit produced throughout the country. After the departure of their Majesties, the sheiks and notables assembled at Khartoum to discuss the affairs of the Sudan with Government officials, and it was very evident from their conversation how greatly they had been impressed by the auspicious event.

The population of the Sudan is now estimated at well over three millions, a satisfactory increase over the two millions to which it had been reduced by the fanatical rule of the Mahdi and his successor, coupled with the wars, disease, and starvation brought in its train. From surrounding parts of Africa a constant stream of immigrants, attracted by the peaceful and prosperous condition of the Sudan, is entering the country, so that it may be fairly expected that in the course of the next five years the population will have attained some six millions, and thus doubled its present total.

When we conquered the Sudan there was hardly a single inhabitant who possessed any money, and, with the exception of the fighting men, the whole population was practically starving. In re-visiting the country nothing has struck Lord Kitchener more than the great increase in the individual prosperity of its inhabitants. It is not too much to say that there is now hardly a poor man in the Sudan. Unlike the Egyptian fellah, the Sudan cultivators are not bound down by debts to usurers, the benefits of peace have been fully reaped by the cultivators, and increased facilities of communication have brought to their doors markets hitherto undreamt of. It is, therefore, not surprising that the people are contented, loyal, and happy.

EMPIRE NOTES.

Empire Migration.—The question of Empire migration is becoming increasingly important, as the need of the Oversea Dominions for population is becoming more insistent. Canada and Australia during the past year have drawn largely from the British Isles, but are endeavouring this year to secure still larger numbers of British settlers. And now South Africa is beginning to realise the necessity of meeting the rapid growth of her coloured population, and their development in education and the arts of peace, by a corresponding increase in the number and strength of her white population. So that it would appear that South Africa may, and indeed must, ere long enter the lists as a competitor for the surplus people of the United Kingdom if she is to preserve her standing as a British possession. This fact has been recently accentuated by statistics which show that the natural increase of the coloured races in that country is far greater than that of the white race. Even in those districts which are purely Boer, the rate of increase in the white population is lower than that of the black, notwithstanding that the Boers, like the French-Canadians, are a prolific people. How far these various requirements, important and clamant as they are becoming, can be met by Great Britain and Ireland it is difficult to say, especially in view of the rapid depletion of some of our country districts, but that the necessity of dealing with the question on broad Imperial lines is urgent is undoubted. This fact is further brought into prominence by the report just issued by the Canadian Government, drawn up by Mr. Arthur Hawkes, who paid a visit to this country a few months ago as special Immigration Commissioner, charged with the duty of studying the conditions and possibilities of emigration from these isles to Canada. He calls for an increase of "the sum of immigration" and for the systematising of its methods so as "to secure the maximum efficiency and permanence of the incoming stream." To do this, he advocates the establishment in Canada of a Federal Board on which representatives of the Provincial Governments should sit, under the presidency of the Canadian Minister of the Interior. This may be, and probably is, a wise suggestion from the Canadian point of view, but there is surely a need for some action on the part of the Home Government, in order that the whole question of Empire migration should be so treated as to promote the interests of all the partners in the Imperial bond.

Vancouver to Yokohama.—The energy and ambition of the Canadian Pacific Railway have received a fresh illustration in the proposal so to extend their service to the Orient, by land and sea, as to make it possible to travel from Vancouver to Yokohama in eight days. The present liners to the Orient take, on an average, twelve days, but recently the "Empress of Japan" made the trip in a fraction over ten days, and the improved Trans-Pacific "Empresses," with their guaranteed speed of 18 knots as against the 13-knot boats at present in use, may reduce the time over the route now taken to nine days. Still faster boats, however, may be employed which, with the extension of the railway system from Esquimalt and the Nanaimo branch of the C.P.R. from McBride Junction northward towards Comox, will enable passengers to be conveyed to and from Vancouver and Yokohama in eight days. What with this proposal and their European Continental railway project, and the many schemes—ready-made farms and other land settlement devices—which the management has undertaken, the C.P.R. is setting the pace in a really marvellous manner for all the other great railways of the Dominion.

Canadian Municipal Taxation.—The adoption in Canada of business and income taxes, and the system employed in the assessment of municipal properties, in place of the old property tax, appear to great advantage in Toronto, where the present rate, 18 mills to the dollar—equal to $4\frac{1}{2}d.$ in the £

Hosted by Google

—produces a revenue of a little over six million dollars (£1,200,000). The value of this assessment is considerably in excess of what it was in 1875. In that year the total assessment for taxation was 46,500,000 dollars (£9,300,000), which, at the rate then prevailing of 14 mills to the dollar, produced a revenue of 651,000 dollars (£130,200). In 1912, the total assessment has risen to 343,600,000 dollars (£70,000,000), yielding, as stated above, a revenue of £1,200,000. The 1912 assessment is distributed as follows:—real property (land and buildings), 291,600,000 dollars; business, 38,200,000 dollars; and income, 13,800,000 dollars. The total number of individual assessments is 127,000. The practice in valuing the different classes of property for assessment varies. Real property, in the residential districts, is taken at its full market value, but the business tax represents a fixed percentage of the real assessment, and varies with the class of business. Thus, a distillery would pay on 150 per cent. of the assessment value; a brewery, railway, or financial house, on 75 per cent.; a manufactory on 60 per cent.; professional, on 50 per cent.; retail merchant, on 25 to 30 per cent.; and a large departmental store, on 30 per cent. of the assessment value of land and buildings. The income tax is based on voluntary declaration, but an allowance is made of 1,200 dollars in the case of householders, and 600 dollars for single persons. The rate is struck annually, and is regarded as much more applicable to modern conditions than the old-time property tax.

Canada and the West Indies.—The important trade agreement between Canada and the West Indies, by which it is proposed to establish closer commercial relations between these countries, was signed at Ottawa on April 10th, in the presence of H.R.H. the Duke of Connaught. Before, however, it comes into operation, it will have to be submitted to, and approved by, the West Indian Legislature, and the Dominion Parliament. No opposition is anticipated, as the agreement has been received by the people, both in Canada and the West Indies, with the utmost satisfaction. To give practical effect, however, to the arrangement, one of the most important provisions is that of closer intercourse by improved cable and steamship communication, on which point the conference which adopted the agreement embodied their views in resolutions urging the necessity and importance of active co-operation in the matter between the West Indies, Canada, and the United Kingdom. These resolutions declare that improved cables are required, and that the most acceptable plan would be by extending the cable system from Bermuda to Barbados, Trinidad, and British Guiana, with the necessary provision for inter-island connections. It is recommended that the work should be carried out through the medium of some responsible cable company, which should be secured, for a term of years, against loss or insufficient revenue by a joint guarantee by the Imperial and Colonial authorities. In the same way, co-operation is to be sought for the providing of an efficient service of ships, so arranged as not only to meet the requirements of trade, but to make connection with the Canadian mail steamers, plying between Canadian and British ports. At present the Imperial Government provides £8,000 only for telegraphic communication, as compared with £16,000 in 1907, while for steamer service the grant, which was formerly £98,900, has been reduced to £52,500. It is hoped and believed that this effort to raise the prosperity of the West Indian Islands, with the assistance of Canada, will meet with appreciation on the part of the Imperial Government.

Australian Trade.—The Melbourne *Journal of Commerce* has published some interesting particulars of Australian trade for 1911. In noting that the increased export of Australian produce is satisfactory, it states that, in relation to the expansion in imports or purchases of goods, the position is not so sound as it should be. In view of the fact that there has been very little borrowing from abroad to inflate imports, it thinks that the purchases of merchandise have been excessive, and that the margin of exports has not, of late, sufficed to meet interest obligations, especially if the gold shipments include, as it is suspected they do, a considerable amount of money withdrawn for investment elsewhere. The total value of all imports for 1911 was £66,860,303, compared with £60,014,351 in 1910, an increase equal to 11·4 per cent. Included in this total was gold bullion and specie to the value of £1,991,064, which leaves the value of the net merchandise imported £64,869,239, or an increase equal to 10·55 per cent. on the previous year. These figures constitute a record, and show that the gross imports for 1911 were equal to £14 13*s.* 7*d.* per inhabitant. The gross value of exports to all oversea countries was £79,484,270, or £4,993,126 more than in 1910, which is equal to about six per cent. This amount includes oversea goods re-exported to New Zealand, the South Sea Islands, and other places, to the value of £3,260,393, leaving the net Australian produce at £76,223,677. The shipments of gold and specie included in the above returns were relatively heavy last year, amounting in value to £10,437,675. Deducting, therefore, this amount, the exports of merchandise showed a decrease for 1911 of £2,281,508, equal to 3·46 per cent., as compared with 1910. The value of the gross exports averaged £17 9*s.* per inhabitant. It is evident from these figures, whatever special deductions may be drawn from them, that the volume of Australian trade is increasing rapidly, and that both as a producer and a customer, the continued progress of Australia is assured.

The Western Australian Pearling Industry.—The decision of the Commonwealth Government that only white labour shall be used in

Hosted by Google

connection with the pearling industry of Australia after this year, has already begun to bear fruit. The Pearlers' Association of Western Australia has recently imported from England a number of men to act as divers and tenders. According to the report of the Association, the men engaged appear to be steady and industrious, and give promise of being fully up to their work. The industry itself, despite vicissitudes in the shape of occasional cyclones, continues to be a most profitable one and its prosperity is increasing. In 1910 the total export of pearls and shell amounted in value to £348,911, the largest total recorded in the history of the trade. Complete figures are not yet available for 1911, but an approximate estimate given of the value of the shell exported is £240,764, apart from the value of the pearls, of which no estimate has yet been made. Broome is the chief centre of the pearling industry of Western Australia, but other localities on the north-west coast are extending their trade in this direction.

The Tropical Diseases Bureau.—The Colonial Office has recently issued an important paper respecting the establishment of the Tropical Diseases Bureau, which was first started in 1908 as the Sleeping Sickness Bureau, and which was housed in the premises of the Royal Society. Excellent work has been done by the latter in dealing with the question of sleeping sickness, but it soon became evident that what was done for that disease could be done for tropical diseases generally. It has therefore been determined to extend the scope of the bureau, and to locate it in the Imperial Institute. The new bureau will deal with all exotic diseases, which are prevalent in tropical and sub-tropical regions, and will publish, at frequent intervals, a tropical diseases bulletin. The director will have the help of an assistant director and a number of experts, who will be responsible for the different subjects, and will furnish authoritative reviews and summaries of published papers to appear in the bulletin. In this way the results of the most recent researches into every tropical disease in every country, and of the adoption of new methods of treatment and improved means of prevention, will quickly become available for the remote worker in the tropics. The tropical diseases of animals, which will also be treated, will be reported upon in a separate publication. The bulletins will be provided free to the medical and veterinary officers of India and of the subscribing Colonies. No more important work, in the interests of our Colonial possessions, could be undertaken than that of this bureau. To the Crown Colonies, and even to Australia, its work, supplemented as it will be by that of the various branches or independent bureaus engaged in similar investigations in the tropical and sub-tropical districts of these countries, will be of the greatest value, both for prolonging and saving life, and for the development of valuable tropical industries.

CORRESPONDENCE.

THE METRIC SYSTEM.

With reference to the notice of Colonel Nicholson's book, "Men and Measures," which appeared in the *Journal* of June 7th, the following letter has been received from M. C. E. Guillaume, Director of the International Bureau of Weights and Measures:—

Les adversaires du Système métrique possèdent tout un arsenal d'arguments qui côtoient d'assez près la vérité pour trouver créance et cependant s'en éloignent assez pour créer dans les esprits non prévenus, des notions fort erronées concernant la véritable situation du Système métrique dans le monde.

Tout d'abord, il est rare de trouver, dans les écrits de ces irréconciliables ennemis du système, une liste complète des États dans lesquels il est obligatoire ou légal. Cette liste est pourtant éloquente : la voici pour l'époque actuelle. Le Système métrique est obligatoire en Allemagne, Autriche, Argentine, Belgique, Brésil, Bulgarie, Chili, Colombie, Cuba, Danemark, France, Hollande, Hongrie, Italie, Luxembourg, Mexique, Montenegro, Norvège, Pérou, Portugal, Roumanie, Serbie, Suède, Suisse, Uruguay. La Grèce, le Siam, les Républiques de l'Amérique centrale ont décidé de l'adopter à bref délai à titre obligatoire ; enfin, il est légal en Bolivie, en Égypte, aux États-Unis, dans le Royaume-Uni, au Japon, au Paraguay, en Russie, en Turquie, au Venezuela. Nous aurons tout dit lorsque nous aurons ajouté que, dans plusieurs de ces pays, il est obligatoire pour certains usages, et que, dans la réforme toute récente de ses poids et mesures, la Chine a adopté une unité de longueur exactement égale à 32 centimètres, avec division décimale, montrant ainsi l'intention bien nette de préparer la réforme plus complète qui consacrera un jour l'adoption des unités métriques.

Je ne nie point que la réforme métrique, ainsi qu'y insiste M. Nicholson, n'ait été nulle part spontanée, et que partout il ait fallu une intervention des pouvoirs publics pour l'imposer, mais c'est là le fait de toute réforme à laquelle un grand nombre de personnes sont intéressées, et qui, si elle n'est pas simultanée, entraîne des confusions purement intolérables. Ici, aucune conviction, si profonde soit-elle, de la supériorité d'un système, ne peut remplacer l'action gouvernementale ; le terrain ayant été abondamment préparé par les œuvres scolaires ou par une propagande systématiquement organisée, il faut, pour franchir le dernier pas, qu'à un jour donné, les anciennes mesures soient interdites, pour faire place exclusivement aux nouvelles ; mais la constation de ce fait ne diminue en rien la valeur d'un système devenu déjà presque universel.

Deux autres arguments, qui ont déjà servi, mais ne semblent point encore usés, sont, entre eux, absolument contradictoires. Aux uns on déclare,

Hosted by Google

le Système métrique est un tyran très dur, auquel il faut soumettre immédiatement toute quantité susceptible de mesure, qu'elle soit commerciale ou industrielle, et, pour cette raison, l'introduction du Système dans le Royaume-Uni coûterait aux seuls filateurs, la somme prodigieuse de cent millions de livres (Mr. R. H. Barran à la Chambre des Communes, 22 mars 1907).

Aux autres, on affirme, le Système métrique réussit si peu à s'imposer, qu'en France même, où il fut créé il y a plus d'un siècle, il n'est pour ainsi dire pas employé.

Ces deux arguments ne sauraient être simultanément acceptés que si la passion enlève au jugement son libre exercice; il faudrait savoir choisir entre eux. Mais le fait qu'ils sont exclusifs l'un de l'autre ne les empêche nullement d'être tous deux erronés, comme le démontre surabondamment l'examen des faits.

Le premier part de cette idée, que l'adoption du Système métrique obligerait à régler toute la fabrication industrielle sur des valeurs métriques simples. Mais, où a-t-on vu que la réforme eût de telles exigences? D'abord elle peut, pendant une période transitoire, laisser toute liberté à l'industrie, et ne s'applique qu'au commerce, ensuite, lorsque, dans la deuxième période, elle comprendra la production industrielle, elle n'aura pas d'autre signification que celle-ci: les dimensions des machines ou des objets fabriqués seront exprimées en unités métriques. Là, par exemple, où l'on avait dit 3½ inches, on dira 88. 9 mm., et chacun se comprendra comme auparavant. Sans doute, pendant un temps, les nombres les plus fréquents seront plus compliqués qu'autrefois, mais peu à peu les nouvelles machines seront construites sur des données numériques simples, et là où les dimensions avaient été fixées à 3½ inches, on les arrêtera à 90 mm. ou 9 cm. On n'aura brisé aucune vieille machine, on aura seulement modifié légèrement quelques dimensions dans les machines de construction nouvelle.

Dans bien des cas même, les anciennes dimensions pourront être conservées sans inconvénients. Sait-on, par exemple, quel est le calibre des grosses pièces de marine dans les pays continentaux? 305 mm., c'est à dire assez exactement 12 inches, et maintenant on construit des pièces de 356 millimètres, ou 14 inches. Les dimensions primitivement adoptées par l'Amirauté britannique ont été conservées dans les pays métriques, elles sont exprimées en millimètres au lieu de l'être en inches, voilà toute la différence. Si l'on avait commencé cette construction en France ou en Allemagne, on aurait pris vraisemblablement 300 ou 350, peut-être 260 millimètres, les nombres eussent été plus simples: là serait, au point de vue métrologique toute la différence.

Le second argument n'est pas de meilleure tenue. Il est parfaitement exact qu'en Allemagne, et même en France, la vente au détail se fasse beaucoup au Pfund ou à la livre. Mais qu'est-ce à dire? Livre ou Pfund est le nom abrégé de 500 grammes ou ½-kilogramme. La mesure est légale, sinon le nom, et la vente à la livre est faite conformément aux unités du Système métrique. Je n'irai pas jusqu'à dire que l'on doive chercher à conserver ces vieux mots qui ne sont pas inscrits dans la loi; mais l'infraction au système n'est qu'en surface, et ne touche nullement le fond des choses. Si le système n'est pas complètement appliqué dans la lettre, il l'est du moins dans son esprit. L'habitude populaire est vivace, il faut lui faire quelques concessions.

En Allemagne, au point de vue légal, la question se présente sous un jour particulier. La loi impose les unités, mais est muette sur la nécessité de la nomenclature; en disant Pfund, on n'enfreint pas la loi; la pesée est faite avec des poids métriques vérifiés, c'est tout ce que la loi exige, et il faut juger bien superficiellement les choses pour pouvoir dire que le Système métrique n'est point appliqué.

A ce propos, les étrangers ne distinguent pas toujours assez le langage correct de l'argot (slang); les mots bizarres sont les premiers qui frappent.

Dans les quartiers excentriques des grandes villes, les pièces de cinq centimes, d'un, cinq et dix francs portent couramment les noms de *rond*, *linvé*, *thune* et *sigue*, et les billets, celui de *fafiots*, tout comme, dans les campagnes, la pièce de cinq francs est un *écu*, et celle de dix francs une *pistole*; et, si M. Nicholson avait fréquenté les cercles où l'on joue, il saurait que vingt francs se dit invariablement un *louis*, et qu'à Monte Carlo, la pièce de cent francs se nomme une *plaque*.

Ce sont là des fantaisies qu'il faut savoir tolérer; elles ne constituent pas plus des infractions graves au Système métrique ou monétaire que les mots *melon* ou *tube*, ou même *galurin* ne constituent des infractions graves aux principes de la chapellerie; ou, à Londres, les mots "tube" et "bus" une atteinte aux réglements sur les transports.

Tout en désirant la parfaite correction du langage, ne peut-on faire un sacrifice à ces habitudes chères au peuple? Et n'est-ce point en insistant outre mesure sur ces incorrections que l'on mériterait le reproche emprunté à Napoléon, et que rappelle M. Nicholson: "It is tormenting the people for trifles!" Au moment de la réforme métrique, on a peut-être un peu tourmenté le peuple; mais c'était alors pour une chose fort sérieuse; une énorme économie par la simplification à l'extrême dans tout ce qui est susceptible de mesure; c'est maintenant que les "trifles" pourraient commencer. Le temps sera ici le plus sûr réformateur; le fond est obtenu; tout en insistant sur la forme, sachons y appliquer un peu de patience.

CH. ED. GUILLAUME.

OBITUARY.

ROBERT VIGERS.—The Society has lost one of its oldest members by the death of Mr. Robert Vigers, which took place on the 22nd inst., in his eighty-

sixth year. Mr. Vigers joined the Society as long ago as 1858, and in 1909 the Council elected him an honorary member.

Mr. Vigers, who only retired from practice some four years ago, was well known in the City as a land agent and surveyor. In addition to their large private business, his firm was frequently consulted with regard to the compulsory acquisition of land for public purposes. He acted in connection with the purchase of land required by the London, Chatham and Dover Railway from Beckenham into London; he was retained in the matter of the purchase of the telegraphs by the State, the acquisition of tramways by local authorities in all parts of the kingdom, and in the extension of the Great Central Railway to London. He was also arbitrator in many of the Manchester Ship Canal claims, and he was engaged in innumerable assessment appeals.

Mr. Vigers was President of the Surveyors' Institution in 1898, and originated the benevolent fund of that body. He served on the committee of the Estate Exchange, and was a member of the Land Surveyors' Club and of the Surveyors' Association.

GENERAL NOTES.

Mineral Production of Canada, 1910.—The total value of the mineral production in Canada in 1910, according to the annual report of the Canadian Department of Mines, was $106,823,623. This figure, compared with the total for 1909, shows an increase of 16 per cent., and is the largest increase that has been recorded in any one year. Coal occupied the first place, contributing about 29 per cent. of the total; silver came second, with over 16 per cent.; nickel came third, with over 10 per cent.; gold fourth, with 9½ per cent.; clay products contributed 7 per cent.; copper, 6·6 per cent.; and cement, 6 per cent. The increased production was distributed well throughout the list of ores and minerals. Amongst the metallic products the principal increases were in silver, nickel, gold and copper, there being a falling-off in the production of lead and zinc. There was an increase of pig-iron from blast-furnaces, but a decrease from Canadian ore.

Iron and Steel Institute. — The autumn meeting of the Iron and Steel Institute will be held at Leeds from September 30th to October 4th, 1912. An influential reception committee has been formed with Lord Airedale as chairman. A number of papers will be read and discussed, and visits will be paid to works and places of interest in the neighbourhood.

Importation of Vines to Russia.—During the last few years considerable quantities of vines have been imported to the South of Russia. A recent report of the French Consul at Odessa states the number of rooted plants as well as grafts and cuttings of the vine, which in 1908 amounted to 2 million plants and 100,000 grafts, had increased to 4 millions and 1,300,000 respectively in 1911. In 1909, however, the number fell to 800,000 plants and about ¾ million grafts and cuttings, whilst during the following year 2½ millions of the former and 1,380,000 of the latter were imported. The districts of the Caucasus are not included in these figures.

Japanese Tea Production.—The cultivation of the tea plant, which is a shrub with an average life of fifteen years, is general throughout Japan; the area devoted to it aggregates 123,062 acres. The Prefectures of Shidzuoka, Saitama and Miye, are the principal suppliers to the export trade, while Kyoto, Nara and Gifu largely supply the home market. Kumamoto, Fukuoka, and Kochi Prefectures produce black teas. At the time of picking the leaves are fired once, and then sent to the factories, which are usually located near the export markets. Here the tea is refired and cured, and prepared for shipment and consumption. The export centres of Japan are not numerous, there being only six of importance—Yokohama, Kobe, Moji, Shimidzu (the port of Shidzuoka), Yokkaichi (for Miye exports), and Nagasaki. Tea is grown in every prefecture of the main archipelago, except the most northern one, Aomori. The quantity of tea shipped from Japan in 1911, amounted to 43 million pounds. The United States is the largest importer of Japanese tea.

Bee-farming in New Zealand. — The production of honey in New Zealand during the last few years has shown a rapid increase, and so much interest is now being evinced in bee-farming that it seems likely the industry will attain considerable proportions. There are approximately 16,000 keepers of bees scattered over New Zealand. The total exports of honey for the last two fiscal years were: 1909–10, 28,000 lbs., valued at £920; 1910–11, 116,000 lbs., valued at £2,350. The industry has received great assistance from the passage of an Act, some years ago, requiring Government inspection of all the apiaries in the country, forbidding the use of box hives, and compelling the destruction of all disused colonies of bees. There are four Government inspectors at present. Up to the time of such Government regulation, the disease of foul brood was so prevalent throughout New Zealand as to render impossible any successful development of the bee-farming industry, notwithstanding the great advantage of climate and the large areas of land sown in clover. To encourage the industry, the New Zealand Government has established model apiaries at Ruakura and Waerenga, in charge of expert beekeepers, whose duties include the instruction of students of bee culture. Very interesting demonstrations are given at these model apiaries, including preparation of by-products, such as mead and honey vinegar, from odd scraps of honey and broken honeycombs.

NOTICE.

INDIAN SECTION COMMITTEE.

A meeting of the Committee of the Indian Section was held on Wednesday afternoon, the 3rd inst. Present:—Sir William Lee-Warner, G.C.S.I. (Chairman of the Committee), Sir Arundel T. Arundel, K.C.S.I., Sir Steuart Colvin Bayley, G.C.S.I., C.I.E., Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D., Sir Valentine Chirol, Sir Steyning William Edgerley, K.C.V.O., C.I.E., Sir Krishna Govinda Gupta, K.C.S.I., Sir James John Digges La Touche, K.C.S.I., R. A. Leslie Moore, I.C.S. (Ret.), Carmichae Thomas, Sir James Thomson, K.C.S.I., M.A., with Sir Henry Trueman Wood (Secretary of the Society), and S. Digby, C.I.E. (Secretary of the Section).

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

THE MEAT INDUSTRY.*

By Loudon M. Douglas, F.R.S.E.,
Technical Adviser on Animal Industries.

Lecture I.—Delivered February 5th, 1912.

The Bullock and its Products.

In addressing this representative gathering on the subject of the meat industry, I should like, first of all, to invite attention to some general considerations which affect the whole subject.

The meat industry is one of the oldest known to mankind, and the handling of meat in various forms has been practised since long before historic times; but there have been many changes in the art of handling meat and meat products throughout the different ages, and the student of the subject cannot but be struck with the fact that in earlier times there was no such thing as organisation in the meat industry, and very little recognition. There never has been any attempt to supply systematic education to the meat industry in the same way as has been provided for other branches of the food supply, such as dairying, notwithstanding the fact that the ramifications of the meat industry are far beyond those of any other food products. As we proceed, it will become evident what this absence of organised technical education in the meat industry means to this country, and we will endeavour to compute what would be the gain if matters were arranged otherwise.

In the meantime it may be well to remember that much progress has been made in the organisation of meat purveyors during the last quarter of a century. During that time the National Federation of Meat Traders' Associations of the United Kingdom has come into existence, and has united the common interests of the industry all over the country by means of some 150 different local associations with a membership of over 20,000. Such an organisation has immense power in its hands, and it remains to be seen whether its future policy will be an enlightened one with regard to this question of technical education as well as to other subjects, to which we will refer in their proper place.

The Extent of the Meat Industry.

Few people realise the fact that the meat industry is one of the largest in the world. It is really a higher development of agriculture, inasmuch as the meat handler takes charge of the live-stock of the farm when the farmer is finished with it. Some idea of the vastness of the subject may be gathered from the statement that in Europe alone we have over 121,000,000 cattle.* In North America there are approximately, 80,000,000; in South America about

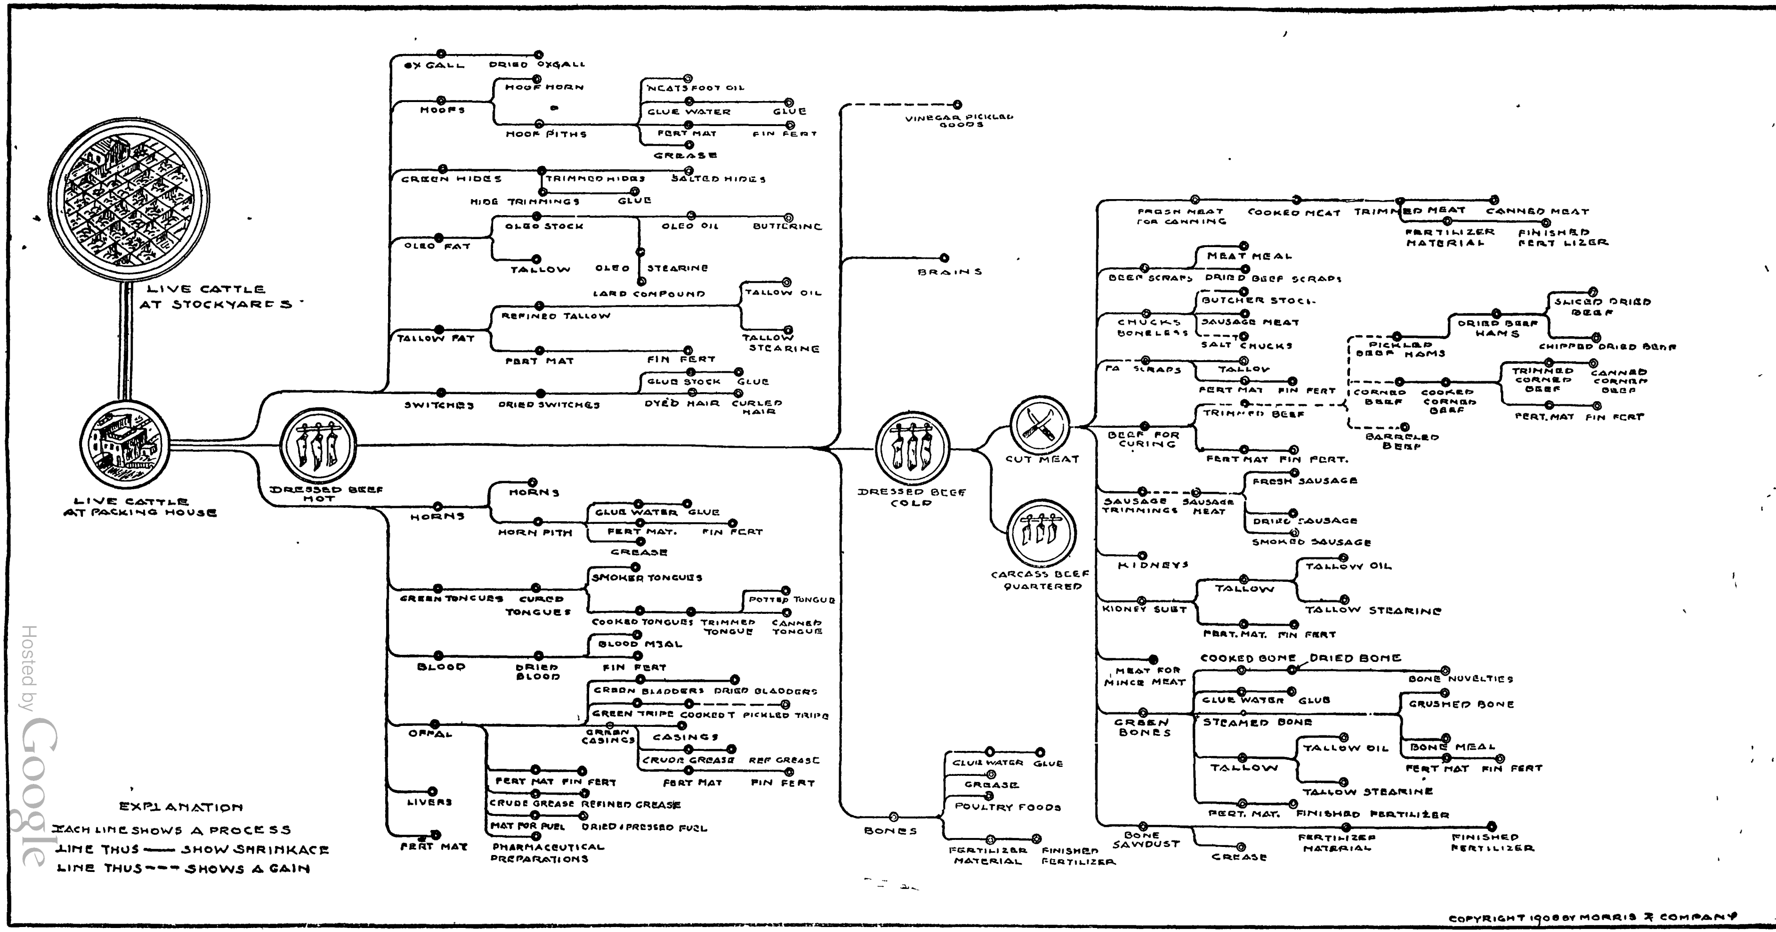

FIG. 1.—DIAGRAM SHOWING THE VARIOUS PRODUCTS DERIVABLE FROM A BULLOCK.

43,000,000; in Asia, 97,000,000; Australia, 12,000,000; Africa, 1,250,000, and these areas may be looked upon as the principal cattle-producing countries in the world, the total supply in all of them being computed at 255,451,985. These are colossal figures, which are really beyond the ordinary comprehension, but they serve to emphasise the fact that while there is such an enormous supply of cattle throughout the world, we in this country are the largest buyers of meat products per head of our population; and it is a remarkable thing that while the meat products from overseas continue to come to this country in increasing quantities from year to year, our own cattle population remains pretty stationary at about $11\frac{3}{4}$ millions,* of which it is computed that we slaughter about 25 per cent., or something under three millions per annum. But the cattle so handled in this country are utilised almost exclusively from the point of view of the meat purveyor, and not from the point of view of the packing-house. That latter idea has yet to be developed in this country, and there are not wanting signs that many people are of opinion that it is a feasible proposition. In the United States there are 936 packing-houses,† and a great many of these came into existence and have developed largely through being able to ship their products to Europe and principally to British markets. Of cattle alone they handle something like 8,000,000 per annum, and while that is a large number, and is constantly on the increase, the exports are becoming smaller and smaller, owing to the increase of the population of the United States and the local demands. These fluctuations in the sources of supply of foreign meat have led to many curious results, which, in so far as the United Kingdom is concerned, have meant that while the meat supplies from North America have dwindled, they have increased enormously from South America. It would seem, however, that if the United States cannot supply large quantities of meat products to the United Kingdom, the packers of that federation are determined still to make a bid for British trade, and one of the recent steps which a number of American packers have taken, has been the purchase of 9,000,000 acres of land in Brazil* for the purpose of ranching cattle and other live-stock, so as to supply the increasing demands in Europe and the British markets.

* The total number of cattle in Great Britain, according to the agricultural returns for 1911, was 7,114,264, and according to the agricultural statistics of Ireland for the same year the number in that country was 4,688,888.

† *The National Provisioner*, January 20th, 1912. Report of Mr. Secretary Wilson's address at the Annual Convention of American Packers.

Imports of Foreign Meats.

We have seen that the home supply of beef is a comparatively steady one, but we are bound to take note of the fact that the imports are steadily on the increase, and amounted in 1911 to a total of fresh and refrigerated meats of 7,362,434 cwts., being the largest quantity on record. The value was £11,136,223, but this was considerably less than the previous year, for causes which we need not examine here. The main feature to note is that the supplies brought are steadily on the increase,† and came from overseas countries where the handling of meat products has been most highly developed, and where the greatest possible care is taken to utilise all the residual products.
